Trajectory Transfer (Contd.)

Because, last time we had started with general to impulse transfer as part of trajectory transfer, so we continue with that.

(Refer Slide Time: 00:28)

So, we took the case, where we had the inner orbit, whose radius is given by r_i , and the final orbit was radius is r_f , and a satellite is moving in the inner radius orbit, and it has to be transferred into the outer radius orbit, but not along the tangential path means, we are not starting here in this point and then starting tangentially here in this point and going up to this point, rather at intermediate point anywhere we are passing from point a to point b. So, this is not Hohmann transfer what we have been discussing. So, for this kind of treatment, we need to generalized further how to find out the delta v required here in this place, and the delta v required here in this place. So, for that v_{ic} here is given, which is the speed in the, or the velocity in the circular orbit, and similarly for the

velocity in the outer orbit is also known to us, which is $v_f c$, so this is the velocity in the outer orbit.

So, if v_{ie} is the velocity in the electrical orbit, in which the satellite is to be put for the transfer purpose, and from there the orbit will be thrown into the, it will put into the final circular orbit. So, for sending it along this direction, so we need a velocity which is given by v_{ie} . Now, v_{ie} is the velocity required velocity, so how much change in velocity is given, how much change in velocity is required that is given by Δv_i , so we are started working with this. So, we have the velocity in the inner circular orbit, which is given by μ / r_i , v_{ie} is the velocity in the electric orbit at point A will consider, and again at point B also will consider. So, we can put here subscript later on, but v_{ie} indicates the velocity in the electric orbit, and we can put subscript here to indicate that this is at point A, and v_{fc} is the velocity in the electric orbit at B.

So v_{fe} , and here we have put the final, to indicate this is corresponding to this point, otherwise the same thing could have been indicated by. So, we can take it like $v_{eccentric}$, $v_{electrical A}$ and $v_{electrical B}$ we can write, but here we have written v_f means, this is the initial point here a starting point in the initial orbit, and this is the point in the final orbit. So, corresponding to that, this subscribe i and f they are appearing. And e is corresponding to the electrical orbit, and finally we can put a subscript here B to indicate that this is at point B. So, that completes our notation, and the v_{fc} , this is the velocity in the final circular orbit. c is stands for the circular orbit, which is given by μ / r_f , velocity in the circular orbit at B.

$$\Delta \vec{v} = \frac{v}{v_{ic}}$$

$$\Rightarrow \hat{v}_{ic} = \frac{v_{ic}}{v_{ic}} = 1 \checkmark \quad \text{--- (A)}$$

Similarly

$$\hat{v}_{fc} = \frac{v_{fc}}{v_{ic}} = \frac{\sqrt{\mu/r_f}}{\sqrt{\mu/r_i}} = \sqrt{\frac{r_i}{r_f}} = \frac{1}{\sqrt{n}} \checkmark$$

--- (B)

$$\vec{\Delta v_i} = \vec{v_{ie}} - \vec{v_{icA}}$$

$$\Delta v_i^2 = v_{ie}^2 + v_{ic}^2 - 2 v_{ie} v_{ic} \cos \alpha_i \quad \text{--- (C)}$$

NPTEL

So, after completing this, we assumed the quantities like v_{ic} is equal to v by v_{ic} , where v_{ic} is the velocity in the initial circular orbit. So, this implies v_{ic} by v_{ic} is equal to 1, and similarly v_{fc} will be v_{fc} by v_{ic} , so this is $1/\sqrt{n}$. Now, therefore Δv_i this can be calculated, so how much this Δv_i is, that can be calculated. From here Δv_i is equal to v_{ie} minus v_{ic} , so this is the velocity in the elliptic orbit at A, and velocity in the circular orbit at A. and this quantity in the vector notation can be written like this.

(Refer Slide Time: 05:01)

(23-18)

© CEE
I.I.T. KGP

Similarly we can write

$$\vec{\Delta v_f} = \vec{v_{fe}} - \vec{v_{fcB}}$$

$$\Rightarrow \Delta v_f^2 = v_{fe}^2 + v_{fc}^2 - 2 v_{fe} v_{fc} \cos \alpha_f \quad \text{--- (D)}$$

NPTEL

Similarly, we have written last time, that Δv_f is equal to v_{fc} , which is the velocity in the final circular orbit minus v_{fe} . So, for that we have the case here. This is the velocity in the circular orbit, we put here v_{fc} , and this is the velocity in the electrical orbit, which is shown by here the blue color arrow, so this is v_{fe} , and these are at point B, so we can put a subscript here B. So, we can insert subscript here B, to indicate that this is the velocity in the circular angle electric orbit at B. therefore, Δv_f this will be given by this particular equation. So, we worked out to this extended last time.

