Trajectory Transfer (Contd.)

We have been discussing about the trajectory transfer in the last lecture, so, we continue with that. So, this time we are going to discuss about the transfer between two coplanar circular orbits.

(Refer Slide Time: 00:31)

So, let us assume, we are given one orbit, in which the satellite is currently moving, whose radius is r_i and we have to transfer the satellite from this orbit to another orbit in which the radius is r_f . And let us assume, that the satellite is here in this place and this is to be moved to the point v , along this trajectory. So, we have to find out, what will be the eccentricity of this orbit in which the satellite will be transferred. This is the transfer trajectory and we have to find out the eccentricity of this orbit.

So, if we extend, this orbit it, it looks like this, as shown shown by the dotted line. So, we can write r_f divided by r_i , this is equal to n , is the ratio of the final radius of the final orbit and ratio of the initial orbit, radius of the initial orbit. And this quantity; obviously, it is obvious that it will be less than one. And perigee we can see here, from this place. So, the apogee of the transfer orbit; apogee is the farthest point from the center of the force. So, you can see this apogee lies here. So, the apogee distance is of the transfer orbit is larger than the initial orbit. So, we can write, $r_{\text{apogee of transfer orbit}}$, this will be greater than r_i initial. Similarly $r_{\text{perigee of the transfer orbit}}$, this will be less than r_f .

So, this is the perigee point of the transfer orbit, from here to here and this line extends from here to here. This is $r_{\text{apogee of transfer orbit}}$ and this is $r_{\text{perigee of transfer orbit}}$. So, if basically what we are interested in, we have to show what will be the minimum eccentricity of this transfer orbit and we have to find out under which condition that is going to happen.

(Refer Slide Time: 03:44)

Handwritten derivation on a blue background:

- Top left: $r_p \leq r_f$
- Below it: $\Rightarrow \frac{l}{1+e} \leq r_f$
- Further down: $r = \frac{l}{1+e \cos \theta}$ with $\theta = 0$ below it.
- Diagram: An ellipse with a central point. A line from the center to the rightmost point is labeled "perigee line". The distance from the center to the rightmost point is labeled r_p . The distance from the center to the leftmost point is labeled r_a .
- Top right: $r_a \geq r_i$ (boxed)
- Below it: $\frac{l}{r_f} \leq 1+e$
- Then: $\Rightarrow e \geq \frac{l}{r_f} - 1$
- Then: $\Rightarrow e \geq \frac{r_i/r_f}{r_f/r_i} - 1$
- Then: $\Rightarrow \boxed{e \geq \frac{l}{n} - 1}$
- Bottom: $\text{When } \frac{l}{r_i} = 1 \text{ and } \frac{r_f}{r_i} = n.$

Logos: NPTEL (bottom left), 22-2 (top right), ©CET I.I.T. KGP (top right).

So, we write here. So, we will write in short, r_{perigee} we will write as r_p . So, this is going to be less than equal to r_f , and similarly r_{apogee} this will be greater than equal to r_i . So, $r_p \leq r_f$, we can write now. This implies and you know that, from where we are getting it. Already we know that r can be written as r equal to l by 1 plus $e \cos \theta$, where θ is measured from the caps line. So, if we have the center of force here, and this is the perigee line, which is also called the abline, perigee line and this is the

angle theta here measured. So, and this is the radius r, so, r can be written in terms of semi latus rectum which go r is equal to l divided by 1 plus e cos theta. So, if theta is equal to 0 that gives the length of the perigee. So, this r p we have replaced by putting theta equal to 0. So, put theta equal to 0 and you will get the quantity which is written here.

So, l by r f we can write this as, this will be less than 1 plus e. And this implies e will be greater than l by r f minus 1. And this can be written as l by r i divided by r f by r i minus 1. And this implies e is greater than, now l by r i we will write as l cap and r f divided by r i we write as n. So, this quantity can be written in this way, where l bar r i this is equal to l cap and r f by r i this is equal to n.

(Refer Slide Time: 06:21)

Handwritten mathematical derivation and diagram on a blue background. The derivation shows the relationship between r_a , r_i , l , e , and n . It includes a diagram of an ellipse with semi-major axis a and semi-minor axis b . The diagram shows the perigee (r_p) and apogee (r_a) positions. The semi-latus rectum l is also indicated. The diagram is labeled with e for eccentricity and n for the semi-major axis.

