**Flaps as High Lift Devices**

- Landing Setting
  - $30 \leq \delta_{\text{flap}} \leq 60$
  - $C_{L_{\text{Land}}} = C_{L_{\text{max}}}$
  - Lower Landing Distance ✓
- Takeoff Setting
  - $15 \leq \delta_{\text{flap}} \leq 30$
  - $C_{L_{\text{TO}}} = 0.80 C_{L_{\text{max}}}$  ✓
  - Better climb performance

The slide includes two photographs of aircraft wings. The top photo shows a wing with flaps fully extended, marked with a red checkmark. The bottom photo shows a wing with flaps partially extended, also marked with a red checkmark.

Flaps as we all know are using high lift devices, and during landing we have a very large deflection as can be seen here there is a very large deflection typically between 30 to 60 degrees, and the  $C_L$  at landing is normally the  $C_{L_{\text{max}}}$  and the aim is to lower the landing distance during takeoff the flaps are deflected at lower angles as you can see here, the deflection angle of these flaps are lower than that you see in the landing typically, the angle of flap deflection would be 15 to 30 degrees.

So, one can assume that the  $C_L$  at takeoff is going to be 80% of  $C_{L_{\text{max}}}$ , because the deflection of the flaps is at a lower angle and the purpose of using flaps during takeoff is to have a better climb performance.

(Refer Slide Time: 01:07)

But, there are also many different types of flaps and each of them has got a different effect on the lift coefficient. These are some of the standard flap sections that you would use. So, for example, if you have a basic flap, basic aircraft suppose you have a basic wing whose  $C_{Lmax}$  is equal to A this is our baseline let us see how the usage of flaps and that 2 different type of flaps increases the value of  $C_{Lmax}$  from A. So, with a plain flap you can have 50% higher value of  $C_L$  just by deflecting a plain flap.

If you have a split flap you can get slightly better up to 60% higher, this is because we are not spoiling the flow on the upper surface we are only creating a deflection of the flow on the downward surface as compared to the plain flap. If you have a slot in the flap then you are allowing the air from here to actually go and flow over it. So, you can get slightly higher you can get maybe 65% higher value of the  $C_L$  and if you use a Fowler flap in which not only does the flap deflect down with a gap.

But also moves backward resulting in an effective increase in the surface area then you can almost double the  $C_L$  coefficient of to order 1.9. And if you have a basic wing section like this, if this is the left corner of the basic wing section, using a flap is going to lead to a parallel line and at all angles is going to affect the increase in the lift. Similarly, if you look at the  $C_D$  versus  $C_L$  curve, so, if you have a basic wing line as shown here, then you go for a tilt when you include flaps in the aircraft.

**Types of flaps- 4/4**

 Movable slat	60%	22°	Controls boundary layer. Increases camber and area. Greater angles of attack. Nose-up pitching moment.
 Slat and slotted flap	75%	25°	More control of boundary layer. Increased camber and area. Pitching moment can be neutralized.
 Slat and double-slotted Fowler flap	120%	28°	Complicated mechanisms. The best combination for lift. Inlet slots may be used. Pitching moment can be neutralized.
 Blown flap	80%	18°	Effect depends very much on details of arrangement.
 Jet flap	90%	?	Depends even more on angle and velocity of jet.

Now, if we want to sequentially look at the effect of different type of flaps. So, if the basic airfoil you know this is the same information but now placed in a more detailed fashion. And as I mentioned a Fowler flap can lead to almost 90% increase in the lift coefficient. Notice that these are only approximations because the actual increase depends on the geometry of the airfoil also. If you go further and if you start putting now slots in fowler flaps, you can go for a higher increase.

Let us look at now some leading edge devices. So by using a Kruger flap, which is basically a flat curved plate with some kind of rounded leading edge, you can get 50%, if you put a slot you get 40%, a fixed flat with a gap in between can give you around 50% increase and as you keep on moving and as you keep on increasing the complexity of the system you get more and more benefits. For example, if you look at this configuration, where you have a slat and you have a double slotted Fowler flap, you can get around 120%; increase in the lift coefficient. But this is basically a complicated system. So, you have to be careful about use of flaps.

### Typical Values of Max. Lift Coefficient

□ Unflapped wings	
• Swept wing ( $\Lambda_{0.25c} = 60^\circ$ )	0.75
• Swept wing ( $\Lambda_{0.25c} = 45^\circ$ )	1.00
• Unswept wing	1.50
□ Flapped Wings	
• Plain Flap	1.75
• Slotted Flap	2.25
• Fowler Flap	2.50
• Double Slotted Flaps	2.75
• Double Slotted Flaps and Slats	3.00
• Triple Slotted Flaps and Slats	3.50
• Blown Flaps	$\approx 5.00$

Because improvements do not come without any problem improvements always come up with some kind of a compromise. So, this table sums up the typical values of the maximum lift coefficient. So, if you do not have the actual data available, and if you just know the type of the flap for example, if you are told that the aircraft is using double slotted flaps and slats, you can just use this value as a good starting value to calculate the to estimate the max lift coefficient.

This graph from Raymers textbook shows 2 things. It shows that different flaps types have higher values of  $C_{L,max}$ . And it also shows how these values reduce with the increase in the quarter chord sweep. So you can use this graph for the wings of moderate aspect ratio only. And with this graph, you know you can probably get something like if the sweep is 40 degrees, and the flap type is

Fowler, then you can get the value of  $C_{Lmax}$  that you can take from the graph. Thanks for your attention. We will now move to the next section.