(Refer Slide Time: 05:57)

General two impulse transfer.

$$\Delta v_i^2 = v_{ie}^2 + v_{ic}^2 - 2 v_{ie} v_{ic} \cos \alpha_i \quad \text{--- (1)}$$

$$\Delta v_f^2 = v_{fe}^2 + v_{fc}^2 - 2 v_{fe} v_{fc} \cos \alpha_f \quad \text{--- (2)}$$

$$v = \sqrt{\mu \left(\frac{2}{r} - \frac{1}{a} \right)}$$

$a \rightarrow$ semi major axis of the ellipse.

Now, we are start working further, so what we have got Δv_i square, this equal to v_{ie} square, plus v_{ic} square minus 2 v_{ie} and v_{ic} to $\cos \alpha_i$. This is equation 1, and the equation 2 is Δv_f square, this is equal to. So, here the notation A and B they are not appearing, so if you want we can put here as A, and here we can put as B, but it is convenient to drop this subscript, because we convert this i with initial and f with the final, so automatically this will give you the meaningful expression. So, further while carrying out the work, so we are going to drop this subscript A and subscript B. Now, we know that v in a electrical orbit it is given by μ times, 2 by r minus 1 by a under root. So, here a is the semi major axis of the ellipse.

(Refer Slide Time: 08:02)

Handwritten derivation on a blue grid background:

$$\begin{aligned}
 v_{ie}^2 &= \mu \left(\frac{2}{r_i} - \frac{1}{a} \right) \\
 &= \mu \left(\frac{2}{r_i} - \frac{1-e^2}{l} \right) \\
 &= \frac{\mu}{r_i} \left[2 - \frac{1-e^2}{l/r_i} \right] = v_{ic}^2 \left[2 - \frac{1-e^2}{\frac{l}{r_i}} \right]
 \end{aligned}$$

When $\frac{l}{r_i} = 1$

$$\frac{v_{ie}}{v_{ic}} = \frac{1}{v_{ic}} \Rightarrow \frac{v_{ie}^2}{v_{ic}^2} = \left(\frac{v_{ie}}{v_{ic}} \right)^2 = 2 - \frac{1-e^2}{1} \quad (3)$$

Additional notes on the slide:

- Top right: (24.2) and a logo for CEE IIT KGP.
- Right side: $l = \text{semi latus rectum} = a(1-e^2)$
- Bottom left: A logo for NPTEL.

So therefore, we will have now v_{ie} , so we are dropping the subscript A. So, v_{ie} can be written as v_{ie} mu square is equal to mu times 2 by r_i minus 1 by a . Now a , we can express as, or other say l we can write as, which is the semi latus rectum. This is equal to a times $1 - e^2$. So, we can put here, insert here in this place, 2 by r_i and a will be, l by $1 - e^2$. r_i we can take it outside, and we can express it like this. So, mu by r_i is nothing, but v_{ic} , which is the velocity in the circular orbit square. So, this become minus 2 times, 2 minus 1 minus e^2 , and l by r_i we write as l cap, so here l by r_i this is equal to l cap. So, we have got very simple expression for v_{ie} , written in term of v_{ic} . So, going further into it is, now v_{ie} divided by v_{ic} , this can be written as v_{ie} cap. According to our notation that we have developed earlier, so this become sv_{ie} cap square, this will be equal to, this from here we can find it out. So, just we have to divided both side by v_{ic} square, so we get this quantitative here. This is our expression number 3.

(Refer Slide Time: 11:17)

24-3

Similarly at Point B in the outer orbit

$$\begin{aligned}
 v_{fe}^2 &= \mu \left(\frac{2}{r_f} - \frac{1}{a} \right) = \mu \left[\frac{2}{r_f} - \frac{1-e^2}{l} \right] \\
 &= \frac{\mu}{r_i} \left[\frac{2r_i}{r_f} - \frac{(1-e^2)r_i}{l} \right] \\
 &= v_{ic}^2 \left[\frac{2}{r_f/r_i} - \frac{1-e^2}{l/r_i} \right] = v_{ic}^2 \left[\frac{2}{n} - \frac{1-e^2}{\hat{r}} \right] \\
 \frac{v_{fe}^2}{v_{ic}^2} &= \frac{2}{n} - \frac{1-e^2}{\hat{r}}
 \end{aligned}$$

