Lecture No. # 03
Particle Kinematics (Contd..)

In the last lecture, we have started particle kinematics. So, we continue with that lecture. So, if you remember, in the last lecture, we derived this expression for the acceleration of a particle as $\frac{d^2s}{dt^2} \hat{e}_t + \frac{ds}{dt} \frac{d\hat{e}_t}{dt}$ plus $\frac{ds}{dt} \frac{d\hat{e}_n}{dt}$ divided by R , so, where R or perhaps, R or ρ , whatever we have taken, this is nothing, but the radius of the curvature. And, this radius of curvature, from the geometry, from your coordinate geometry, you can recall that, this can be written as $1 + \left(\frac{dy}{dx}\right)^2$ to the power 3/2, divided by $\left|\frac{d^2y}{dx^2}\right|$.

Lecture # 3 (3-1) © IIT KGP

Kinematics of Particle

$$\vec{a} = \frac{d^2s}{dt^2} \hat{e}_t + \left(\frac{ds}{dt}\right)^2 \frac{\hat{e}_n}{R}$$
$$R = \frac{\left[1 + \left(\frac{dy}{dx}\right)^2\right]^{3/2}}{\left|\frac{d^2y}{dx^2}\right|}$$

Radius of Curvature,

P

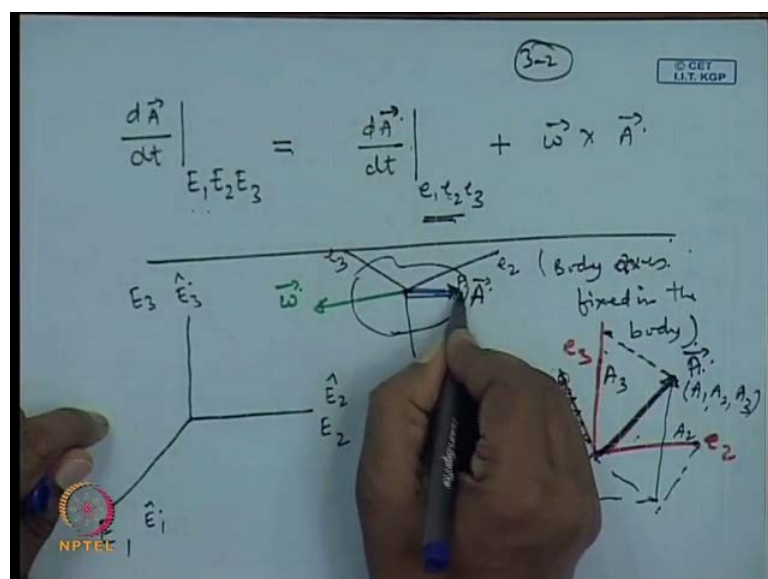

NPTEL

And this, you can, this is a modulus and you can prove this using calculus also. Then, this is a very useful result. So, in that context, we proceed with our further derivation, which will serve us while we work on altitude dynamics, or if you see, one says, once you are putting a satellite, say (()), you have gone into a, an space craft which has a robotic manipulator. And now, you want to study the movement of the robotic arms in

this place. So, what kind of equations you are going to use, you have to study such kind of motion. So, those can be, studied using very simple kinematics. (()) if the moment of inertia, or the other things, they come into picture, then, you have to naturally include the dynamics part also. But the kinematics part, you can obviously, study from this place. What we are going to study now, say, it is a part of our particle kinematics. So, first of all, we will find a derivation, last time as I was stating that, the rate of change of a vector as observed from an inertial reference frame E_1, E_2, E_3 , that is, non rotating reference frame, is equal to the rate of change of this vector, as observed from the e_1, e_2, e_3 , from a moving reference frame, or rotating reference frame, plus $\omega \times A$. So, in that context, we made a reference frame here, E_1, E_2, E_3 , where the unit vectors along this directions are, \hat{E}_1, \hat{E}_2 and \hat{E}_3 and then, we had a rigid body here.

We fixed a triad of axis, termed as e_1, e_2 and e_3 ; it is for the body x ; body axes fixed in the body; so, it is rotating along with the body. So, let us say, ω is the angular velocity of this body, with respect to the inertial reference frame, or, or small ω , or capital ω , whichever notation we want, we can keep. And then, we can point a vector here, in this body, we can take a vector. So, will make a separate figure here, in this place for that; let us say this is our e_1, e_2 and e_3 . And, you have a vector A , whose coordinates can be determined in this reference frame; instead of putting here e_3 , we make it little vertical. So, the coordinate of, you can break it here. So, the coordinate here, of this, can be written as A_1, A_2, A_3 .

(Refer Slide Time: 02:43)

Now, these are the components along A 1 direction, A 2 direction; here, this will be your A 2 and this vertical component, A 3. So, here, some point is there, whose radius vector is A, and let us write it as p; if this is a rigid body, so, naturally, this vector gets fixed, with respect to e 1, e 2 and e 3. Now, we can start writing the equation. Let us say the vector A, we define as A 1, e 1 cap, A 2, e 2 cap, plus A 3, e 3 cap, where the magnitude of A can be written as A 1 square, A 2 square and A 3 square under root. Now, this vector has been written in terms of the components along the body axis, A 1, A 2 and A 3; equally, this vector, if you see from the, this inertial reference frame, or the non rotating reference frame, this is the center of mass here. If you see this vector from this place... So, you can see, it is a component lying along the A 1 direction, A 2 direction and A 3 direction; naturally, this components will be different. They will not be same as A 1, A 2 and A 3 written here, in this place. And, we are using capital notation, capital A to indicate, differ it from the small a, which is often used for acceleration. So, our objective is to find that, this d A by d t is a rate of change of d A by d t as seen from the E 1, E 2, E 3 reference frame, how does it appear.

