Lecture No. # 40
An Overview of Kalman Filter Theory

Hello everyone, we will continue with our last lecture today; and before end of this course, I thought an appropriate topic is some review of Kalman Filter Theory, because without that probably in my view, no control theory is complete. Now obviously, I will not be able to do a justice with all the derivations and everything about Kalman Filter Theory, but I will be able to give you some sort of a summary or a little bit theory round that, so that you can **actually** take this and implement in your problems **actually**. So, let us do that, but before **before** doing that, let us go through a little bit on what we discussed last time. And that was about this LQ observer, that we discussed last time **actually**, so a very quick review of that.

(Refer Slide Time: 01:06)

Why Observers?

- State feedback control designs need the state information for control computation
- In practice all the state variables are not available for feedback. Possible reasons are:
 - Non-availability of sensors
 - Expensive sensors
 - Quality of some sensors may not acceptable due to noise (its an issue in output feedback control design as well)
- A state observer estimates the state variables based on the measurement of some of the variables as well as the plant information

NPTTEL
ADVANCED CONTROL SYSTEM DESIGN
Dr. Radhakant Padhi, AE Dept., IISc-Bangalore

So, **this is** this is what we did this, observers and all we are need, because I mean the need for the observer or estimator is because we typically proposed a feedback control design, and state information is needed for control computation. And most of the time, you may not

have sensor rich systems. In other words either the sensor is not available expensive sensors, all that **actually** whatever we discussed last **last** class.

(Refer Slide Time: 01:29)

Observer Design for Linear Systems

Plant : $\dot{X} = AX + BU$
 $Y = CX$ (sensor output vector)

Let the observed state be \hat{X} and the **Observer dynamics** be

$$\dot{\hat{X}} = \hat{A}\hat{X} + \hat{B}U + K_e(Y - \hat{Y})$$

Error : $\tilde{X} \triangleq (X - \hat{X})$

 ADVANCED CONTROL SYSTEM DESIGN
 Dr. Radhakant Padhi, AE Dept., IISc-Bangalore

So, what we did **did** here, in an observer for linear system design, we have a system plant like that, we propose that observer dynamics we constructed like this, where K is an estimator gain. And then we did discussed about the error, error being X minus X hat, where hat is the estimated information, X is a true information.

(Refer Slide Time: 01:47)

Observer Design for Linear Systems

Error Dynamics: $\dot{\tilde{X}} = \dot{X} - \dot{\hat{X}}$

$$= (AX + BU) - (\hat{A}\hat{X} + \hat{B}U + K_e Y)$$

Add and Subtract $\hat{A}X$ and substitute $Y = CX$

$$\begin{aligned} \dot{\tilde{X}} &= AX - \hat{A}X + \hat{A}X - \hat{A}\hat{X} + BU - \hat{B}U - K_e CX \\ &= (A - \hat{A})X + \hat{A}(X - \hat{X}) + (B - \hat{B})U - K_e CX \\ &= \hat{A}\tilde{X} + (A - \hat{A} - K_e C)X + (B - \hat{B})U \end{aligned}$$

Goals: 1. Make the error dynamics independent of X
 ($\because X$ may be large, even though \tilde{X} may be small)

2. Eliminate the effect of U from error dynamics

NPTEL
 ADVANCED CONTROL SYSTEM DESIGN
 Dr. Radhakant Padhu, AE Dept., IISc-Bangalore

Then what happens is like, you go through this error dynamics and think like that, and try to make sure that, it is not a function of the error dynamics is I mean the \dot{X} tilde dot is not a function of state and control. So, we enforce this coefficient to be 0.

(Refer Slide Time: 02:00)

Observer Design for Linear Systems

This can be done by enforcing $A - \hat{A} - K_e C = 0$
 and $B - \hat{B} = 0$

Necessary and sufficient condition for the existence of K_e :
 The system should be "observable".