$r_f/r_i = n$

NPTEL

Similarly, at point B in the outer orbit, we can write v_{fe}^2 , this is equal to μ times $2/r_f$ minus $1/a$, where a is the semi major axis of the transfer orbit, which is the electrical orbit. Therefore, this is $2/r_f$ minus $1 - e^2$ by l . And we can take it out, r_i we can take as a common, so this can be then expressed as $2/r_i$ divided by r_f/r_i minus. Now, we have the known quantities here, so μ/r_i is nothing, but v_{ic}^2 square, and this we can write as $2/r_f$ by r_i minus $1 - e^2$ by l by r_i , this is v_{ic}^2 square. Hence, $2/r_f$ by r_i is nothing, but n . You get from the beginning we have been assuming this quantity. So, this is $2/n$ minus $1 - e^2$ by $\hat{r}$. So, thus what we get here v_{fe}^2 divide by v_{ic}^2 square, this is going to $2/n$ minus $1 - e^2$ by $\hat{r}$.

(Refer Slide Time: 13:43)

So, from here we can write following the earlier notations, so v_{fe} by v_{ic} , this is nothing, but v_{fe} cap. This is the notation that we will follow, and therefore v_{fe} square v_{fe} cap square, this becomes equal to 2 by n minus 1 minus e square by l cap. This is our equation number 4. Now, going back into our old figure, so here if you look into this figure, so what are the quantities to be found further is, this α_i , which is the angle from here to here, this is angle α_i , α_i , and the angle between this and this α_f , so this two need to be worked out. Now, say this is our transfer trajectory, this is v_{θ} , and here we can show this as v_r , this is the velocity vector v .

So, we will do in new figure for this, this figure is blurred. v_{θ} is perpendicular to the radius vector, this is the radius vector here. And suppose from the velocity will be tangential to the trajectory, so velocity can be shown along this direction as v , and this is v_{θ} . So if you look into this, the flight path angle is defined as the angle between the local horizontal. So, in case of this trajectory transfer, or the any particle moving in a gravity field, so this particular angle we can write here as α and this is call the flight path angle. So, α is flight path angle, and v_r will be just in the radial direction, so if this is the direction of r , so here we will have v_r in this direction. So, we have v_{θ} here, v here and v_r along this direction. So, resultant of this two will be the velocity vector v .

(Refer Slide Time: 17:44)

So, what we have done here, say this is the velocity vector, and this is v and this is our θ , and this is our v_r . So, where v is the resultant of v_r and v_θ . And the angle from here to here, this we have shown as angle α , which is the flight path angle. So, taking the same in the perspective of shape around the earth, this is the earth, in some orbit. Here we are showing this as a circular orbit, but suppose this little bit electrical, so we have this angle as θ . So, we are measuring the true anomaly from this place, and then v_θ will be perpendicular to this radius vector r . So, v_θ will be along this direction, and suppose this is electrical. Then v direction will be tended to the path, so let us make it little bit electrical, so that we can show here, v and this is not v_r . So, this depicts the real picture in the case our, may be any heavenly body. In this case we are taking this as the earth, and around that in a circular, in a electrical orbit or in any trajectory, some particle is moving under gravity.

So, this is the real situation, which is shown here. So, this is our v vector and this is the resultant vector, so v_θ and v_r . So, we are taking a in a proper way v , v_θ and this is v_r . And, the flight path angle obviously, we have told that in that case this will be indicated by the angle from here to here, which is nothing, but α . So, whatever we have shown here this is a generalized representation. With this representation what we want to work out, what will be the value of $\tan \alpha$, and then if you find out $\tan \alpha$, so from here we will be able to find out the value of $\cos \alpha$. So, this is the generalized representation, and the representation that we follow here. This is for our gravitational

case. So, this angle obviously we have written as alpha, so we can write tan alpha, this equal to v_r by v_θ , and v_r is nothing, but $r \dot{\theta}$. And v_θ is nothing, but $r \dot{\theta}$. Therefore, this becomes $\frac{dr}{dt}$ into $\frac{1}{r \dot{\theta}}$. Write it in this way, so this becomes $\frac{1}{r} \frac{dr}{d\theta}$.