Handwritten notes and equations:

- $r_a > r_i$
- $\frac{l}{1-e} > r_i$ [obtain by putting $\theta = 180^\circ$ in equation]
- $\Rightarrow \frac{l}{r_i} > 1-e \Rightarrow \frac{l}{r_i} > 1-e$
- $e > 1 - \frac{l}{r_i}$ (Equation 3)
- $e = \frac{1}{n} - 1$
- In this area Both the Eqs. (2) and (3) are satisfied.

Similarly if r_a is greater than r_i , which we have already written. So, r_a can be written as l by 1 minus e and this we obtain by obtained by putting theta equal to 180 degree in equation. Thus number this equation, this equation we can write as equation number 1. And this equation we can write as equation number two. So, if we put theta equal to 180 degree. So, we get here minus sign in this place. So, for theta equal to 180 degree; means you are measuring from this position to this position and for theta equal to 0 this is just coinciding with this line. Therefore, for 180 degree you get the perigee position. So, for apogee position this is r_a , and this is your r_p . Hence, in the similar way you can write l by r_i , this is greater than 1 minus e , this implies and l by r_i we have written as l cap. So,

l cap becomes greater than $1 - e$ or e can be written to be greater than $1 - l$ cap. This we write as our equation number 3.

So, now, we can plot equation number 2 and 3. So, l cap verses e , if we try to plot, in the equation number 1, we have e is greater than l by n minus one. So, if we plotting do the plotting. So, you can see there, that if l equal to 0, if we put the equality sign here, e equal to l cap divided by n minus 1, so, you get here putting e equal to; l equal to 0, so, at that time this vanishes and what you get is e equal to minus one. So, by putting l cap equal to 0 means we are in this position and then at that time the value of e equal to is minus 1. So, this is minus one.

And slope of this curve is obviously, positive. So, this slope, it will look like, this curve will look like this. So, this curve is your e equal to l cap divided by n minus 1. And e is greater than and the quantity: the eccentricity is greater than l by n minus one on the upper side of this. So, we have this region in which the inequality sign is satisfied. So, inequalities is satisfied in this region.

Now the next curve we take e greater than $1 - l$. Again if we put l equal to 0, so, the for the the equality sign we can see that e equal to 1. So, this gives you the curve with $\cos$. At l equal to 0 it start here in this place. So, this is again e equal to 1 here in this place and the slope of this curve will be minus one. So, this curve will appear as somewhat in this way. And again the region in which, so, if, let us first tag it here this is e equal to $1 - l$ cap. So, the region in which e is greater than $1 - l$, so, that region will be shown by this line. So, the area in which both these conditions are satisfied; the equation number 2 and 3 both are satisfied. So, this is the area; in this area both the equations 2 and 3 are satisfied. So, this implies that you can choose eccentricity in this region to satisfy the condition that we are started with, that we are sending the satellite from point A to point B along this trajectory, so, such that the perigee is less than the radius of the final or a if this final orbit and the apogee of the transfer orbit is greater than radius of the initial orbit.

So, from here what we get? The point where the two line intersects this gives you the point of minimum eccentricity, the point of minimum eccentricity eccentricity we can. So, if the transfer orbit cannot have less than eccentricity less than this value. So, we need to find out this value, how much this will be.

(Refer Slide Time: 13:04)

therefore for min. eccentricity

$$e = \frac{1}{n} - 1 = 1 - \frac{1}{n}$$
 [from eq. ② & ③]
 By taking equality sign.

$$\frac{1}{n} + \frac{1}{n} = 2$$

$$\frac{1}{n} \left(\frac{n+1}{n} \right) = 2$$

$$\Rightarrow \frac{1}{n} = \frac{2n}{n+1}$$

$$e = 1 - \frac{1}{n} = 1 - \frac{2n}{n+1}$$

$$= \frac{n+1-2n}{n+1} = \frac{1-n}{1+n}$$

$$e_{\min} = \frac{1-n}{1+n}$$

$$= \frac{1 - r_f/r_i}{1 + r_f/r_i}$$

$$e_{\min} = \frac{r_i - r_f}{r_i + r_f}$$

So, therefore, for minimum eccentricity we can write e is equal to $1 - \frac{1}{n}$, this must be equal to 1. This is from equation 2 and 3 by taking equality sign. Solving this will give you $1 + \frac{1}{n} = 2$. And this gives you $n + 1$ by n this equal to 2, and this implies 1 is equal to $2n$ by $n + 1$. And therefore, e can be written as $1 - \frac{1}{n} = 1 - \frac{2n}{n+1}$. So, this becomes $n + 1 - 2n$. So, $1 - n$ divided by $1 + n$. So, the minimum eccentricity because this the minimum eccentricity we get for this point, so, this point is obtained from getting the intersection of these two lines. So, that these lines are defined by these equations which they are obtained; from the equation number 2 and 3 by taking the equality signs.