This results in $\hat{A} = A - K_e C$
 $\hat{B} = B$

Observer dynamics: $\dot{\hat{X}} = \hat{A}\hat{X} + BU + K_e(Y - C\hat{X})$

NPTEL
 ADVANCED CONTROL SYSTEM DESIGN
 Dr. Radhakant Padhu, AE Dept., IISc-Bangalore

And then we derive this estimated dynamic, observer dynamics to be of this form. So, it is exactly falls into this **this** form that X plus $B U$, but we have an additional term $K e$, that is

estimated gain times, Y that the actual output minus estimated output C X hat **actually**, so that is the innovation term (Refer Slide Time: 02:07). So, you have that filter dynamics as like linear system dynamics plus Kalman gain times, innovation term **actually**.

(Refer Slide Time: 02:28)

Comparison of Control and Observer Design Philosophies

Control Design	Observer Design
<ul style="list-style-type: none"> CL Dynamics $\dot{X} = (A - BK).X$	<ul style="list-style-type: none"> CL Error Dynamics $\dot{\tilde{X}} = \hat{A}\tilde{X} = (A - K_e C).\tilde{X}$
<ul style="list-style-type: none"> Objective $X(t) \rightarrow 0, \text{ as } t \rightarrow \infty$	<ul style="list-style-type: none"> Objective $\tilde{X}(t) \rightarrow 0, \text{ as } t \rightarrow \infty$
	<ul style="list-style-type: none"> Notice that $\lambda(A - K_e C) = \lambda[(A - K_e C)^T] = \lambda(A^T - C^T K_e^T)$

NPTEL
 ADVANCED CONTROL SYSTEM DESIGN
 Dr. Radhakant Padhu, AE Dept., IISc-Bangalore 35

Then we went and saw a comparison between control design, and observer design where you tell the close dynamics of that, for the control system design and like that, and close look error dynamics for the observer, I mean turns out to be very close to that **actually**. When we discussed the objective here is like, X ((O)) go to 0 and that is the keeping that objective, we have designed an ((O)) controller, and objective here is also X tilde should go to 0. So, fairly similar objectives, only problem was K e happens to be in the left hand side here whereas, it happens to be right hand side here.

So, we took transpose of this matrix and while doing the transpose K e transpose turns out to be the right, and then we told **we can** we can **actually** treat this A transpose and C transpose is equivalent A and ((O)). And then design a K e transpose instead **instead** of directly designing K e, you will be able to design K e transpose, but the once you design that then taking transpose means, we have done with the design **actually**.

(Refer Slide Time: 03:21)

Algebraic Riccati Equation (ARE) Based Observer Design

System	Dual System
$\dot{X} = AX + BU$ $Y = CX$	$\dot{Z} = A^T Z + C^T V$ $n = B^T Z$
$M = [B AB \dots A^{n-1}B]$ $N = [C^T A^T C^T \dots A^{n-1} C^T]$	$M = [C^T A^T C^T \dots A^{n-1} C^T]$ $N = [B AB \dots A^{n-1}B]$

LQR Design

$$\dot{X} = -KX$$

ADVANCED CONTROL SYSTEM DESIGN
 Dr. Radhakant Padhi, AE Dept., IISc-Bangalore
 36

So, for that we have this system dynamic original system, and had a dual system, and observe that control availability for one is observability for the other and vice versa.

(Refer Slide Time: 03:32)

ARE Based Observer Design

<p>CL system (control design)</p> $\dot{X} = (A - BK)X$ $X \rightarrow 0 \text{ as } t \rightarrow \infty$ $K = R^{-1}B^T P, \quad P > 0$ <p>where,</p> $PA + A^T P - PBR^{-1}B^T P + Q = 0$	<p>Error Dynamics</p> $\dot{\tilde{X}} = (A - K_e C)\tilde{X}$ $(A - K_e C)^T = A^T - C^T (K_e^T)$ <p>Analogous</p> $K_e^T = R^{-1}CP$ <p>where,</p> $PA^T + AP - PC^T R^{-1}CP = 0$ <p>Observer Dynamics</p> $\dot{X} = AX + BU$
---	--

ADVANCED CONTROL SYSTEM DESIGN
 Dr. Radhakant Padhi, AE Dept., IISc-Bangalore

So, if you see this close looks to system dynamics and all, so we propose that this K_e transpose is should be designed, that is similar to what we design is Kalman **Kalman** gain **actually**, I mean for this, for the control design part of it **(O)**. So, instead of R B transpose T

we should have R inverse C times P ; and this P should be a is like a solution of this matrix, and think like that **actually**.