(Refer Slide Time: 21:47)

Handwritten derivation on a blue background:

$$\tan \alpha = \frac{1}{r} \frac{dr}{d\theta}$$

$$\frac{l}{r} = 1 + e \cos \theta$$

$$-\frac{l}{r^2} \cdot \frac{dr}{d\theta} = -e \sin \theta$$

$$\Rightarrow \frac{1}{r} \frac{dr}{d\theta} = \frac{r e \sin \theta}{l}$$

$$\Rightarrow \tan \alpha_i = \frac{1}{r_i} \frac{dr_i}{d\theta_i} = \frac{r_i e \sin \theta_i}{l} = \frac{e \sin \theta_i}{\alpha}$$

Final result boxed: $\tan \alpha_i = \frac{e \sin \theta_i}{\alpha}$ (Equation 5)

So, now given tan alpha is equal to $\frac{1}{r} \frac{dr}{d\theta}$. We can utilize the relationship for the ellipse developed earlier, which is $\frac{l}{r} = 1 + e \cos \theta$, to work out the value of tan alpha. So, from here we can find out the value of $\frac{dr}{d\theta}$. So, differentiating this, this gives us $-\frac{l}{r^2} \frac{dr}{d\theta} = -e \sin \theta$. So, thus we will have $\frac{1}{r} \frac{dr}{d\theta}$, because what we need is $\frac{1}{r} \frac{dr}{d\theta}$, so we put on the left hand side $\frac{1}{r} \frac{dr}{d\theta}$, and l and r we can tip on the right hand side, so we will have r times $e \sin \theta$ divided by l . So, this implies tan alpha, this will be nothing, but $\frac{1}{r} \frac{dr}{d\theta}$, equal to $\frac{r e \sin \theta}{l}$. And we will put a subscript i to indicate that true anomaly, at the initial point, θ_i . And l divided by r_i , this will become α . So, thus tan alpha i is equal to $e \sin \theta_i$ divided by α . This is our equation number five.

(Refer Slide Time: 24:14)

24-7.

$$\tan \alpha_f = \frac{1}{r_f} \frac{dr}{d\theta} = \frac{r_f e \sin \theta_f}{l} = \frac{r_f / r_i e \sin \theta_f}{l / r_i}$$

$$= \frac{n}{l} e \sin \theta_f$$

$\tan \alpha_f = \frac{n}{l} e \sin \theta_f$

→ (5)

Similarly, we can work out for the tan alpha i, so again we will have for tan alpha i is equal to 1 by r i times, d r by d theta. This we will be nothing, but r i times e sin theta i divided by l. this we can express as r f by r i, l by r i, and r f by r i nothing, but n, and l by r i is nothing, but l cap, and this is e sin theta f. And this tan alpha f, this becomes equal to n by l cap. This is our equation number 6. Once we have got this, so from here now it is easy to work out. Now, the quantity which is present there, which is theta f and theta i, this two also need to be eliminated.

(Refer Slide Time: 25:52)

24-8.

Now θ_i and θ_f in equations (5) and (6) need to be eliminated.

$$\frac{l}{r_i} = 1 + e \cos \theta_i \Rightarrow \frac{l}{r_i} = 1 + e \cos \theta_i$$

$$\Rightarrow e \cos \theta_i = \frac{l}{r_i} - 1$$

$$\Rightarrow \cos \theta_i = \frac{\frac{l}{r_i} - 1}{e}$$

$$\Rightarrow \sin \theta_i = \sqrt{1 - \cos^2 \theta_i}$$

$\sin \theta_i = \sqrt{1 - \frac{(\frac{l}{r_i} - 1)^2}{e^2}}$

→ (7)

Now, θ_i and θ_f in equations five and six, need to be eliminated, and this we can do using the original equation which is given to us, which is l/r is equal to $1/e \cos \theta$. So from here we can replace θ in terms of l and r and e . So, this implies, now l/r_i , so if we take here as θ_i , so we will have l/r is equal to $1/e \cos \theta_i$. So, this implies l cap equal to $1/e \cos \theta_i$, and from here we get l cap minus $1/e \cos \theta_i$, and this implies. So, this is our $\sin \theta_i$.