(Refer Slide Time: 06:37)

$$\vec{A} = A_1 \hat{e}_1 + A_2 \hat{e}_2 + A_3 \hat{e}_3 \quad (3-2)$$

$$|\vec{A}| = \sqrt{A_1^2 + A_2^2 + A_3^2}$$

$$\left. \frac{d\vec{A}}{dt} \right|_{E_1, E_2, E_3} = \frac{d}{dt} (A_1 \hat{e}_1 + A_2 \hat{e}_2 + A_3 \hat{e}_3)$$

$$= \left(\frac{dA_1}{dt} \hat{e}_1 + \frac{dA_2}{dt} \hat{e}_2 + \frac{dA_3}{dt} \hat{e}_3 \right) + \left(A_1 \frac{d\hat{e}_1}{dt} + A_2 \frac{d\hat{e}_2}{dt} + A_3 \frac{d\hat{e}_3}{dt} \right) \Big|_{E_1, E_2, E_3}$$

So, to start with, we can write this equation as d by d t and A we can write as A 1, e 1 cap... Now, let us take the derivative of this. So, this is its derivative and this derivation we are doing with respect to the A 1, A 2, A 3 reference frame. Now, the quantity which are appearing d A 1 by d t, d A 2 by d t and d A 3 by d t, so, these are the rate of change of the components A 1, A 2 and A 3, as seen from the reference frame E 1, E 2

and E 3. So, as we were discussing in the last class that, the rate of change of a scalar, as seen from a non rotating reference frame, here, we have a rotating reference frame and this scalar is present here. If the, this is a fixed point in the rigid body, so, naturally, we can write...So, we take the case 1 here as case 1, point P is fixed in the rigid body. So, if the point P is fixed in the rigid body, so, the vector A which is fixed here, so, the components of this in the, this, the body reference frame, it will remain constant; it will not be changing.

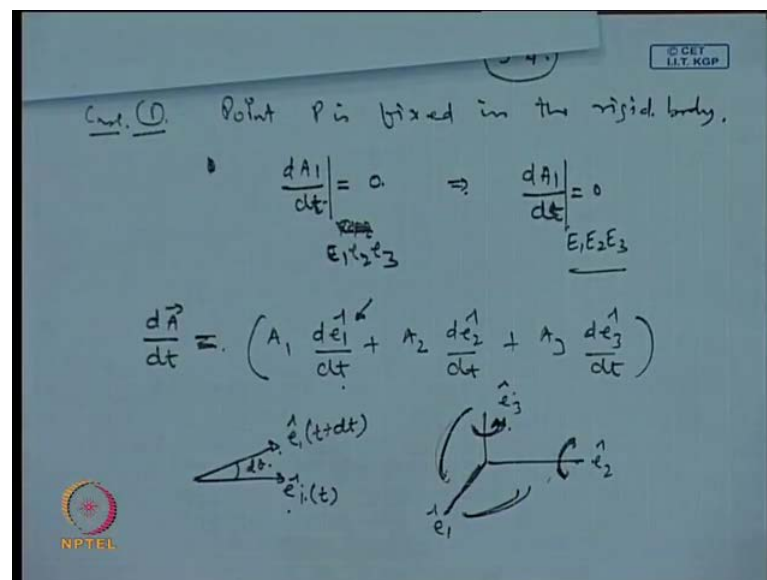

So, what about the rate of change of this components, as seen from the, this non rotating reference frame E 1, E 2 and E 3. So, the last time, as per our discussion that, the scalar, as we see from a rotating reference frame, or from a non rotating reference frame, they, their rate of change will remain same, so, irrespective of their temperature. So, if the temperature raises, if temperature is your, is your scalar, so, if your, you have kept something, some, say some crucible in the, in a rotating reference frame, and you were looking at it, so, the temperature that will be measured there and the rate of change of temperature, it is basically a scalar. So, it will be same, as we see it from the non rotating reference frame. So, what, here we want to state, I want to state here that, the rate of change of a scalar, or the time derivative of a scalar, it is the same, irrespective of whether it is, say, the moving reference frame, or is a rotating reference frame, or non rotating reference frame. So, the rotation of the reference frame, it does not affect the scalar and its derivative.

So, the length of a, length of a fan blade, it is remain same. And, if you contract the length of the blade in the rotating reference frame, which is the fan itself, sitting on the fan, if it is contracted, so, whatever the rate is, of the contraction is there, the same rate will appear also from the non rotating reference frame. So, from that point of view, what we have written here, this $\frac{dA_1}{dt}$, $\frac{dA_2}{dt}$ and $\frac{dA_3}{dt}$, with respect to the E 1, E 2, E 3, so, these are basically the derivatives of the, time derivatives of the scalar components and therefore, they will appear same, as you look from the, either E 1, E 2, E 3 reference frame, or either if you look from the small e 1, e 2, e 3, that is the body reference frame. So, in both of them, it will same, it remains same.

But if the point P is fixed in the rigid body, so, naturally this component, $\frac{dA_1}{dt}$, even in the body reference frame, naturally, it is 0. And therefore, this will appear to be the same also, with respect to the e 1, e 2, e 3. So, this will also appear to be the 0, from

the capital E_1, E_2, E_3 , which is a non rotating reference frame. So, in that case, you can write, $d\vec{A}$ by dt as A_1 times $d\hat{e}_1$ cap by dt plus A_2 times $d\hat{e}_2$ cap by dt plus A_3 times $d\hat{e}_3$ cap by dt . Now, you need to determine this quantity $d\hat{e}_1$ by dt , $d\hat{e}_2$ by dt , $d\hat{e}_3$ by dt . So, we have done earlier this exercise also, if this is a unit vector at time t and this is the unit vector at time t plus dt , this angle is $d\theta$. So, you look from this figure; here, this is a vector \hat{e}_1 ; this is the vector \hat{e}_2 and this is a vector \hat{e}_3 . So, rotation of this vector, it will depend on rotation of this vector, in this plane. And, in this plane, it will depend on the rotation, rotation of this vector will depend on rotation around this x and rotation around this x will affect in this plane. So, in this plane, this rotation will affect; in this plane, in this plane, we have this rotation is affecting; in this plane, this rotation is affecting.