So, the same thing we have done mathematically here in this place. So, this $e_{\min}$ eccentricity will be $1 - n$ divided by $1 + n$ and in of course, we have written it as r_f by r_i . So, this becomes. So, the minimum eccentricity depends on the radius of the circular orbit in which the satellite is moving the initial and the final one. So, we can see from this place, and also it will be very visible from this point, that how the eccentricity will look like from these figures, let me show it.

(Refer Slide Time: 16:07)

So, this is the supposed transfer orbit that we are choosing. So, we have started point a and this is the point b, now for this can we find out the eccentricity from this figure? So, if you try to do it, so, you can write this r perigee here, this is equal to r f and r apogee you can write as r i. Now we know that, r perigee, this can be written as a times one minus e; where e is the eccentricity; a is the semi major axis of the this ellipse, which is the transfer orbit in this case and also we know that r apogee equal to a times one plus e. So, from here, if we take the ratio, r apogee minus r perigee divided by, or simply you take the ratio here r perigee by r apogee, so, this becomes 1 minus e plus 1 plus e. Now you use component and dividend. So, from there you can write as, now we can take the inverse of this first. So, let us write it in this way r p r a by r p equal to 1 plus e by 1 minus e and now apply component o dividend o. So, this will give you're a minus r p divided by r a plus r p, this will be equal to 1 plus e minus 1 plus e divided by 1 plus e plus 1 minus e. You can see this this cancels out and this becomes 2 e divided by this this cancels out to this is equal to e and the. So, the equation that we have got here r a minus r p divided by r a plus r p equal to e, r a minus r p divided by r a plus r p this quantity equal to e now already we wrote r a equal to r i and r p is equal to r f.

(Refer Slide Time: 19:19)

The image shows a handwritten derivation on a blue background. At the top right, there is a circled number '22-6' and a small logo for 'CET I.T. RGP'. The main equation is
$$\frac{r_a - r_p}{r_a + r_p} = e$$
 Below this, there is a boxed equation:
$$\Rightarrow \frac{r_i - r_f}{r_i + r_f} = e$$
 To the right of the boxed equation, there is a handwritten note: 'eccentricity of the transfer orbit' and 'this is the min. eccentricity transfer orbit' with a horizontal line underneath. In the bottom left corner, there is a small logo for 'NPTEL'.

So, we have written r_a equal to r_i and r_p is equal to r_f . So, this is what we get from this figure, that the ellipse in which the earth satellite is being sent, which is the transfer trajectory here. So, its eccentricity will be given by this. So, this is eccentricity of the the transfer orbit. Now pick up the equations that we obtained. So, this equation we can number it as equation number 4. So, this is the minimum eccentricity possible eccentricity we found out, that if the initial radius is given the and the final radius is given the of the circular orbit then the transfer orbit will have minimum eccentricity which will be given by this equation.

And now you compare this equation and this equation. So, both the equations are same. So, this implies that the minimum eccentricity orbit that you are choosing, it will start at a tangentially and it end at a tangentially; means this the transfer trajectory which is an part of a ellipse from this place to this place, it will touch here in this point and touch here in this point. So, this is cotangential here in this point and in this point. So, this is the minimum eccentricity transfer orbit.

(Refer Slide Time: 22:01)

Now the way we have treated this problem; in the same way we can start with the inner orbit, if the satellite is moving in an orbit of radius r_i and it is to be sent into an orbit of higher radius which is given by r_f . So, we can start at any point say A and send the satellite into this orbit, and we want the satellite to move along certain trajectory. So, this is the point B. So, proceeding in the same way we can prove that the result that we have obtained at, if the satellite starts in this place instead of this place, and it hence appear tangentially in this place, then the eccentricity of the transfer orbit will be minimum. So, now, proceeding in the same way, n is equal to, we define as r_f by r_i , in this case this is greater than one, which is very obvious from the figure and r_p is r_{perigee} r_{perigee} is less than r_i .