(Refer Slide Time: 28:04)

Similarly,

$$\frac{1}{r_f} = \frac{1}{e \cos \theta_f} \Rightarrow \frac{l/r_i}{r_f/r_i} = \frac{1}{e \cos \theta_f}$$

$$\Rightarrow \frac{l}{n} = \frac{1}{e \cos \theta_f}$$

$$\Rightarrow \cos \theta_f = \frac{1}{e} \left(\frac{l}{n} - 1 \right)$$

$$\Rightarrow \sin \theta_f = \sqrt{1 - \frac{1}{e^2} \left(\frac{l}{n} - 1 \right)^2} \quad \text{--- (8)}$$

Similarly, we will have l/r_f is equal to $1/e \cos \theta_f$, so this implies l/r_i divided by r_f/r_i , plus $e \cos \theta_f$, and this implies l cap by n is equal to $1/e \cos \theta_f$. and, this implies $\cos \theta_f$ is equal to l cap divided by n minus $1/e$ and shown by. And, therefore $\sin \theta_f$ then becomes $1 - 1/e^2 \times l$ cap n divided by n minus 1 whole square under root. This is our equation number eight.

(Refer Slide Time: 29:23)

$$\tan \alpha_i = \frac{e \sin \theta_i}{l_i} = \frac{e}{l_i} \times \sqrt{1 - \frac{(l_i - 1)^2}{e^2}}$$

$$\tan \alpha_i = \frac{1}{l_i} \sqrt{e^2 - (l_i - 1)^2}$$

$$\Rightarrow \cos \alpha_i = \frac{1}{\sqrt{1 + \tan^2 \alpha_i}} = \frac{l_i}{\sqrt{e^2 + 2 l_i - 1}}$$

$$\tan \alpha_f = \frac{n}{l_i} e \sin \theta_f = \frac{n}{l_i} e \cdot \sqrt{1 - \frac{1}{e^2} \left(\frac{l_i}{n} - 1 \right)^2}$$

Once we have got this, now we can write an alpha i equal to e sin theta i by l cap, so this will be e by l cap, and sin theta is our 1 minus l cap minus 1 whole square, divided by e square under root, so taking e inside. So, this implies cos alpha i equal to, and if you do the processing, you can prove that this quantity will be equal to, by inserting this quantity here in this place. This will turn out to be 1 by l cap divided by e square plus 2 l cap minus 1 under root. Similarly, you have tan alpha, tan alpha f equal to n by l cap, e sin theta f, and the sin theta f just now we have worked out. So the sin theta value is given here, so we can insert here in this place, this l cap time e sin theta f, 1 minus 1 by e square, and if you simplify it.

(Refer Slide Time: 32:10)

$$\cos \alpha_f = \frac{1}{\sqrt{1 + \tan^2 \alpha_f}} = \frac{l}{\sqrt{2 l^2 n + (e^2 - 1) n^2}}$$

$$\Delta v_i^2 = v_{ie}^2 + v_{ic}^2 - 2 v_{ie} v_{ic} \cdot \frac{l}{\sqrt{e^2 + 2 l^2 - 1}} \quad \checkmark$$

$$\Delta v_f^2 = v_{fe}^2 + v_{fc}^2 - 2 v_{fe} v_{fc} \cdot \frac{l}{\sqrt{2 l^2 n + (e^2 - 1) n^2}}$$

$$\left(\frac{\Delta v_i}{v_{ic}} \right)^2 = 1 + \left(\frac{v_{ie}}{v_{ic}} \right)^2 - 2 \left(\frac{v_{ie}}{v_{ic}} \right) \cdot \frac{l}{\sqrt{e^2 + 2 l^2 - 1}}$$

So, from here we can find out cos alpha f, inserting this values and simplifying it, finally you will get l cap, divided by 2. So, we have got finally, the alpha e and alpha f, so our job is done, and therefore delta v i, this can be written as v i e square plus v i c square, minus 2 v i e times to v i c. This is the equation that we wrote, so these are the two equations. So, insert the value of the cos alpha i and cos alpha f in this two equation; equation 1 and 2, so after inserting the value. So, these are the two equations which are available to us, and this two will give us the amount of impulse required, but we need to further simplify these two equations. So, the notation that we have developed earlier, that if we divide the whole thing by v i c in this equation, so delta v i square this can be written as delta v i by v i c square, and v i c divided by v i c, this will become 1. So this particular thing we will write here as 1, and plus v i e by v i c square minus, and here v i c, v i c cancels out and we get v i e by v i c, times l cap by e square plus 2 l cap minus 1 under root.