(Refer Slide Time: 10:37)

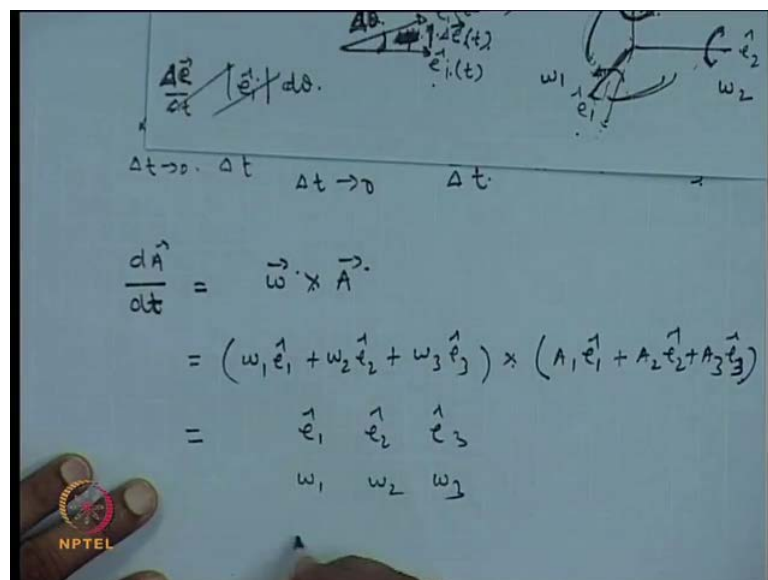

So, this two rotations can be corroborated. Now, we need to work out all of them. So, if we say that, this is the rotating, the rotation about this x , the component of omega vector about this is omega 1; about this axis, this is omega 2 and about this axis, this is omega 3. So, the rotational rate of this, now, we start and let us put this as the, something, we write it as $d\theta$ only.

So, the change is $\Delta \hat{e}_1$ and this change you can write as, \hat{e}_1 cap magnitude times $d\theta$. And therefore, $\Delta \hat{e}_1$ by Δt in the limit, we can write here, limit Δt tends to 0, $\Delta \hat{e}_1$ by Δt ; this we can write as, let us first take the magnitude, and

thereafter we will take the direction part. So, $d\theta$ by dt will be equal to magnitude of \hat{e}_1 times $d\theta$ or $\Delta\theta$ by Δt ; so, here we can show this as the $\Delta\theta$, instead of Δt , to be consistent, and this quantity is nothing, but equal to 1. So, this gets reduced to $\dot{\theta}$. So, $\dot{\theta}$ is nothing, but your ω_3 here, in this place, and ω_3 because, this is rotating like this; if this vector is rotating like this, so, we will write this as the ω_3 . Now, in which direction this vector will change? So, the changed vector will be, as this $\Delta\theta$ becomes smaller and smaller, this will be perpendicular to this \hat{e}_1 vector. So, this is pointing in this ω_3 direction. Now, similarly, \hat{e}_1 can, because this axis is also rotating, so, \hat{e}_1 is also rotating about this axis and for the positive rotation, we are giving the, taking the right hand rule. So, this is rotating anti clock wise here, and about the x_1 axis also, \hat{e}_1 is, we are giving the anti clock wise rotation. Similarly, about the \hat{e}_2 axis, we give the anti clock wise rotation. So, if the rotation is given about this, so, \hat{e}_1 will shift from this place to this place, downward direction. So, similarly, we need to work out for this and the net change then, will be combination of this two. So, over all, this $d\vec{A}$ by dt , this can be written as $\vec{\omega} \times \vec{A}$.

(Refer Slide Time: 16:17)

$$\begin{aligned}
 \frac{d\vec{A}}{dt} &= \vec{\omega} \times \vec{A} \\
 &= (\omega_1 \hat{e}_1 + \omega_2 \hat{e}_2 + \omega_3 \hat{e}_3) \times (A_1 \hat{e}_1 + A_2 \hat{e}_2 + A_3 \hat{e}_3) \\
 &= \begin{vmatrix} \hat{e}_1 & \hat{e}_2 & \hat{e}_3 \\ \omega_1 & \omega_2 & \omega_3 \\ A_1 & A_2 & A_3 \end{vmatrix}
 \end{aligned}$$

We write, break up this part and then, we will come to this to show you what exactly has happened. $\omega_1 \hat{e}_1 + \omega_2 \hat{e}_2 + \omega_3 \hat{e}_3$ plus $\omega_3 \hat{e}_3$ and cross $A_1 \hat{e}_1 + A_2 \hat{e}_2 + A_3 \hat{e}_3$. So, if you break it up, taking the cross product, so, you can write it in this way, $\omega_1 \hat{e}_2 \hat{e}_3$ and ω_1 , ω_2 , ω_3 , A_1 , A_2 , A_3 ; take the

determinant of this and this will yield you, $\mathbf{e}_1 \cap \omega_2 A_3 - A_2 \omega_3 + \mathbf{e}_2 \cap A_1 \omega_3 - \omega_1 A_3 + \mathbf{e}_3 \cap A_2 \omega_1 - A_1 \omega_2$. So, what exactly has happened... We had started with this. So, this term, we are writing as 0; this term, if the vector is fixed, the case 1, we were taking, where the point P is fixed. So, in that case, this part is becoming 0 and only this part we are considering. So, in this part, we need to insert the expression for $d\mathbf{e}_1 \cap$, $d\mathbf{e}_2 \cap$ and $d\mathbf{e}_3$ by $d\mathbf{t} \cap$. And, procedure for doing the same thing, so, $d\mathbf{e}_1$ by $d\mathbf{t} \cap$ we were trying to find out. So, due to one rotational change, we saw that, this is, ω_3 is coming into picture here. So, the angle $\delta\mathbf{e}_1$ by $\delta\mathbf{t}$, because of the rotation about the \mathbf{e}_3 axis, this will be ω_3 and it points in the direction of ω_3 itself. So, this vector becomes $d\mathbf{e}_1 \cap$ by $d\mathbf{t}$; this you can write as $\omega_3 \times \mathbf{e}_3 \cap$. But here, because this is only due to, only due to rotation about \mathbf{e}_3 axis; then, we have to take care of your rotation about the \mathbf{e}_2 axis.