So, from there we can write a by $1+e$, this is less than r_i and a by r_i equal to $1+e$, this is less than $1+e$ and this implies e is greater than $a/r_i - 1$. And this is our equation number write from this as 5. Similarly r_a , this is the apogee of transfer orbit, so, this is the r_a is greater than r_f . And r_a , we have written as $a/(1-e)$. This implies a/r_i divided by r_f/r_i is greater than $1-e$.

(Refer Slide Time: 24:37)

And this implies l cap by n , this is greater than 1 minus e . This implies e is greater than 1 minus l cap by e . Again we plot them l cap versus e . So, this is equation number 5 and this is our equation number 6. So, plotting equations 5 and 6 so, e is greater than 1 minus l , here we can see that when l equal to 0 , e equal to 1 for the equality sign. So, this will come like this and the here the slope is negative. So, this curve will appear like this and so, this is curve belongs to l cap and this curve will become then equal to l cap minus 1 . And the common area, this area then where the eccentricity can be chosen for the transfer orbit and this is the point of minimum eccentricity. So, this is e_{min} .

(Refer Slide Time: 26:28)

Handwritten slide content:

$e = 1 - \frac{1}{n} = \frac{1}{l} - 1$ [from Eq. (5) & (6)]

$\Rightarrow a = \frac{1}{l} + \frac{1}{n} = \left(\frac{1+n}{n}\right) \frac{1}{l}$

$\frac{1}{l} = \frac{2n}{1+n}$

$\Rightarrow e = \frac{2n}{1+n} - 1 = \frac{n-1}{n+1} > 0 \quad [\because n > 0]$

$= \frac{r_f - r_i}{r_f + r_i}$

So; obviously, these are the intersection of this two equations. So, e minimum is given by intersection of this two equation therefore, we write e equal to one minus 1 cap by n equal to 1 cap minus n , this is from equation 5 and 6 . And this is greater than 0 because n is greater than 0. So, n is, we have written r_f by r_i .

(Refer Slide Time: 27:50)

So, proceeding in the same way, we can show that, as earlier we have shown, that this is the minimum eccentricity transfer orbit. So, this is the transfer orbit and this is our r_i and this is r_f . So, from the inner orbit if the satellite is sent into the outer circular orbit, so, this has to be done along this orbit. So, proceed in the same way as we have earlier done, there is nothing new in this. So, here in this case r_{perigee} will be equal to r_i and r_{apogee} will be equal to r_f . And ultimately you will get the same equation: e equal to r_f minus r_i divided by r_f plus r_i . So, once we have finished, that how the satellite will be transferred from one orbit to the another orbit, now we can find out what will be the energy required to transfer from one orbit to another orbit. So, if this is a natural sequence that should be followed. So, first we decide along which orbit, then how much energy is required, and from the energy required we can find out how much fuel is required for that particular transfer. So, going into the next stage.

(Refer Slide Time: 29:41)

So, transfer between circular coplanar orbits: So, what is our ultimate objective is to point, how much fuel is required. How much fuel, in this case we write this as propellant, how much find out how much propellant is required. So, we start with two circular orbits and now we know that this is the minimum eccentricity transfer.

We are not still proved that minimum eccentricity transfer will give consume minimum energy, or the some other eccentricity transfer will consume minimum energy. Those things are matter of discussion, which will go into in details later on. But right now we concentrate that once the minimum eccentricity transfer is fixed, then how much energy is required to go from point A to point B. Not only going from point A to B, but from the in inner orbit, which whose radius is r_i to the final orbit, whose radius is r_f . So, in the inner orbit we can write E_{initial} is equal to μ minus μ by $2r_i$, these things we have already worked out, because this orbit is circular, so, these m_i major axis in this case refers to the radius of this circle. So, this is our equation number 7. Similarly we can write E_{final} is equal to minus μ by $2r_f$. So, this is the total energy in of the satellite in the initial orbit here, and this is the total energy of the satellite in the final orbit. So, the change in energy that takes place, that will be given by E_f minus E_i and E_f is minus μ by $2r_f$. So, this becomes, taking μ outside and 2 outside, we can write this as 1 by r_i minus 1 by r_f ; this is ΔE . This is equation number 9. From here you can see that, because r_i is less than r_f therefore, this quantity in the bracket is positive.