(Refer Slide Time: 35:45)

(24-11)

$$\Rightarrow \Delta v_{ic}^2 = 1 + \left(2 - \frac{1-e^2}{\lambda}\right) - 2 \times \sqrt{2 - \frac{1-e^2}{\lambda}} \times \frac{1}{\sqrt{e^2 + 2\lambda - 1}}$$

$$\Delta v_{ic}^2 = \sqrt{3 - \frac{1-e^2}{\lambda} - 2\lambda} \quad \text{--- (10)}$$

Similarly

$$\Delta v_f^2 = v_{fe}^2 + v_{fc}^2 - 2v_{fe}v_{fc}\cos\alpha_f$$

$$\frac{\Delta v_f^2}{v_{ic}^2} = \left(\frac{v_{fe}}{v_{ic}}\right)^2 + \left(\frac{v_{fc}}{v_{ic}}\right)^2 - 2\left(\frac{v_{fe}}{v_{ic}}\right)\left(\frac{v_{fc}}{v_{ic}}\right)\cos\alpha_f$$

So, this implies delta v i cap square equal to, do the simplification while putting the values of v i e by v i c, so this will be 1 plus v i e by v i c, earlier we have derived. this quantity is nothing, but 2 minus 1 minus e square l cap, so 2 times, this is 2 times, v i e by v i c is 2 times, 2 minus 1 minus e square by l cap, and this multiplied by l cap divided by e square plus 2 l cap minus 1 under root. And then simplifying this will give you 3 minus 1 e square. This is our equation number 10. Similarly, delta v f is our v f e square, plus v f c square minus 2 cos alpha f, dividing both side by v i c, v f e divided by v i c square, cos alpha f.

(Refer Slide Time: 38:25)

(24-12)

$$\Delta v_f^2 = \left(\frac{1}{\sqrt{n}}\right)^2 + \left(\frac{2}{n} - \frac{1-e^2}{\lambda}\right) - 2 \left(\sqrt{\frac{2}{n} - \frac{1-e^2}{\lambda}}\right) \left(\frac{1}{\sqrt{n}}\right)$$

$$\times \frac{1}{\sqrt{2\lambda n + (e^2 - 1)n}}$$

$$\Rightarrow \Delta v_f^2 = \sqrt{\frac{3}{n} - \frac{1-e^2}{\lambda} - \frac{2}{n} \sqrt{\frac{1}{n}}} \quad \text{--- (11)}$$

$v_{ic} \rightarrow$

So therefore, we can write as Δv_f^2 . Here we have taken the under root, so we remove the square term here, this is fine. So, Δv_f by v_i , this will be nothing, but Δv_f . So, Δv_f^2 , then this becomes. Now, we need to insert this values here v_f by v_i and v_e by v_i , and all this quantities we have developed earlier. So, v_f by v_i is nothing, but $1/n$. And v_e by v_i , this is nothing, but $2/n - 1$, then minus 2 times, and this is one quantity, another quantity we have $1/n$, $n \cos \alpha_e$, which is nothing, but $1/n$ divided by $2 - 1/n$, plus $c^2 - 1$. So, if we do the simplification what we get, Δv_f equal to $3/n - 1/e^2$, divided by $1/n - 2/n$, times $1/n$. And this is our equation number 11. So, these two equations give you the impulses, in terms of Δv_i and Δv_f at the point A and B. So, Δv_i is at the point A, and Δv_f this is at the point B. And this quantity is nothing, but if you multiply this quantity by Δv , this multiply this by v_i , so this gives you the actual amount of impulse. So, this equation looks very elegant, and this is simply to work with, and therefore this representation has been taken up.

(Refer Slide Time: 41:42)

So, this is the generalized transfer, and the generalized transfer just now we have worked, and the earlier the particular transfer for the, what we have turn as the Hohmann transfer which we have taken, in which we transfer from point A to point B, in an electrical orbit. This is minimum eccentric electrical orbit and we proved this also in the beginning of the trajectory transfer lecture. So, whatever we have worked out which is

representing the generalized transfer. So, from here this you can reduce to this particular case, because in this particular case alpha i and alpha f, both will be equal to 0. So for as Hohmann transfer alpha i equal to 0, and alpha f equal to 0. So, if we take these two, so it is easy to work out and what ultimately you get the same result, so those it is dwells we can show as.