So, these things we will be doing comprehensively in our attitude dynamics part. So, if we continue with this... So, with A_1 , we can see that, with A_1 , ultimately the \mathbf{e}_3 vector is manifesting. So, sorry, the vector region, the direction of the \mathbf{e}_3 and ω_3 is manifesting; sorry, this we write as, where it has gone; let me make another figure here. This is your $\mathbf{e}_1 \cap$ and this is your $\mathbf{e}_2 \cap$ at time t and this is basically due to the rotation of ω_3 here, that it is changing in the $\mathbf{e}_1 \mathbf{e}_2$ plane and this we have written as $\delta\theta$. So, that change, once \mathbf{e}_2 approaches this, this you are writing as, $\mathbf{e}_1 \cap t + \delta\mathbf{t}$ and if this is \mathbf{e}_1 , so, this your $\delta\mathbf{e}_1$.

(Refer Slide Time: 20:36)

$$= \hat{e}_1 (\omega_2 A_3 - A_2 \omega_3) + \hat{e}_2 (A_1 \omega_3 - \omega_1 A_3) + \hat{e}_3 (\omega_1 A_2 - A_1 \omega_2)$$

Left diagram: Vector $\hat{e}_1(t)$ rotates by $\Delta\theta$ to $\hat{e}_1(t+\Delta t)$ around \hat{e}_3 axis. $\lim_{\Delta t \rightarrow 0} \frac{\Delta\theta}{\Delta t} = \omega_3$

Right diagram: Vector $\hat{e}_1(t)$ rotates by $\Delta\phi$ to $\hat{e}_1(t+\Delta t)$ around \hat{e}_2 axis. $\lim_{\Delta t \rightarrow 0} \frac{\Delta\phi}{\Delta t} = \omega_2$

So, as this approaches this, this vector points in the direction of the \hat{e}_2 , not in the direction of the \hat{e}_3 ; but the rotation, rotation which is taking place, $\Delta\theta$ by Δt , this is in the direction of this. This is basically nothing, but your ω_3 . So, in the limit Δt tends to 0, this you can write as ω_3 , in this place. Therefore, the one part of $d\mathbf{A}_1$ by... We had the first part $d\mathbf{A}_1$ by $d\mathbf{t}$ times $d\hat{e}_1$ cap by, sorry; this is A_1 times $d\hat{e}_1$ cap by $d\mathbf{t}$. This is the first part, plus the second part is A_2 times $d\hat{e}_2$ cap by $d\mathbf{t}$; the third part is A_3 times $d\hat{e}_3$ cap by $d\mathbf{t}$. Now, naturally from this place, what we see, this part gets reduced to A_1 times ω_3 and the vector, now, it is directed along the \hat{e}_2 direction. So, \hat{e}_2 cap will manifest here. Similarly, if you give rotation about the \hat{e}_2 axis, we are giving positive rotation, using the right hand rule. So, this is ω_2 here, and then, this vector instead of now taking it up, we can show it going down. And, let us say, this angle, we show it as $\Delta\phi$. So, you consider the rate of change of this $\Delta\phi$; again, you can write this as \hat{e}_1 t and this is \hat{e}_1 t plus Δt . We are considering each rotation separately. So, if it rotates, this is your $\Delta\hat{e}_1$ t, putting cap here, so that, this vector which I changed, as we have discussed in the last lecture, this is nothing, but your $\Delta\phi$ times \hat{e}_1 cap t magnitude. So, this is the magnitude of this vector $\Delta\hat{e}_1$ t.

And, if we divide both sides by Δt and let Δt tends to 0... So, limit Δt tends to 0 and here also, take the limit Δt tends to 0. So, this will give you, this quantity is basically 1. So, this gives you $d\phi$ by $d\mathbf{t}$ and this is nothing, but here, serving as the

omega 3; in this direction, this is serving as omega 2, not as omega 3. And, what is the direction in this case is, you have this vector, the rotation is taking place like this. So, this is, the rate of change of this angle will be pointing in this direction, and this vector, the vector which has to change. So, this vector is associated with the direction, as this approaches this place. So, this is in the negative direction of omega 3. So, we write here, with the same thing here, you can write as omega A 1 times and then, multiplied by omega 2 times omega 3, but with a negative sign. Now, you search for the expression that we have written for, expanded expression we have written here, here, in A 1, where it appears. So, look for that sign; A 1 with omega 3, this is A 1 with omega 3, this is, and e 2 is here.

So, this part is, you consider this is positive sign and then, you look for the A 1 omega 2 and omega 3; A 1 omega 2, A 1 times omega 2 times omega 3; this is your omega 3; this is with a negative sign. So, this way, you can, assemble component-wise, each of them, and then, combine the terms with e 1 cap, e 2 cap and e 3 cap together, and you will get this expression. And, the same expression, I wrote this in a one sort as, d A by d t as omega cross A. So, here finally...

(Refer Slide Time: 28:20)

Handwritten mathematical derivation on a blue background:

Top left: $\frac{d}{dt} (A_1 \hat{e}_1 + A_2 \hat{e}_2 + A_3 \hat{e}_3)$

Top right: $A_1 \frac{d\hat{e}_1}{dt} + A_2 \frac{d\hat{e}_2}{dt} + A_3 \frac{d\hat{e}_3}{dt}$

Middle: $A_1 \omega_3 \hat{e}_2 - A_1 \omega_2 \hat{e}_3$

Bottom left: $\frac{d\vec{A}}{dt} = \vec{\omega} \times \vec{A} + \left(\frac{d\vec{A}}{dt} \right)_{rel}$

Bottom right: \vec{A} is a vector in $\hat{e}_1, \hat{e}_2, \hat{e}_3$ reference frame

Bottom center: $\hat{e}_1, \hat{e}_2, \hat{e}_3 \rightarrow$ non-rotating

So, finally, this expression, once we are reducing it...So, we are writing as d A by d t in E 1, E 2, E 3, this will be equal to omega cross A, if A is a constant vector in e 1, e 2, e 3 reference frame. So, the magnitude of the vector, this vector, the magnitude of this

vector, also becomes a constant in the capital E_1, E_2, E_3 reference frame, which is non rotating. So, you see, if this, how important this conclusion is. So, from here, what we get that, if the vector is fixed in magnitude, then, simply the first part here vanishes and we get the, only the second part as ω cross A . So, this gets reduced to ω cross A . But if this magnitude, the component of the A vector, it is a changing in the body reference frame itself, so, it will also change in the $x y z$ reference frame, and I, as I have stated, the scalar change, the rate of the scalar change, as in, as it appears in a non rotating reference frame, it is the same as from the rotating reference frame. And therefore, in that case, we can write dA by dt , the case 2, A is varying in, and this is case 2, varying in body reference frame, that is in e_1, e_2, e_3 . So, here, in this case, you can write, this is dA by dt with respect to E_1, E_2, E_3 , small e_1, e_2, e_3 plus ω cross A , in this case, as the rate of change of this appears from the e_1, e_2 reference frame.