So, this implies, that, there is positive change in the energy, and that energy is supplied by giving the impulse. So, if that is telling that the increasing the kinetic energy of the satellite. And also, as the satellite moves from this orbit to this orbit, the potential energy also goes up, because, the potential energy we are writing as minus mu by r per unit. This is the energy per unit mass. So, as the r increases, so, becomes this becomes less negative, therefore, it implies, that the potential energy is increasing. For the smaller orbit, this is more negative, means the potential energy is less.

(Refer Slide Time: 34:14)

Handwritten derivation on a blue background:

$$\Delta E_A = E_t - E_i \quad \left[\begin{array}{l} \text{change in Energy at A} \\ E_t \rightarrow \text{Energy in transfer orbit} \end{array} \right]$$

$$E_t = \frac{1}{2} v^2 - \frac{\mu}{r_t} = -\frac{\mu}{2a_t}$$

$$\Rightarrow a_t = \frac{r_i + r_f}{2}$$

$$E_t = -\frac{\mu}{2 \left(\frac{r_i + r_f}{2} \right)} = -\frac{\mu}{r_i + r_f}$$

$$\Rightarrow \Delta E_A = -\frac{\mu}{r_i + r_f} - \left(-\frac{\mu}{2r_i} \right)$$

$$= \Rightarrow \frac{\mu}{2r_i} - \frac{\mu}{r_i + r_f} = \mu \left[\frac{r_i + r_f - 2r_i}{2r_i(r_i + r_f)} \right] = \frac{r_f - r_i}{2(r_i + r_f)}$$

Therefore, we have delta EA will be equal to E transfer orbit minus E i. So, this is the change in energy at A. And E t is the energy in the transfer orbit. Now E t can be written as $\frac{1}{2} v^2 - \frac{\mu}{r}$, is equal to $-\frac{\mu}{2a}$, and here r of course, we know that that point A the r is nothing, but equal to r_i . And more over, we know that a t equal to the transfer orbit, now this will be r_i plus r_f by two, the semi major axis. So, therefore, E t becomes $-\frac{\mu}{2}$, minus $\frac{\mu}{r_i + r_f}$. Therefore, delta E a, this will be given as E t equal to $-\frac{\mu}{r_i + r_f}$ minus E i, now E i we know that this is equal to $-\frac{\mu}{2r_i}$. So, the quantity that will result, this will be $\frac{\mu}{2r_i} - \frac{\mu}{r_i + r_f}$. This is $\frac{r_f - r_i}{2(r_i + r_f)}$.

(Refer Slide Time: 37:16)

22-17

© CET
I.I.T. KGP

$$\Delta E_A = \frac{\mu(r_f - r_i)}{2r_i(r_i + r_f)} \quad \text{--- (10) } \checkmark$$

Similarly, we can write

$$\begin{aligned} \Delta E_B &= E_f - E_t = -\frac{\mu}{2r_f} - \left(-\frac{\mu}{r_i + r_f} \right) \\ &= \frac{\mu}{r_i + r_f} - \frac{\mu}{2r_f} = \mu \left[\frac{2r_f - r_i - r_f}{2r_f(r_i + r_f)} \right] \end{aligned}$$

$$\Delta E_B = \frac{\mu(r_f - r_i)}{2r_f(r_i + r_f)}$$

NPTEL

So, what we have got now ΔE_A is equal to $r_f \mu$ times, then μ is missing here and this is μ times r_f minus r_i divided by $2 r_i$ times r_f plus r_i . This is our equation number 10. Similarly we can write ΔE_B , the change in energy at B, this will be E_f minus E_t . So, E_f is nothing, but minus μ by $2 r_f$ and then minus E_t is nothing, but 1 by, now in that E_t is the energy in that transfer orbit. So, the total energy remains constant. So, wherever the particle be; wherever the satellite be in this orbit, either be satellite here, or either here, in this place the total energy does not vary. Kinetic energy will vary, potential energy will vary, but total energy will remain constant. Therefore, this can be written as minus μ by now the semi major axis, two times the semi major axis will be the total length. The semi major axis means the distance between A and B divided by 2. So, the two times the semi major axis will be distance A B, which is nothing, but r_i plus r_f by 2. So, r_i plus r_f this is r_i plus r_f .

So, therefore, this becomes and this can be written as μ times $2 r_f$ minus r_i minus r_f divided by 2 times r_f times r_i plus r_f . So, the previous equation we have equation number 10 here and this we term as equation number 11. So, whatever the energy has being the energy change takes place at A and B. So, these are imparted by giving the impulse. So, from here the impulse arises, it impulse arises from firing of the rockets. So, as we fire the rocket, so, if it burns the mass, and by burning the mass the consequent change in the velocity takes place. So, next we are going to compute this.