(Refer Slide Time: 43:26)

The image shows a handwritten derivation on a blue grid background. At the top right, there is a circled number '24-14' and a small box containing '© CEE I.I.T. K'.

$$\left(\frac{\Delta v_i}{v_{ic}}\right)^2 = 1 + \left(\frac{v_{ie}}{v_{ic}}\right)^2 - 2\left(\frac{v_{ie}}{v_{ic}}\right) \times \left(\frac{v_{ic}}{v_{ic}}\right) \times \cos \alpha_i$$

Below this, there is a note: $\alpha_i = 0$ and $\cos \alpha_i = 1$.

$$= \left[\frac{v_{ie}}{v_{ic}} - 1 \right]^2$$

Finally, the result is boxed:

$$\Rightarrow \frac{\Delta v_i}{v_{ic}} = \frac{v_{ie}}{v_{ic}} - 1$$

An NPTEL logo is visible in the bottom left corner of the slide.

So, what you need to do for that, we had the equation where delta v i by v i c square, we wrote as 1 plus v i e by v i c square, minus 2 v i e by v i c, and v i c by v i c times cos alpha i. So the cos alpha i, once alpha i is equal to 0, so cos alpha i becomes equal to 1, and therefore what you get the remaining quantity which is present here. So, this can be written as 1 minus v i e by. This quantity becomes equal to 1, so this becomes v i e by v i c, we will write this as v i e by v i c minus 1 square. So, this implies v i delta v i by v i c, why we have written in this format, because v i e is greater than v i c. Therefore, it is appropriate represented like this. Similarly, you can work out for delta v f by v i c, and if you try to equate and you will see that the results are same, for both this case and in this case, there is no difference. So, this you can take up as an exercise, and we can go to the next topic.

So, once we have done this, now the obviously, while starting in the beginning we discuss that Hohmann transfer is the minimum eccentric transfer. But how efficient this is, that was not solved. So, that we can solve further, by taking what is called the bi-elliptic case. So, by bi-elliptic case, in that case we have one circular orbit like this, and another circular orbit like this, so instead of transferring from point A to point B here. The transfer starts like at point A, the impulse is given and it is, the satellite goes into an elliptical orbit, reaches from like this. So, this is point A and the point B is shown here in this point, and again at point B an impulse is given, so that the satellite comes and becomes tangential at this point, so at that point then, we give an impulse of Δv_C in the negative direction of course. So, this is the point C and that we will put it into the circular orbit. So, here the impulse required is Δv_A , and here the impulse required is Δv_B , and here a negative impulse is given, to put it in this circular orbit and this is the center.

So this is called Bielliptic transfer. So, Hohmann transfer this is not always cheaper, so as the radius, inner and the outer radius difference increases, so say this is the inner radius r_i here and r_f tends to infinity, so we keep on increasing the outer radius, and then we want to take the satellite from point A to point C in the outer circle. Then which one will be more effective; Hohmann transfer or Bielliptic transfer. So, the question here can be posed as given two orbits of radius r_i and r_f , where r_f is greater than r_i , then find out either Hohmann transfer will be more efficient or Bielliptic transfer

will be more efficient. So, before we go into the Bielliptic transfer, we need to work for the, how much energy is required in the Hohmann transfer, as we increase the radius of the circle r_f , and this we have done earlier also. If you remember in our lecture number three, in the lecture number 23. This was the, we have started from this point at point A and we give the impulse Δv_i and finally at point B, we give the impulse Δv_f , and this where the results obtained.

For Hohmann Transfer.

$$\Delta v_A = v_{ic} \left[\sqrt{\frac{2n}{n+1}} - 1 \right]$$

$$\Delta v_B = v_{fc} \left[1 - \sqrt{\frac{2}{n+1}} \right]$$

$$\Delta v_A + \Delta v_B = \sqrt{\frac{\mu}{r_i}} \left[\sqrt{\frac{2n}{n+1}} - 1 \right] + \sqrt{\frac{\mu}{r_f}} \left[1 - \sqrt{\frac{2}{n+1}} \right]$$

$$= v_{ic} \left[\left\{ \sqrt{\frac{2n}{n+1}} - 1 \right\} + \left\{ 1 - \sqrt{\frac{2}{n+1}} \right\} \frac{r_{fc}}{v_{ic}} \right]$$

So, we can utilize this result, so for Hohmann transfer, we can write here as Δv_A , this equal to v_{ic} times $2n$ by n plus 1 under root minus 1 , and Δv_B equal to v_{fc} 1 minus 2 by n plus 1 under the root. Starting with this 2 equations, therefore Δv_A plus Δv_B , so v_{ic} we can write as, μ by r_i under root. Similarly, v_{fc} we can write μ by r_f under root, times 1 minus 2 by n plus 1 under root. So, if we take μr_i outside means we are virtually taking v_{ic} outside, so if we take v_{ic} as the common, so what we get here. $2n$ by n plus 1 under root minus 1 , into v_{fc} by v_{ic} . Now, v_{fc} by v_{ic} can be written in terms of r_f and r_i .