(Refer Slide Time: 31:10)

Case 2 \vec{A} is varying in body reference frame (e_1, e_2, e_3)

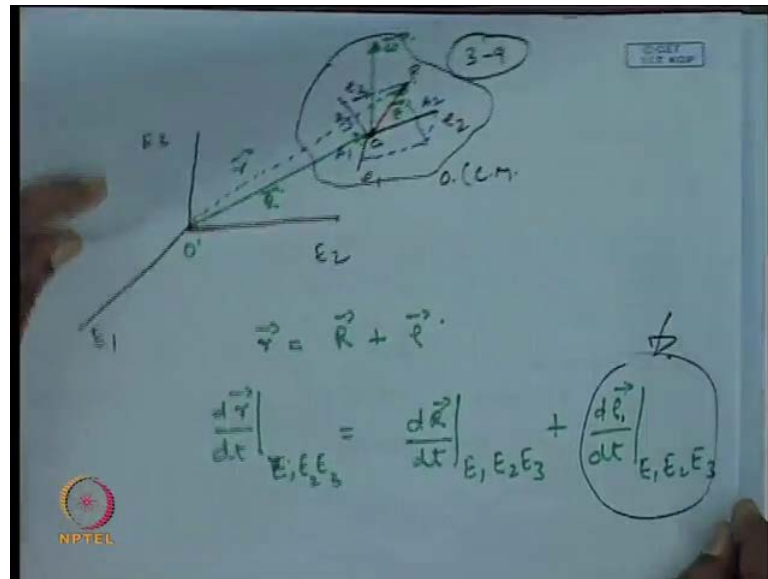

$$\left. \frac{d\vec{A}}{dt} \right|_{E_1, E_2, E_3} = \left. \frac{d\vec{A}}{dt} \right|_{e_1, e_2, e_3} + \vec{\omega} \times \vec{A}$$

$$\left. \frac{d\vec{A}}{dt} \right|_{e_1, e_2, e_3} = (\dot{A}_1 \hat{e}_1 + \dot{A}_2 \hat{e}_2 + \dot{A}_3 \hat{e}_3)$$

So, here, you have, these are the, in the case, the vector A is changing in the magnitude; its components are changing. You just have to take the components of this and the same thing has been written here, in this format. So, here, basically, your dA by dt e_1, e_2, e_3 , this we are writing as $A_1 \dot{e}_1$ cap plus $A_2 \dot{e}_2$ cap plus $A_3 \dot{e}_3$ cap. So, this is going to be the same, as seen from the E_1, E_2, E_3 reference frame, or either from the small e_1, e_2, e_3 body reference frame. So, we have done a part, which was very important for understanding further, our derivations. So, next, we go into, sorry. So, here,

P is a point and say, this point O is the center of mass of this body; this is the point we have taken inside a rigid body and e_1, e_2, e_3 reference frame is fixed in this. And, this reference frame is rotating with an angular velocity of say, ω . So, and this vector, we have written as A . Now, instead of writing this as A , we write this as ρ , and the vector from this place to this place, we write this as R .

(Refer Slide Time: 32:50)

And, the vector joining the point ρ prime and the point P, this we write as r . So, obviously, we can write r equal to R plus ρ and therefore, the rate of change of this, in the E_1, E_2, E_3 reference frame, this can be written as dR by dt E_1, E_2, E_3 plus $d\rho$ by dt E_1, E_2, E_3 . Now, whatever the conclusion we have made in the last part, so, that applies into here, this place. So, this is a vector, which is been referred from this point to this point in the rigid body. So, this vector can be either expressed in the components of the E_1, E_2, E_3 , or in the body components. But here, we will describe this vector in terms of the body components. So, r double dot, we write this as, left hand side, E_1, E_2, E_3 , this will be equal to R double dot E_1, E_2, E_3 plus $d\rho$ by dt ; so, that we have written as, we can write as, $d\rho$ by dt as seen from e_1, e_2, e_3 reference frame and plus ω cross ρ . This is the first derivative that we have taken. So, the, this quantity has been, the quantity, this quantity has been expanded and written in this format. This is, sorry, this is the first derivative; only one point, dot will come; this is the first derivative. Next, we take the second derivative. So, this, we write as $d^2 r$ by $d^2 t$.

t square and this is with respect to E_1, E_2, E_3 reference frame and here, this, we will write as \ddot{r}_{E_1, E_2, E_3} .

So, naturally, we need to differentiate this quantity here, \dot{r}_{E_1, E_2, E_3} , plus, this we will write as $\dot{\rho}_{E_1, E_2, E_3}$ plus $\omega \times \rho$. And, this, we have to do with respect to E_1, E_2, E_3 reference frame. So, expanding this part, because this is a vector, again \dot{r} is a vector, which is in the E_1, E_2 reference frame and we are taking the derivative in that itself. So, it does not make any difference. We can directly write this as \ddot{r}_{E_1, E_2, E_3} and plus $\frac{d}{dt} \dot{\rho}$. Now, this is $\dot{\rho}$ is a vector, which was in e_1, e_2, e_3 . So, we need to drop out this symbol here; this symbol, may be, this symbol we can take as e and this symbol we can keep as capital E , to abbreviate here, in every place.

