Analysis of Electro and Magneto Rheological Fluid Flow

(Refer Slide Time: 04:55)

Valve/Flow Mode
 pressurized flow between two ^{parallel} surfaces
 - Poiseuille

Shear Mode
 Flow between two ^{parallel} surfaces having
 relative motion with respect to each other
 - Couette flow

Squeeze Mode

Today, we will continue our discussion on ER and MR fluids. So, ER and MR fluids are used in two main different modes, one is valve mode and another is shear mode. So, valve mode involves. It is a pressurized flow between two surfaces we can say. So, here is a device that uses the fluid in valve mode. Now, the pressure at these two sides can be different and that pressure gradient causes a flow in between these two surfaces and that is what valve mode is.

So, here we can say that these two surfaces do not have any relative motion, where the fluid has a relative motion with respect to these two surfaces. And shear mode is a different mode. Here we can see that this piston moves and accordingly this surface moves and this surface remains constant. So, it is a flow between two surfaces having relative motion with respect to each other.

Now, these surfaces are first of all they are parallel surfaces. So, we must use the word parallel. They are all parallel surfaces. Now, this corresponds to a flow named Poiseuille Flow and this corresponds to Couette flow. So, here it is a pressure mode, here it is a shear

mode and apart from that there is also another kind of mode possible that is called squeeze mode, where the flow happens between two plates which have movement along each other.

So, there is a squeeze mode also. In squeeze mode again we have two surfaces and if the field is along this direction the the plate also have relative motion along this direction. So, maybe this plate keeps coming closer to this. So, the fluid layer between them is squeezed. However, in this mode also the lateral flow is often considered to be similar to the first case and this mode is less common as compared to the first two modes.

Now, we will discuss these two modes in more details. So, we will consider a rectangular flow passage between two plates and analyze the flow. Now, in most of the applications, the flow passage is annular. For example, if I look at this then in 3D, the actual view looks like the rotated version of it with respect to this axis. So, it is a cylindrical and there is a cylindrical annular space between these two plates and that is where the flow takes place.

Same thing happens here as well as here also. So, these are all annular places where the flow takes place. However, we will do it for rectangular flow passage because that is simpler to understand and once we understand the rectangular case, its extension to the cylindrical annular case is much straightforward.

(Refer Slide Time: 10:54)

Governing Equation (Rectangular flow passage)

$$-(P + \frac{\partial P}{\partial x} \Delta x) b \Delta y + P b \Delta y + (\tau + \frac{\partial \tau}{\partial y} \Delta y) \Delta x b - \tau \Delta x b = \rho \Delta x \Delta y b \frac{\partial v}{\partial t}$$

$$\Rightarrow -\frac{\partial P}{\partial x} + \frac{\partial \tau}{\partial y} = \rho \frac{\partial v}{\partial t}$$

quasi-steady flow $\frac{\partial v}{\partial t} = 0$

$$\boxed{-\frac{\partial P}{\partial x} + \frac{\partial \tau}{\partial y} = 0}$$

The diagram shows a rectangular element of width Δx and height Δy between two horizontal plates. The top plate is at $y = \Delta y$ and the bottom plate is at $y = 0$. The element is centered at $y = \Delta y/2$. The pressure on the left face is P and on the right face is $P + \frac{\partial P}{\partial x} \Delta x$. The shear stress on the top face is $\tau + \frac{\partial \tau}{\partial y} \Delta y$ and on the bottom face is τ . The velocity v is shown as a vector pointing to the right. A small video inset of a person is visible in the bottom right corner of the slide.

So, let us now understand the flow. Before going to any of these modes, let us define the governing differential equations for that because these two modes generally differ by the corresponding boundary conditions.

So, let us define the governing equations. So, it is a rectangular flow area. We can consider here that we have two parallel plates between which the fluid is flowing and let us consider a small area from it. So, we can consider this as x axis, this as y and this as z. Now we are looking at the x y plane. The dimension along z can be considered to be b. So, this entire flow passage has dimension b along the z axis. Now let us look a small part of it of size Δx Δy . So, this is Δx , this is Δy . So, let us call it P.

The pressure here is P plus ΔP by Δx multiplied by Δx and there is velocity gradient along the y axis and that gives rise to shear stress. So, the shear stress here we can write as τ plus $\Delta \tau$ by Δy multiplied by Δy and here it is Δy . Now all we do is, we write the equilibrium equation of it and let us say that this small fluid element has a velocity u and it is as an acceleration Δu by Δt . So, if I write the equation of equilibrium if I balance all the forces and equate that to mass into acceleration it looks like this. P plus ΔP by Δx multiplied by Δx .