So, any way, we continued with that and then the observer dynamic turns out to be like this, **with the** with the way to design and observe again **actually**. So, **this is** this is all turns out to be **like a** like the L Q observer design, and then we will say, I mean we have also told that towards the end of the last lecture is like.

(Refer Slide Time: 04:18)

Problem Statement

System Dynamics: $\dot{X} = AX + BU + GW$ $W(t)$: Process noise vector
Measured Output: $Y = CX + V$ $V(t)$: Sensor noise vector

Assumptions:

- (i) $X(0) \sim (\bar{X}_0, P_0)$, $W(t) \sim (0, Q)$ and $V(t) \sim (0, R)$
are "mutually orthogonal" [$X(0)$: initial condition for X]
- (ii) $W(t)$ and $V(t)$ are uncorrelated white noise
- (iii) $E[W(t)W^T(t+\tau)] = Q\delta(\tau)$, $Q \geq 0$ (psdf)
 $E[V(t)V^T(t+\tau)] = R\delta(\tau)$, $R > 0$ (pdf)

 NPTEL

ADVANCED CONTROL SYSTEM DESIGN
Dr. Radhakant Padhi, AE Dept., IISc-Bangalore

39

If you consider the system dynamics with a noise, process noise and sensor noise, then it **then it** also turns out that the filter dynamics and all remain similar, and then that is the little bit more retail will **will** see this, in this class and continue further **actually**. So, this **this** is about this lecture is about Kalman filter theory, so we will revisit that **that** towards the end of the lecture, what we discussed last time, and then continue further **actually**.

(Refer Slide Time: 04:47)

Outline

- Continuous-time Kalman Filter (CKF)
- Discrete-time Kalman Filter (DKF)
- Continuous-Discrete Kalman Filter (CDKF)
- Extended Kalman Filter (EKF)

NPTEL
ADVANCED CONTROL SYSTEM DESIGN
Dr. Radhakant Padhi, AE Dept., IISc-Bangalore

So, outline of this particular lecture, will be something like this, we have continued time Kalman filter, that we talked upon in last class, then we will extend that to discrete time Kalman filter. So, the system dynamics is given in discrete form now, and the measurement is also given in discrete time. Then we will try to combine the (O) discrete Kalman filter; in other words, system dynamics is continuous, because measurements comes at discrete times.

So, that that is what reality is actually most of the time, and this will give us a platform to talk about something called extended Kalman filter, which is used heavily in in practice. Most of the time when people tell I have used the kind of Kalman filter, that is what they mean they have actually implemented and EKF in the into this design basically. So, to up to that, we will discuss in this lecture and then probably that will be about summary, before we wind up this course alright.

So, continuous time Kalman filter design for liner time invariant system, that is the that is the basic starting point and that is what we discussed last class also. So, we we have a system dynamics which is like $\dot{X} = A X + B U + G W$, and then measurement equation turns out to be $Y = C X + V$, where W and V are like, W is process noise vector and V is sensor noise vector. Remember, this these are effecting the system anyway, because the W is nothing but, an input which is directly effecting the system state, and if you

really want to estimate a state into the feedback control design; that means, U becomes estimated for **I mean** function of an estimated state; then for the estimation process you will use Y , and Y is corrupted by sensor noise anyway. So, this two will **will** affect the system dynamic, the effect **I mean** it will affect the performance of the controller like that **actually**. So, if it proceed further there are some **some** of the assumptions involved, and what it means is initial condition of X is given like this, W is given like this, pair Q 0 Q and V is like 0 R , what it means in this parenthesis is, the first thing is mean the second is variance **actually** or there is a vector it is called covariance matrix (Refer Slide Time: 06:48).