(Refer Slide Time: 35:34)

$$\ddot{r}_{E_1 E_2 E_3} = \ddot{r}_{E_1 E_2 E_3} + \frac{d\dot{\rho}}{dt}_{e_1 e_2 e_3} + \omega \times \dot{\rho}$$

$$\frac{d^2 \dot{r}}{dt^2}_{E_1 E_2 E_3} = \frac{d}{dt} \left(\ddot{r}_{E_1 E_2 E_3} + \dot{\rho}_{e_1 e_2 e_3} + \omega \times \dot{\rho} \right)$$

$$= \ddot{r}_{E_1 E_2 E_3} + \frac{d}{dt} \left(\dot{\rho}_e \right) + \frac{d}{dt} (\omega \times \rho)$$

So, here, we can put as e and outside we can keep as E . So, this, we can replace by E . And then, of course, we have to write $\frac{d}{dt} \omega \times \rho$ and this is with respect to this E . So, we have \ddot{r}_{E_1, E_2, E_3} , this becomes... Now, differentiate the quantity which is written inside; $\dot{\rho}$, as it appears here, if you remember from the last part, as we have written, so, this can be written as $\dot{\rho}_1 \hat{e}_1 + \dot{\rho}_2 \hat{e}_2 + \dot{\rho}_3 \hat{e}_3$ and plus the next one again, we have to write. So, this term we can write as, $\frac{d\omega}{dt} \times \rho$; this is with respect to E and plus $\omega \times \frac{d\rho}{dt}$; this is with respect to E . Now, we have to take care of this particular part. As proceeding in the

last part, so, we can write here directly as, $\rho_1 \ddot{e}_1$ plus $\rho_2 \ddot{e}_2$ and $\rho_3 \ddot{e}_3$ and this we are writing with respect to E. But this is also equivalent to writing it with respect to the small e, as we have argued just before; exactly we have done, as for the A vector, we are doing the same operation here. And, the other part of this can be written as $\rho_1 \dot{e}_1$ times $d e_1$ cap by $d t$ plus $\rho_2 \dot{e}_2$ times $d e_2$ cap by $d t$ plus $\rho_3 \dot{e}_3$ times $d e_3$ cap by $d t$ and this is for, with respect to this capital E reference frame and of course, this, this quantity we can write as $\omega \dot{\rho}$ and this is ρ , and the quantity which is present here, this is $\omega \times \rho$. Now, $d \rho$ by $d t$ with respect to E we have already written as $d \rho$ by $d t$ with respect to the small e, that is, with respect to the body reference frame plus $\omega \times \rho$.

(Refer Slide Time: 38:40)

$$\begin{aligned}
 \ddot{\mathbf{r}}_E &= \ddot{\mathbf{R}}_E + \left. \frac{d}{dt} \left(\dot{\rho}_1 \hat{e}_1 + \dot{\rho}_2 \hat{e}_2 + \dot{\rho}_3 \hat{e}_3 \right) \right|_E + \left. \frac{d\vec{\omega}}{dt} \right|_E \times \vec{\rho} \\
 &\quad + \vec{\omega} \times \left. \frac{d\vec{\rho}}{dt} \right|_E \\
 &= \ddot{\mathbf{R}}_E + \left(\ddot{\rho}_1 \hat{e}_1 + \ddot{\rho}_2 \hat{e}_2 + \ddot{\rho}_3 \hat{e}_3 \right)_{E \equiv e} \\
 &\quad + \left[\dot{\rho}_1 \frac{d\hat{e}_1}{dt} + \dot{\rho}_2 \frac{d\hat{e}_2}{dt} + \dot{\rho}_3 \frac{d\hat{e}_3}{dt} \right]_E + \vec{\omega} \times \vec{\rho} \\
 &\quad + \vec{\omega} \times \left[\left. \frac{d\vec{\rho}}{dt} \right|_e + \vec{\omega} \times \vec{\rho} \right]
 \end{aligned}$$

Now, writing this equation here, on the next page, so, we have $\ddot{\mathbf{r}}_E$, which is the acceleration in the inertial frame, this can be written as $\ddot{\mathbf{R}}_E$; and the term which is present here, which we have writing as $\ddot{\mathbf{a}}_e$, so, this term is basically, the acceleration with respect to the body reference frame; because, as we have discussed, the time derivative of a scalar, it does not depend on the reference frame. So, like the temperature in a rotating reference frame and so, we have the temperature in a rotating reference frame. So, its time derivative, it will be same from a non rotating reference frame also; the time derivative does not get affected. So, we are taking here, the time derivative of ρ_1 , $\rho_2 \dot{\rho}$, $\rho_3 \dot{\rho}$. The, here the, E notation, which is for the inertial reference frame, we replace it by a small E, to indicate this is with respect to the

body reference frame, and therefore, we will use a \mathbf{e} for this. So, we write here a \mathbf{e} for this acceleration. Now, this acceleration, this you can write as $\boldsymbol{\omega} \times \dot{\boldsymbol{\rho}}$; for as earlier described, this, this is \mathbf{e}_1 , \mathbf{e}_2 and you are taking the derivative of this. So, we can, earlier I have proved this, how to work out this. So, here, you can replace this in terms of $\boldsymbol{\omega} \times \dot{\boldsymbol{\rho}}$. So, once this is done, then the last, this term is remaining $\dot{\boldsymbol{\omega}} \times \boldsymbol{\rho}$ and then finally, we have this term here. So, this is your, basically $\dot{\boldsymbol{\rho}}$ with respect to the body reference frame. So, we can write here $\boldsymbol{\omega} \times \dot{\boldsymbol{\rho}}$ plus $\dot{\boldsymbol{\omega}} \times \boldsymbol{\rho}$. And now, accumulating the terms together wherever possible and this $\dot{\boldsymbol{\rho}}$, we can replace as \mathbf{v} , and I can put a \mathbf{e} , to indicate this is with respect to the body reference frame, and this also, we replace by \mathbf{v} and here, $\boldsymbol{\omega} \times \boldsymbol{\omega} \times \boldsymbol{\rho}$.