So, that is the pressure here and the pressure multiplied by the area is the force. The area of this surface is this height which is Δy multiplied by b that is the dimension along the z axis. So, it is b multiplied by Δy then minus here we have P multiplied by the area. So, it is P multiplied by b multiplied by Δy . The force corresponding to this stress is this stress multiplied by this dimension which is Δx multiplied by b .

So, it is τ plus $\Delta \tau$ by Δy multiplied by Δy into Δx into b and here we have τ multiplied by Δx into b and that is equal to mass into acceleration. So, if the density of the fluid is ρ , the entire volume is Δx Δy into b that is the mass of it and into acceleration means Δu by Δt . So, that is the entire balance equation and then if we cancel the common terms, now here this has to be a positive sign because this pressure has a direction in the positive x axis. So, after cancelling the equal terms what we get is ΔP by Δx plus $\Delta \tau$ by Δy is equal to ρ into Δu by Δt . Now we can say that this flow is a steady flow or say quasi steady flow.

In that case, Δu by Δt is 0. So, quasi steady flow this tells me that Δu by Δt is 0 if I make that approximation finally, the governing differential equation that we get is ΔP by Δx plus $\Delta \tau$ by Δy equal to 0. So, that is our governing differential equation. Now here depending on the flow type whether it is a valve mode or shear mode we have to put the appropriate boundary condition and depending on whether there is an electric field applied or not accordingly, this fluid constitutive relation will change and the solution would differ. Now let us look into the specific cases.

Before going there, one thing to note is this has a negative sign and this has a positive sign. So, finally, this is a negative quantity and the constitutive relation is modified as this. So, I have to put a negative sign here. So, this is our governing differential equation.

$$-\frac{\partial P}{\partial x} + \frac{\partial \tau}{\partial y} = \rho \frac{\partial u}{\partial t}$$

$$-\frac{\partial P}{\partial x} + \frac{\partial \tau}{\partial y} = 0$$

(Refer Slide Time: 15:27)

Flow Mode

$$-\frac{\partial P}{\partial x} + \frac{\partial \tau}{\partial y} = 0$$

No field applied $\tau_y = 0$

$$\tau = \mu \dot{\gamma} = \mu \frac{\partial u}{\partial y}$$

$$\frac{\partial P}{\partial x} = -\frac{4P}{L} = \frac{P_2 - P_1}{L}$$

$$\mu \frac{\partial^2 u}{\partial y^2} = -\frac{4P}{L} \Rightarrow \mu \frac{\partial^2 u}{\partial y^2} = -\frac{4P}{L} y + A$$

$$\Rightarrow \mu u = \frac{-4P y^2}{2L} + Ay + B$$

Diagram: A channel of height d between two plates. The top plate is at $y = d$ and the bottom plate is at $y = 0$. Both plates are fixed, so $u = 0$ at both boundaries. The x axis is horizontal and the y axis is vertical. The text "No slip boundary condition" is written near the bottom plate.

Now let us go to special cases. So, there is something called a flow mode or the valve mode. In the flow mode, our consideration is this. We have two plates which are separated by a distance d these are x axis, this is y and again the dimension along z axis is b and in between these two domains, the fluid flow follows the governing differential equation that we derived minus $\frac{\partial P}{\partial x} + \frac{\partial \tau}{\partial y} = 0$. Now let us come to the boundary condition. Here these two plates are fixed.

So, here the boundary condition is $u = 0$ and here is also $u = 0$ and that is called a no slip boundary condition. Now first we would analyze it for a case when there is no actuation is there which means there is no yield. There is no question of any yield happening because $\tau_y = 0$. There is no electric field applied here. Now in this case, our τ is μ multiplied by $\dot{\gamma}$ and we are representing the velocity along x direction as u .

So, if the velocity along x direction is u , the $\dot{\gamma}$ is $\frac{\partial u}{\partial y}$. Now in the solid case, we are denoting generally the displacement as u . So, $\frac{\partial u}{\partial y}$ would have been a $\dot{\gamma}$ just the shear strain. Here u is our velocity which is the time derivative of

displacement. So, $\frac{\partial u}{\partial y}$ is $\dot{\gamma}$ which is time derivative of γ and that can be written as $\mu \frac{\partial u}{\partial y}$.