So, that means, X of 0 initial condition mean **mean** value is X tilde 0 and the covariance matrix is P naught similarly, W T is **is** a process noise has 0 mean, and Q as the covariance matrix for this, what is the covariance matrix by the way, this is all given here. Expected value of W times W transpose is **actually** Q , if τ is equal to T and **sorry** τ is 0 ; if τ is not 0 then it will happen to be 0 **actually**, because delta function is defined like that any way.

So, this is Q means that expected value of W time, W transpose at the same time basically, that is what it means, anyway so we also assume that this W and V are uncorrelated white noise, that is a fundamental back bone Kalman filter theory, that this noise thing that **that** are accounted for are assume to be white. They may or may not be white, but in the entire theory W of they are assume to be white, and what you mean by white is like there supposed to be like uncorrelated that means, if I take **I mean** the correlation process and all are **are** defined like this.

If I take any **(())** other time like T and T plus τ , τ is a non 0 quantity, then I should be at 0 **actually**, so there is nothing, if I multiply the same process noise with the same point of time, then I will get Q , but if any other time if I multiply then I will get 0 **actually**. So, these are like, **what is** what are called is white noise **actually**, and we also they are assume to be 0 mean **actually**, W and V are assume to be 0 mean **alright**.

(Refer Slide Time: 08:44)

Problem Statement

Objective:

To obtain an estimate of the state vector $\hat{X}(t)$ using the state dynamics as well as a "sequence of measurements" as accurate as possible.

i.e., to make sure that the error $\tilde{X}(t) \triangleq [X(t) - \hat{X}(t)]$ becomes very small (ideally $\tilde{X}(t) \rightarrow 0$) as $t \rightarrow \infty$.

NPTEL
ADVANCED CONTROL SYSTEM DESIGN
Dr. Radhakant Padhi, AE Dept., IISc-Bangalore

So, objective here what is the problem statement, they are the objective here to estimate the state vector $\hat{X}(t)$ using the state dynamics, as well as a sequence of measurement **actually**. We are not talking about only a single measurement, you have to have a sequence of measurement and using all those sequence of measurements, if observability is there that means, **if I mean** if I keep on taking sequence of measurement as a combination **actually**. The sequence of measurements, so **will have** will be effected by system state **actually**, let us the meaning of observability.

Assuming that observability is there, for the system output and system dynamic **(())** that we are talking about, then **what we** what we really talk is, we take sequence of measurements, they are corrupted by noise **alright**, still we will be able to get a good estimate $\hat{X}(t)$. And what do you mean by good estimate, it again means that, if I take $\tilde{X}(t)$ that is error between true and estimated values, that will become very small **I mean I mean** ideally $\tilde{X}(t)$ will go to 0 $\tilde{X}(t) \rightarrow 0$ as $t \rightarrow \infty$. But, **in a** in a stochastic sense, where this noise vector is there and all this will not happen in this **you know**, even though we would like to happen **actually**.

So, **what will** what will happen, then the expected value of $\tilde{X}(t)$ will go to 0, **if I** as I take expected value means, it is large **large I mean** as the average of large number of cases

actually. So, if I keep on **I mean** taking this \hat{X} for a large number of discrete point of time probably, then if I take the mean value of that, and that should go to (0) at least. So, expected value sense it should go to 0; that is all we are demanding **actually**. So, let me probably write it here, what we are telling here is expected value of \hat{X} , so it will go to 0, **that is** that is our objective **actually**, totally speaking **alright**.

(Refer Slide Time: 10:47)

Observer/Estimator/Filter Dynamics

$$\dot{\hat{X}} = A\hat{X} + BU + K_e(Y - \hat{Y})$$

where (i) $\hat{X} = E(X)$: Estimate of the state X
(ii) $\hat{Y} = E(Y)$: Estimate of the output Y
 $= E(CX + V)$
 $= E(CX) + E(V)$
 $= CE(X) \quad (\because E(V) = 0)$
 $= C\hat{X}$
(iii) K_e : Estimator/Filter/Kalman Gain

Problem : How to design K_e ?