So, here, this one and this, this can be combined to give $2 \boldsymbol{\omega} \times \mathbf{v}$ and plus $\dot{\boldsymbol{\omega}} \times \boldsymbol{\rho}$ plus... So, this term is your Coriolis term; this term, you can identify as the centripetal acceleration. For very simple cases, you can check it; say, your $\boldsymbol{\omega}$, you can write as ω times \mathbf{e}_3 . If you are writing this very simple case, so, the $\boldsymbol{\omega} \times \boldsymbol{\omega} \times \boldsymbol{\rho}$ and the $\boldsymbol{\rho}$ vector, you can write as, say again, $\boldsymbol{\rho}$ vector, we described as ρ times \mathbf{e}_1 . So, this will become ω times \mathbf{e}_3 cross ω times \mathbf{e}_3 cross ρ times \mathbf{e}_1 . Now, check from this place; this is ω^2 and ρ^3 times ρ^1 , this is nothing, but ρ^2 . So, this becomes \mathbf{e}_3 times \mathbf{e}_2 and \mathbf{e}_3 times \mathbf{e}_2 and here, we put the ρ which is present here. So, this becomes ω^2 times ρ and \mathbf{e}_2 times \mathbf{e}_3 times \mathbf{e}_2 ; this is minus \mathbf{e}_1 . So, this is minus \mathbf{e}_1 . So, basically, what it shows that, your $\boldsymbol{\rho}$ vector, this is along the even direction; you have taken from here that, this is your $\boldsymbol{\rho}$ vector. So, this indicates that, this acceleration is directed towards opposite to the $\boldsymbol{\rho}$ vector; that is, it is directed towards the center of the point about which the rotation is taking place. So, this is basically your centripetal acceleration in inertial reference frame and this is the Coriolis force, that we call, the Coriolis force; these are basically the Coriolis force...

(Refer Slide Time: 42:57)

$$\begin{aligned}
 &= \ddot{\mathbf{r}}_E + \dot{\mathbf{a}}_E + \underline{\underline{\boldsymbol{\omega} \times \mathbf{v}_E}} + \underline{\underline{\boldsymbol{\omega} \times \dot{\mathbf{r}}_E}} + \underline{\underline{\boldsymbol{\omega} \times \mathbf{v}_E}} + \underline{\underline{\boldsymbol{\omega} \times (\boldsymbol{\omega} \times \mathbf{r}_E)}} \\
 &= \ddot{\mathbf{r}}_E + \dot{\mathbf{a}}_E + \underline{\underline{2(\boldsymbol{\omega} \times \mathbf{v}_E)}} + \underline{\underline{\boldsymbol{\omega} \times \dot{\mathbf{r}}_E}} \\
 &= \ddot{\mathbf{r}}_E + \dot{\mathbf{a}}_E + \underline{\underline{2(\boldsymbol{\omega} \times \mathbf{v}_E)}} + \underline{\underline{\boldsymbol{\omega} \times (\boldsymbol{\omega} \times \mathbf{r}_E)}}
 \end{aligned}$$

Coriolis Acc. \downarrow Centrifugal Acc. \checkmark

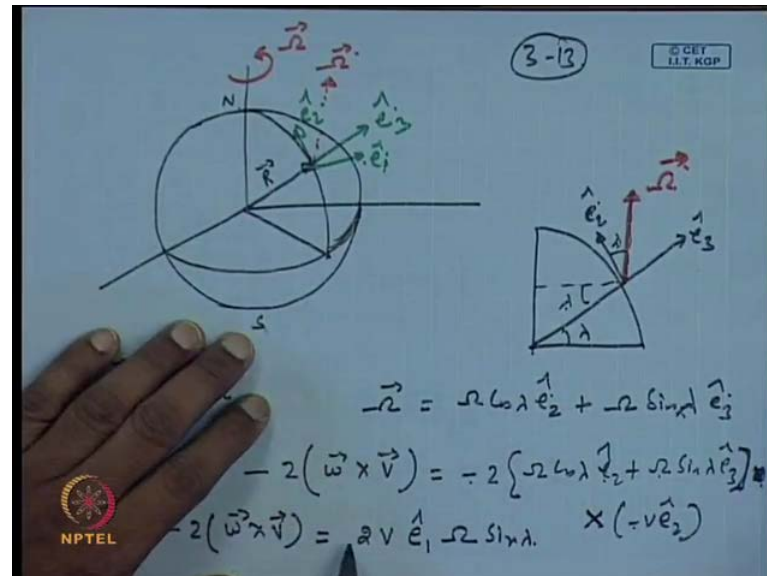

$\boldsymbol{\omega} = \omega \mathbf{e}_3$

You will be able to see it in the, if you are in a rotating body reference frame and this is related to the angular acceleration. This term is nothing, but your angular acceleration and this multiplied by rho. So, acceleration related to the angular acceleration, this term becomes. So, here we can... So, to show the effect of the Coriolis acceleration, we take the case of, of the earth, and say, this is the R vector and here, we have the body reference frame which is \mathbf{e}_1 directed radially outward, \mathbf{e}_3 cap; \mathbf{e}_1 is in the East direction and \mathbf{e}_2 is in the North direction. So, earth is rotating about this axis, with capital omega.

So, here we can show that, this is the angular velocity of the, this body frame. Now, I will take this quadrant only and show this picture here, separately. \mathbf{e}_3 cap, \mathbf{e}_2 cap; this is your lambda. So, this will be lambda; this is angular acceleration vector; this angle will be lambda. So, in the \mathbf{e}_2 direction, this capital omega vector, this you can write in the body reference frame as capital omega cos lambda times \mathbf{e}_2 , taking component along this direction and plus sin lambda is component along this direction multiplied by \mathbf{e}_3 . Now, suppose the wind is coming from the North Pole; this is your North Pole and this is, below the South Pole is there. So, wind is coming from this direction. So, here, we have, I can show that, the wind is in that direction; \mathbf{v} I can write as minus v times \mathbf{e}_2 cap. So, the Coriolis term, that becomes $2 \boldsymbol{\omega} \times \mathbf{v}$. So, this is minus 2 times omega, from here we can insert... So, this is capital omega cos lambda \mathbf{e}_2 cap plus capital lambda \mathbf{e}_3 cap cross \mathbf{v} , which is minus v times \mathbf{e}_2 cap. So, this implies, this

quantity becomes minus minus, this gets plus, and we can write $2v$, $e_2 \times e_2$ cross product, this will vanish here; we can put the cross product here, in this place.