(Refer Slide Time: 40:55)

The Energy change are due to K.E imparted.

$v_{ic} \rightarrow$ velocity in initial circular orbit

$\Delta v_i \rightarrow$ change in velocity at point A

Equating Equation (12) and Eq. (10)

$$\Delta E_A = \frac{\mu(r_f - r_i)}{2r_i(r_f + r_i)} = \frac{1}{2}(v_{ic} + \Delta v_i)^2 - \frac{1}{2}v_{ic}^2$$

So, we have the energy change are due to kinetic energy imparted. So, we write $\Delta E_A = \frac{1}{2} v_{ic}^2 + \Delta v_i^2 + 2 v_{ic} \Delta v_i$, here v_{ic} is the velocity in initial circular orbit and Δv_i is the impulse imparted or the change in velocity at point A. So, ΔE_B now this is our equation number 12. Similarly we can write ΔE_B equal to $\frac{1}{2} v_{fc}^2 - \frac{1}{2} (v_{fc} - \Delta v_f)^2$. We are writing in terms of the final orbit velocity in the final orbits therefore, we are subtracting here Δv_f . So, so if how much the velocity is lacking over the final orbits final circular orbit velocity.

So, this is indicated by this and therefore, this minus sign appears here. Now equating equation 12 and equation 10. So, both are connected to the change in the energy. So, therefore, we have ΔE_A equal to $\mu(r_f - r_i)$, this will be equal to the quantity we have written here... So, simplifying this equation.

(Refer Slide Time: 44:11)

$$\frac{1}{2} v_i^2 + v_i \Delta v_i + \frac{1}{2} \Delta v_i^2 - \frac{1}{2} v_i^2$$

$$= \frac{\mu (r_f/r_i - 1)}{2 r_i (r_f/r_i - 1)} = \frac{\mu}{2 r_i} \left(\frac{n-1}{n+1} \right)$$

$$\Rightarrow \Delta v_i^2 + 2 v_i \Delta v_i = \frac{\mu}{r_i} \left(\frac{n-1}{n+1} \right)$$

$$\boxed{\frac{\mu}{r_i} = v_{ic}^2} \quad \text{quadratic Eq.}$$

So, this gives us $\frac{1}{2} v_i^2 + v_i \Delta v_i + \frac{1}{2} \Delta v_i^2 - \frac{1}{2} v_i^2$, this is equal to $\frac{\mu}{2 r_i} \left(\frac{n-1}{n+1} \right)$. So, if either we can proceed in the same way r_f minus r_i , or we can change it to when dividing r_f by r_i .

So, for simplicity we can fix this as r_f by r_i minus 1 divided by 2 r_i times ... is equal to $\frac{\mu}{2 r_i} \left(\frac{n-1}{n+1} \right)$. So, this this cancels out and we are left with $\Delta v_i^2 + 2 v_i \Delta v_i = \frac{\mu}{r_i} \left(\frac{n-1}{n+1} \right)$. Now we know that $\frac{\mu}{r_i}$, now this $\frac{\mu}{r_i}$, this is nothing, but velocity square in the initial orbit, so, this is v_{ic}^2 . Now that the what we have got, this is a quadratic equation, which can be solved for Δv_i , and this Δv_i will give the change in the velocity that has to be imparted at the point A.

(Refer Slide Time: 47:11)

$$\Delta v_i^2 + 2v_i c \Delta v_i - v_i^2 \left(\frac{n-1}{n+1} \right) = 0$$

$$\Delta v_i = \frac{-2v_i c \pm \sqrt{4v_i^2 c^2 + 4v_i^2 \left(\frac{n-1}{n+1} \right)}}{2}$$

$$= -v_i c \pm v_i c \sqrt{1 + \frac{n-1}{n+1}}$$

$$= v_i c \left[-1 \pm \sqrt{\frac{n+1+n-1}{n+1}} \right] = v_i c \left[-1 \pm \sqrt{\frac{2n}{n+1}} \right]$$

$$\Delta v_i = v_i c \left[1 \pm \sqrt{\frac{2n}{n+1}} \right]$$

So, from here we can write, delta v i equal to, one more step we can go, delta v i square plus 2 v i c and delta v i minus v i c square n minus 1 by n plus 1 equal to 0. So, find out the value of delta v i. So, delta v i will be minus 2 v i c plus minus... 2 times v i c square times n minus 1 by n plus 1 divided by 2.... v i c can be taken out of the root sign. So, if this is minus 4 4a c. So, this quantity will be 4 here in this place. This is 1 plus n minus 1 by n plus 1 under root. v i c times, now v i c we can take it outside,... 1 minus plus minus n plus 1 plus n minus 1 divided by n plus 1..... minus 1 plus minus 2 n divided by n plus 1 under root.