NPTEL
ADVANCED CONTROL SYSTEM DESIGN
Dr. Radhakant Padhi, AE Dept., IISc-Bangalore

So, **let us** let us see that, how does it happen, **we will** we will get motivated by this L Q observer, that we discussed last class and all. And take K, we will assume the same observer dynamics rather; **it is** it is not similarly, it is same **actually**. So, we will just take a \hat{X} plus B U plus gain times estimated gain times Y minus Y hat, where Y hat is estimated output, and estimated output will turn out to be C X hat again **actually**.

So, this derivation is fairly straight forward, because see Y **I mean**, X hat by definition is expected value of X, what you mean by X hat, here is not **I mean** this X hat is nothing but, expected value of (No audio from 11:36 to 11:46) (Refer Slide Time: 11:25) **this X** this X hat is nothing but, expected value of X **actually**. So, in that sense the Y, if you continue with Y hat, and Y hat is expected value of Y and Y is nothing but, C X plus V and I get property of that expectation operation **is it** is a linear operator. So, we will be able to split it out and take C out of this operation.

So, it turns out to be expected value of V is anyway 0, because it is 0 mean white noise. So, this is, because of that the expected value of V turns out to be 0, and expected value of X is except by definition. So, \hat{Y} turns out to be $C \hat{X}$, and that is how it will operate **actually**, now the problem is **how do you** how do you come up with this design of K_e . So, this is what **what** is required anyway, without that we will not be able to propagate the system dynamic **actually**. So, we will not go through the entire derivation, **I mean it** it will require probably a full class and all that.

(Refer Slide Time: 13:00)

Solution: Summary

- (i) Initialize $\hat{X}(0)$
- (ii) Solve for Riccati matrix P from the Filter ARE:

$$AP + PA^T - PC^T R^{-1} CP + GQG^T = 0$$
- (iii) Compute Kalman Gain:

$$K_e = PC^T R^{-1}$$
- (iv) Propagate the Filter dynamics:

$$\dot{\hat{X}} = A\hat{X} + BU + K_e(Y - C\hat{X})$$

where Y is the measurement vector

NPTEL
 ADVANCED CONTROL SYSTEM DESIGN
 Dr. Radhakant Padhi, AE Dept., IISc-Bangalore

So, **what we what we** what I will tell is just a summary part of it, and summary part is like the gain, what we are talking about here, Kalman gain can be computed like this, $P C$ transpose R inverse, and then $P C$ transpose T inverse, this **(())** that after you compute this, then \hat{X} hat dot is nothing but, $A \hat{X}$ hat plus $B U$ plus K_e times Y minus $C \hat{X}$ hat **actually**. So, what do you compute this P , P is given like you can solve this Riccati equation, it is called filter Riccati equation **actually**.

And if you see this Riccati equation, **I mean** before what we discussed, so the only difference is probably this term **actually**. So, this term I mean the $L Q$ observation same this **this** term, earlier you did not have a G in the left, G transpose in the right **actually**, it was

only Q (Refer Slide Time: 13:42). So, if you assume that G is **actually**, like a identity matrix here or $G W$ is the noise, not **not** W parse, then it is nothing but, an $L Q$ observer **actually**.

In other words, $L Q$ observer is also like a Kalman filter, where you are assuming that that G is **actually** identity matrix, may not happen of course, I mean the W , may not W is like a control input, control input may not alter the \dot{X} directly with V ; it passes through a influence matrix anyway G , it is like a V matrix. So, if you assume that G is **actually** identity then it is nothing but, **(())** $L Q$ observer **actually**, anyway so **this is** this is how it operate, so if you really want to mechanize a Kalman filter like this, all that you have to do is initialize $\hat{X}(0)$ with the guess. Then you have to solve this Riccati matrix P for the filter algebraic Riccati equation, because this is **in the** in the framework of infinite time that means, it may take a little longer time to stabilize **actually**, if your $T F$ is infinity, then this is 0 otherwise, it will not be **actually** 0.