So, τ is equal to $\mu \frac{\partial u}{\partial y}$. If I put this constitutive relation here and also if we consider the fact that there is difference of pressure at two sides P_1 and P_2 which are separated by a length L then $\frac{\partial P}{\partial x}$ is $\frac{P_2 - P_1}{L}$. So, after we put everything in the approximation, the equation looks like this. Then if we integrate it once, it becomes $\mu \frac{\partial u}{\partial y} = -\frac{\Delta P}{L} y + A$, maybe a constant and again if we further integrate it becomes $\mu u = -\frac{\Delta P}{2L} y^2 + Ay + B$. Now our job is to evaluate these two constants.

If I want to evaluate these two constants we just have to apply the boundary condition that at $y = 0$, u is 0 and at $y = d$, u is 0.

$$\mu u = -\frac{\Delta P y^2}{2L} + Ay + B$$

(Refer Slide Time: 20:34)

at $y=0$ $u=0$ at $y=d$ $u=0$

$\Rightarrow A = \frac{d}{2} \frac{\Delta P}{\mu L}$ $B = 0$

$u(y) = \frac{\Delta P}{2\mu L} (d-y)y$

$u\left(\frac{d}{2}\right) = \frac{\Delta P d^2}{8\mu L}$

$\tau(y) = \mu \frac{\partial u}{\partial y} = \frac{\Delta P}{L} \left(\frac{d}{2} - y\right)$

Equivalent velocity u_m (constant along y and z)
Flow rate corresponding to $u_m =$ Flow rate corresponding to $u(y)$

So, at $y = 0$, u is 0 and at $y = d$, u is 0 and that gives us the values of A and B and A becomes equal to $\frac{d}{2} \frac{\Delta P}{\mu L}$ and B becomes equal to 0. So, after putting everything, $\mu \frac{\partial u}{\partial y}$ becomes $\frac{\Delta P}{2\mu L} (d - y)$. Now if I want to find out the value of u at $y = \frac{d}{2}$ by putting $y = \frac{d}{2}$, the expression comes to be $\frac{\Delta P d^2}{8\mu L}$. Now if I plot it, the variation of the u with respect to y it looks like this.

So, here it is 0. Here it is 0 and here the value is $\frac{\Delta P d^2}{8 \mu L}$. Now, that we have found out the velocity profile. Our next job is to find out the strain rate and stress. Now we know that τ as a function of y is $\mu \frac{du}{dy}$ and if I differentiate this by y and multiplied by μ finally, the expression comes to be $\frac{\Delta P}{L} (d - y)$. So, the velocity profile looks like this if you have the right side of the velocity profile.

If we draw the stress profile it looks like this. So, here I have maximum negative stress. Here I have maximum positive stress and these two values are same. These value and these value are same. Whatever it is here the same thing is here.

Only they differ by sign. So, we have the highest stress magnitude at the top and bottom surface. At the mid zone, the stress is 0 and that we can see here also. If I draw a tangent to this curve, the slope is 0 and that is what we can see $\frac{du}{dy}$ is 0 here. So, the stress is 0 at the middle. Now, let us consider a quantity which is equivalent velocity u_m .

So, we define this quantity as a velocity which is constant throughout the depth and throughout the width, but that gives me the same flow rate. So, the flow rate corresponding to u_m which is constant along y and z . So, flow rate corresponding to this u_m is equal to flow rate corresponding to u as a function of y . So, for that, we have to find out the actual flow rate which is corresponding to the actual velocity distribution and then we will find out what can be the flow rate as a function of u_m if I assume it to be constant and then you can equate those 2 quantities and that will give me something called u_m .

$$u(y) = \frac{\Delta P}{2\mu L} (d - y)y$$

$$u\left(\frac{d}{2}\right) = \frac{\Delta P d^2}{8\mu L}$$

$$\tau(y) = \mu \frac{\partial u}{\partial y} = \frac{\Delta P}{L} \left(\frac{d}{2} - y\right)$$

(Refer Slide Time: 24:19)

Actual flow rate
 $Q = \int_{y=0}^d u b dy = \frac{\Delta P b}{2 \mu L} \left(\frac{dy^2}{2} - \frac{y^3}{3} \right) \Big|_0^d$
 $= \frac{\Delta P b d^3}{12 \mu L}$

Flow rate corresponding to u_m $Q_m = b d u_m$
 $Q = Q_m \Rightarrow u_m = \frac{\Delta P d^2}{12 \mu L}$

Force to maintain the flow $F = \Delta P b d$
 Equivalent damping $C_{eq} = \frac{F}{u_m} = \frac{12 \mu L b}{d}$

Now, Q the actual flow rate is equal to from y equal to 0 to d and that we can get by integrating this quantity and that gives us the flow rate as $\Delta P b$ by $2 \mu L$ multiplied by d square by 2 minus y cube by 3 which is evaluated between at 0 and d are the limits.