(Refer Slide Time: 47:58)

So, $e_2 \times e_2$ vanishes and we have to take the cross product of this e_3 cap cross e_2 cap, this is e_1 cap minus. And then, we have to take care of this capital lambda. So, capital lambda we can put here and then, we have the sin lambda and this is within minus sign.

So, what it gives that, minus 2 times omega cross v; this is your $2v$ capital omega sin lambda times e_1 cap. So, this Coriolis acceleration in the body reference frame...So, your body reference frame is shown by this green line. So, it is acting in the direction of negative e_1 direction. So, it is acting in this direction. So, this is the East direction; this is your East. This is local vertical and here, this is your North direction. At any point, if we identify like this, this is your North direction. So, East, North and this is vertically up. So, this is the West direction. So, this, we can shown here as the West.

So, if the wind starts from this direction, so, it will turn towards the West; and that is what happens. So, in the northern hemisphere, we will see that, the, if you read your geography book, you will see that, the wind which starts from the North Pole, so, they turn towards the West. So, this is your North Pole and this is your South Pole. This is equator. So, they will turn toward the left hand, and this happens, because of the presence of this Coriolis acceleration. So, I have shown the Coriolis term here; then, I have shown the centripetal term here; and this is basically, due to the increase in the

angular velocity; remember that, in the body reference frame, once we take it to the body reference frame, by writing, I can write this as \ddot{r}_E minus \dot{R}_E double dot minus 2 times ω cross v_E minus ω dot cross ρ minus ω cross ω cross ρ ...

(Refer Slide Time: 51:22)

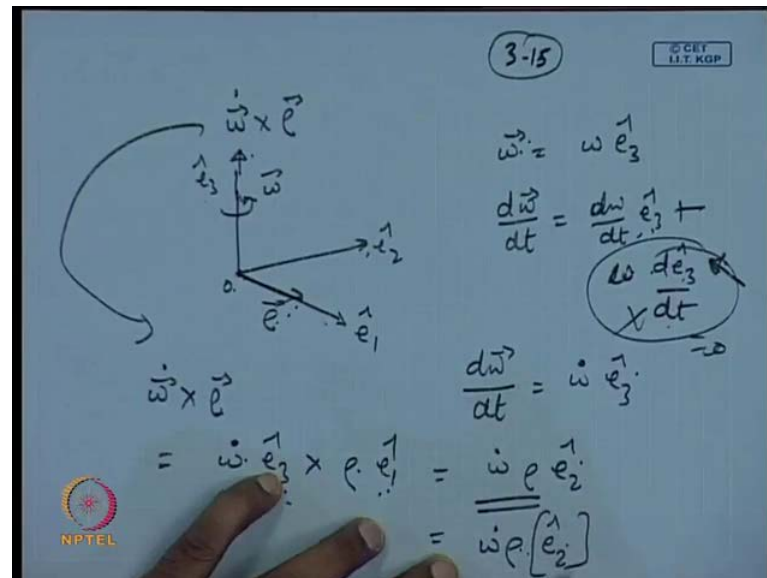

So, once you are looking in the body reference frame, so, this term which is present here, this is basically, your, the negative term that I was showing, the Coriolis term, and this is your (()) centripetal term; we will write this as, showed this as the centrifugal force, because in the body reference frame, what you will fill, is the centrifugal force. So, this is gets a centripetal term, once we change the side, once we are looking from the, relative to the body reference frame; so, centripetal will appear as the centrifugal one. And, this is basically related to your tangential acceleration, because of the increase in the, increase in the angular speed. So, we have to determine this $\dot{\omega}$ cross ρ term.

So, we can take body reference frame e_1, e_2, e_3 cap. Now, ω is a vector, which is directed along this direction. And, this vector is, because we, here, we will take a simple case that, ω is directed along this. So, we can write ω equal to ω times e_3 cap. So, we can write $d\omega$ by dt , this is equal to $d\omega$ by dt times e_3 cap plus ω times $d e_3$ cap by dt . Now, we can look from this place that, here $d e_3$ by dt , because the rotation is taking place about the, this body axis only. So, there is no change in the direction of the e_3 cap, unlike the earlier one. So, this, we can

drop it out; this becomes 0 and here, we can write $d\omega$ by dt equal to $\omega \dot{e}_3$. So, this term gets reduced to $\omega \dot{e}_3 \times \rho$; this will become $\omega \dot{e}_3$, and ρ is basically, we are taking here, in this direction.

(Refer Slide Time: 54:40)

So, this is your ρ vector; so, $\omega \hat{e}_3$ and ρ vector is $\rho \hat{e}_1$. So, this becomes $\omega \dot{\rho}$ and $\hat{e}_3 \times \hat{e}_1$, this is nothing, but your \hat{e}_2 . So, now, you can see that, $\omega \dot{\rho} \hat{e}_2$, this is representing a vector in the direction of \hat{e}_2 . So, \hat{e}_2 is in this direction. So, if you, this is the vector and if this is rotating, so, this is pointing that, this acceleration is directed in this direction. And, the same thing, if you look from the body reference frame, so, the negative sign will come into picture and you just have to put a negative sign before that, and this gets into the opposite direction. So, in the body reference frame, it will appear in the opposite direction.

So, thus, we conclude this part on the kinematics of particle. In the next lecture, so, we will start with the particle dynamics. So, in the particle dynamics, in the space dynamics, we are concerned with the heavenly bodies. So, we will look into the dynamics of the, basically, we are going to work with the dynamics of the heavenly bodies, or the satellites. So, when the earth is here, around the earth a satellite is moving, and there is some other planet. So, we will explore all this things in the future lecture. So, we stop here, thank you very much.