Anyway assuming that it is, if this algebraic equation, Riccati equation is solved this is called filter Riccati equation, and then this after we solve for P , we compute the Kalman gain that something like this, and once you are there then you can propagate the system dynamic. Because, you have already have an initial condition there, and that it will also lead to this good stability behaviour, and think like that means, the error that we are talking about \tilde{X} , which is expected value of \tilde{X} and all that what we discussed here, it is all guaranteed to happen **actually**, because, it is a linear time invariance system.

And there are also nice property such as, in the sense of this is of something called separation principle and all, so that means, you can design a controller and of the estimator separately each other. So, it **it** will not have the stability behaviour, each of the thing even though, you want to operate it based on the feedback system, **I mean** if you want to operate U based on a feedback of estimated state, then all nothing is going to happen drastically wrong, basically.

Because, the close loops Eigen values, will be Eigen values of this system **I mean** and the Eigen values of error dynamics and all that. So, those theorems are, there I will not discuss too much on that **actually**. So, this is the summary of how do you mechanize a continuous time Kalman filter. But, that is not the problem here is it, this **this** entire formulation,

assumes a continuous availability of measurement Y is $C X$ plus V ; that means, continuously the measurement is **is** coming to us **actually**.

And suddenly, that is not reality; measurements are taken only a discrete point of time **actually**. So, **if if** that is the case then it also makes sense to probably discretise, this system equation, system dynamic equation; and we have several methods, any way we can use 0 order either integration also the thing. I mean what about **(())** method. So, once you **(())** the system dynamic, and the measurement is anyway coming in **in** discrete manner; then probably we will have a compatible system to talk about **actually**. So, that is what this discrete time Kalman filter theory talks about.

(Refer Slide Time: 17:12)

Model:

$$X_{k+1} = A_k X_k + B_k U_k + G_k W_k$$

$$Y_k = C_k X_k + V_k$$

where W_k and V_k are zero-mean,
uncorrelated, Gaussian white noises

$$E[W_k W_j^T] = Q_k \delta_{kj}$$

$$E[V_k V_j^T] = R_k \delta_{kj}$$

$$E[V_k W_k^T] = 0 \quad \forall k$$

$$\delta_{kj} = \begin{cases} 0 & k \neq j \\ 1 & k = j \end{cases}$$

NPTEL
ADVANCED CONTROL SYSTEM DESIGN
Dr. Radhakant Padhi, AE Dept., IISc-Bangalore

So, **let us** let us talk about that, so what we are assuming here is as a discrete time system model, again linear time linear system, and when you talk about discrete time system normally, there is no difference rather you take like time varying system or time invariant system, so we will just take time varying system **actually**. So, X_{k+1} is $A_k X_k$ plus $B_k U_k$ plus G_k times W_k Y_k $C_k X_k$ plus V_k , so remember A_k , B_k , C_k , G_k all that they are then is not necessarily be constant, they can be also the time getting **actually**.

Again we assume that, W_k and V_k are 0 mean uncorrelated Gaussian white noises, **this is a** these are like little bit strong assumption, but then these are standard assumption for Kalman filter theory. So, this they **they** are corrupted by noise **alright**, but the noise that is this property, both of the noise have 0 mean, they are uncorrelated and the Gaussian process is also **(0)**, Gaussian makes it probability the assumption of Gaussian **(0)** I mean done to both address realistic situation. That most of the time, then as happens to be Gaussian, and once you assume Gaussian noise there **there** is lot of nice properties **actually**, for which thus the theory becomes complete.

For example, if you if you have a Gaussian distribution then mean and variance gives us the entire meaning, I mean more than that there is nothing **actually**. So, if once you know the noise is **actually** Gaussian, and once you know the mean and it is variance, then we are probability done **actually**, theory we complete easily. But, for entire derivation remember, I mean in my view all that is required is that it has 0 mean non correlated thing, so 0 mean white noise that is all we need **actually** for the derivation part. So, let us proceed with that, then because of this assumptions, **these are** these are all good and what it means is if I take expected value of W times W transpose, if they are not taken at the same instant of time that is 0, nothing happens there.