Handwritten derivation on a blue background with NPTEL logo in the bottom left. The derivation shows the ratio of change in velocity to initial velocity for a particle in a circular orbit. It starts with the expression for the ratio of velocities, then uses the binomial expansion to find the change in velocity, and finally simplifies the expression to a form involving the ratio of radii.

$$\frac{v_{fc}}{v_{ic}} = \frac{\sqrt{\mu/r_{fc}}}{\sqrt{\mu/r_{ic}}} = \sqrt{\frac{r_{ic}}{r_{fc}}} = \frac{1}{\sqrt{n}}$$

$$\Rightarrow \Delta v = \Delta v_A + \Delta v_B = v_{ic} \left\{ \sqrt{\frac{2n}{n+1}} - 1 \right\} + \left\{ 1 - \sqrt{\frac{2}{n+1}} \right\} \frac{1}{\sqrt{n}}$$

$$\Rightarrow \frac{\Delta v}{v_{ic}} = \sqrt{\frac{2n}{n+1}} - 1 + \left(1 - \sqrt{\frac{2}{n+1}} \right) \times \frac{1}{\sqrt{n}}$$

$$\frac{\Delta v}{v_{ic}} = \left(1 - \frac{1}{n} \right) \sqrt{\frac{2n}{1+n}} + \sqrt{\frac{1}{n}} - 1$$

$n \rightarrow \infty$ i.e. r_f becomes very large with respect to r_i

So, v_{fc} by v_{ic} this is nothing, but μ by r_{fc} under root, divided by μ by r_{ic} under root. So thus, we have Δv equal to Δv_A plus Δv_B , is equal to v_{ic} times $2n$ divided by n plus 1 under root, minus 1 plus, and v_{fc} by v_{ic} this we can write as here 1 by n under root and close the bracket, so this implies Δv by v_{ic} . So, in this representation, some simplification can be done, if you try to write for the simplify it, so this can be written as 1 minus 1 by n times $2n$ by 1 plus under root. So, whatever we get here in this place, n is a quantity which we have written as r_f by r_i , so if n tends to infinity, that is r_f becomes very large with respect to r_i .

(Refer Slide Time: 55:22)

Handwritten derivation on a blue background with NPTEL logo in the bottom left. It shows the limit of the ratio of change in velocity to initial velocity as n approaches infinity. The expression simplifies to $(\sqrt{2} - 1)$, which is then related to the ratio of radii r_f/r_i and the eccentricity e .

$$\frac{\Delta v}{v_{ic}} = (1 - 0) \sqrt{\frac{2}{1+0}} + 0 - 1$$

$$\boxed{\frac{\Delta v}{v_{ic}} = (\sqrt{2} - 1)}$$

$r_f \uparrow$ $e \uparrow$
 $e = 1$

Parallel velocity
 $v_p = \sqrt{2} v_c$
 $\Delta v = v_p - v_c = (\sqrt{2} - 1) v_c$

So, once n becomes very large, so this particular quantity can be written as Δv by v_i c , this will become $1 - 0$, and this 2 , here n we can divide by n , so this will become 2 divided by $1 + 0$, plus 1 , 1 by large quantity n is equal to infinity, so this becomes 1 is to 0 $n - 1$. So, what we get here, this is under root $2 - 1$. So, this is the limiting case, so if you remember in the earlier we have written that in the parabolic orbit, velocity is will be given as, root 2 times v circular orbit. And therefore, the difference in the velocity in the parabolic orbit and the circular orbit, $v_p - v_c$ this becomes root $2 - 1$ times v_c , this is parabolic orbit.

So, in this case what is happening, we have been working with the electrical orbit, but as the value of r_f increases, r_f goes up, so similarly e goes up. So, for the electrical orbit, so finally once r_f becomes infinity, so e will be equal to 1 at that time, and once e equal to 1 so this is referent nothing, but to the parabolic orbit, for which the difference in the velocity is given here by this equation, and this equation and this equation both are same there is no difference. So, in the limiting case electrical orbit also this acts as the parabolic orbit. So, we will continue with this, and we will try to find out what will be the efficiency of the Hohmann orbit, the Hohmann transfer and the Bielliptic transfer, and we will try to do some comparison for that in the next lecture. Thank you very much.