So, what we got is delta v i is equal to v i c times minus one plus minus two n under root divided by n plus 1 under root. And here minus sign is just missing out. So, naturally if you look into this equation.

(Refer Slide Time: 49:49)

$$\Delta v_i = v_{ic} \left[-1 \pm \sqrt{\frac{2n}{n+1}} \right] \quad \text{--- (14)}$$

$$\Delta v_i = v_{ic} \left[\sqrt{\frac{2n}{n+1}} - 1 \right] \quad \text{--- (15)}$$

change in velocity (A) (required)

Similarly we can find the change in velocity required at point (B).

So, finally, we can write here this is our Δv_i equal to v_{ic} minus 1 plus minus $2n$ divided by $n+1$ under root, and this we term as equation number 14. Now we can look in this place, the minus sign is not allowed because, in the elliptic orbit we have velocity higher than the circular orbit and therefore, the positive impulse must be given, that is the increase in velocity should takes place.

So, Δv_i will be given as v_{ic} times $2n$ divided by $n+1$ under root minus 1. So, this is equation number 15. So, this is the change in velocity at A which is required. So, similarly we can find the change in velocity required at point B. So, for that we need to solve equation 13 and 10, 13 and 11. So, these are the equations this is the equation 11 which describes ΔE_B and equation 13 also this describes ΔE_B . So, we equate these two equations. Equating equations 13 and 11.

Equating Eq. (13) & (11)

$$\Delta E_B = \frac{\mu(r_f - r_i)}{2r_f(r_i + r_f)} = \frac{1}{2}v_f^2 - \frac{1}{2}v_c^2 + v_{fc}\Delta v_f - \frac{1}{2}\Delta v_f^2$$

Velocity in final circular orbit

$$\Rightarrow \frac{\mu(n-1)}{2r_f(n+1)} = v_f\Delta v_f - \frac{1}{2}\Delta v_f^2$$

$$\Rightarrow \Delta v_f^2 - 2v_f\Delta v_f + v_f^2\left(\frac{n-1}{n+1}\right) = 0$$

So, ΔE_B equal to μ times r_f minus r_i ... So, this this cancels out and here, so, this implies μ times r_f by r_i , we have written as n , this is n minus 1 divided by $2r_f$ and here r_f by r_i , again this can be written as n plus 1. So, this is equal to v_f times Δv_f and minus 1 by 2 Δv_f square. This implies Δv_f square minus 2 times v_f Δv_f plus v_f square times n minus 1 divided by n plus 1 equal to 0 . So, here v_f we have replaced as v_f square equal to μ by r_f because this is the v_f is the velocity in circular orbit, in final circular orbit.

$$\Delta v_f = v_f \left[1 - \sqrt{\frac{2}{1+n}} \right] \quad \text{--- (16)}$$

$$\Delta v_f = \frac{2v_f \pm \sqrt{4v_f^2 - 4v_f^2\left(\frac{n-1}{n+1}\right)}}{2}$$

$$= v_f \pm v_f \sqrt{\frac{n+1 - n+1}{n+1}}$$

$$\Rightarrow v_f \left[1 \pm \sqrt{\frac{2}{n+1}} \right] \checkmark$$

NPTEL

So, after we get into again we are getting a quadratic equation and this quadratic equation can be solved to give Δv_f equal to $v_{f, \text{final}}$... So, this is our equation number 16. So, how much is the impulse required at point A and how much is the impulse required at point B is given by this equation number 15 and equation number 16. So, at least we can do the solution of Δv_f here, and this will be $2 v_f$ plus minus $4 v_f^2$ minus $4 v_f^2$ times $n - 1$ by $n + 1$ divided by 2... So, we are getting this equation. So, equation has been obtained from this equation. So, we continue to discuss in the next lecture.

Thank you very much.