So, finally, it comes to be ΔP multiplied by $b d$ cube by $12 \mu L$ and then we have flow rate corresponding to u_m and that is equal to $b d$ multiplied by u and that let us call it Q_m . So, if we equate Q equal to Q_m that gives us u_m as $\Delta P d$ square by $12 \mu L$. Now, we will try to define something called equivalent damping for the system. So, that equivalent damping would be defined as a force which is required to maintain this flow divided by this velocity u_m and that is our equivalent damping. So, for that let us find out the force first.

Now, the force to maintain the flow which we can find out as a function of the pressure and the dimensions $b d$ because this pressure ΔP is applied across a section which has depth d and width b . So, the total force is ΔP minus $b d$. Then if I divide this force F by u_m that would give me the equivalent damping. So, equivalent damping is C_{eq} equal to F by u_m and finally, the quantity comes to be $12 \mu L b$ by d . So, that is the equivalent damping when there is no electric or magnetic field applied.

$$Q = \int_{y=0}^d u b dy = \frac{\Delta P b}{2 \mu L} \left(\frac{dy^2}{2} - \frac{y^3}{3} \right) \Big|_0^d = \frac{\Delta P b d^3}{12 \mu L}$$

$$Q_m = b d u_m$$

$$u_m = \frac{\Delta P d^2}{12 \mu L}$$

$$C_{eq} = \frac{F}{u_m} = \frac{12\mu Lb}{d}$$

(Refer Slide Time: 29:32)

Non-zero field applied

$$\tau = \tau_y \text{sign}(\dot{\gamma}) + M\dot{\gamma} \quad |\tau| > \tau_y$$

Smart Structure

Now, we will consider case where there is non-zero field applied. Now, to understand this non-zero case, we have to understand few things first. Again if we draw the entire flow area, it looks like this and under the zero applied field, the stress distribution took this form. So, when there is a field applied suppose plus minus plus minus plus minus, there would be some finite value of the yield stress. Now, no matter how much pressure we apply, the stress at the mid part of it at $d/2$ is going to be 0.

If I apply higher pressure, only this diagram is just going to change like this, but it would always cross the zero line at the middle. So, no matter what pressure we apply at the middle, the stress is going to be 0. So, this is our $d/2$. This is $d/2$. So, around the midline there would be an area where the stress is always less than the yield stress.

So, that part would behave like a solid. Now, if the applied pressure is more than the thickness of that pre yield region is going to be less. If the applied pressure is less then that pre yield region is going to be more for a given electrical or electrical mechanical field. Now, initially we do not know the size of that pre yield region. The region that behaves like a solid. So, let us assume that the thickness of that region is δ .

Now, we can denote a region like this which has a thickness δ and that region is the pre yield region and from the bottom plate to the starting of the pre yield region, let us denote that dimension as y_1 and again the other dimension to the end of the pre yield region let us

denote as y_2 . So, now while applying the boundary condition, we have to apply it accordingly. Here we have the no slip boundary condition, u equal to 0, u equal to 0. This parts behave like a solid. So, in this part there is no flow which means $\dot{\gamma}$ is 0 here which also means that $\frac{du}{dy}$ is 0 in this mid block which has a pre yield region.

So, that means, that at this line and at this line, $\frac{du}{dy}$ is 0 and that $\dot{\gamma}$ should be continuous throughout. There should not be any jump in between. So, the boundary condition that we apply here is $\frac{du}{dy}$ is 0. Here also the boundary condition is $\frac{du}{dy}$ is 0.

So, again at y equal to 0, u is 0. At y equal to y_1 , $\frac{du}{dy}$ is 0. At y equal to y_2 , $\frac{du}{dy}$ is 0 and at y equal to d , u is 0. So, these are the boundary conditions that we have to deal with and the fluid model that we would be dealing with is the Bingham plastic model. So, τ is again τ_y multiplied by \sin of $\dot{\gamma}$ plus μ of $\dot{\gamma}$ when the stress is more than the yield stress.

$$\tau = \tau_y \sin(\dot{\gamma}) + \mu \dot{\gamma}$$

So, this is the material model that we will be using. The fluid model and these are the boundary conditions. The governing differential equation remains the same.

So, with this set of condition we have to solve the problem and we will do that in the next lecture.

Thank you.