If they are taken at the same instant of time, then this and this Q_k matrix and this Q_k is called process noise covariance matrix, **actually**. Similarly, if you take sensor noise covariance matrix, that is the relationship between **(0)**, so if they are not taken at the same time that is 0, if they are taken at the same time then this and these are connected, is R_k matrix. And if you take even at the same time, what about different time between V and W , then it is 0, so they are totally uncorrelated to each other **actually**.

It is either auto correlated autocorrelation sense self correlation sense **that** that happens, that way, but if you take cross correlation sense V_k , W_k like two different things, I can together on that no matter, what about time we are talking about they are all 0 **actually**. So, these are like, if you think that is slightly strong essences rather, there are also tricks and techniques to is not really a white noise, **how do you** how do you make use of it there are ideas like say

filter design like, you can situate some sort of a small system, sub system rather, where **where** you take white noise input.

And output of that artificial sub system should be really the colour noise that we are talking about actually; then you can argument the original system dynamic with that artificial system, which will like in filter design and all. Then **then** you can talk about estimating the entire state vector actually, so those **(0)** summary is interested they are encouraged to study details of those anyway, filter theory is a fascinating subject it is a complete theory by itself and all that **actually**. So, there are many tricks and techniques available on the various **actually**.

(Refer Slide Time: 20:53)

Estimator: (Predictor-Corrector form)

Predictor: $\hat{X}_{k+1}^- = A_k \hat{X}_k^+ + B_k U_k$ (1)

Corrector: $\hat{X}_k^+ = \hat{X}_k^- + K_{ek} [Y_k - C_k \hat{X}_k^-]$ (2)

Observer (Recursive) form:
Substituting (2) in (1)

$$\hat{X}_{k+1}^- = A_k \hat{X}_k^- + B_k U_k + A_k K_{ek} [Y_k - C_k \hat{X}_k^-]$$

Note: Prediction-Correction form is more popular since its logic is more structured and easy to implement form. It also leads to a logical extension in Extended Kalman Filter.

NPTEL
ADVANCED CONTROL SYSTEM DESIGN
Dr. Radhakant Padhi, AE Dept., IISc-Bangalore

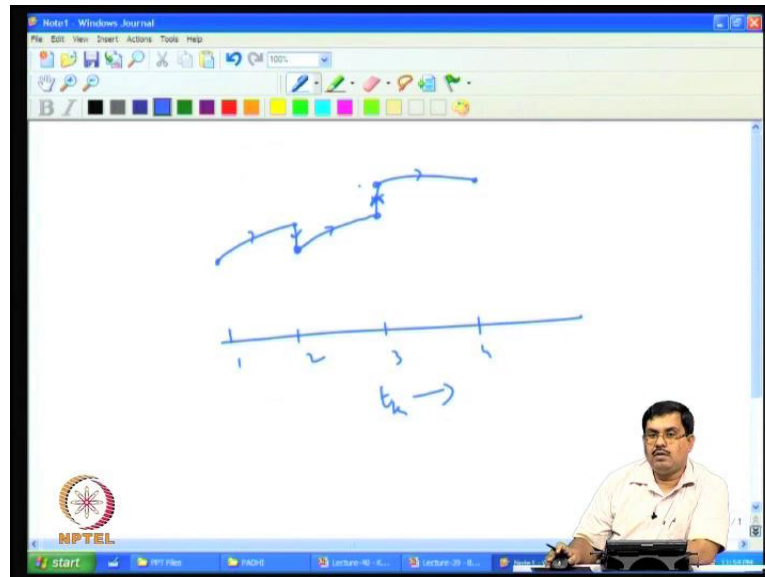

Anyway, so going back this is **what you** what is assumed, now **what is our I mean** what is the way to proceed further, so we need some sort of a filter dynamics anyway. And the filter dynamics is an artificial system dynamics, which simply needs to be propagated, with some initial condition and some then computation **actually**. So, there are two ways of doing this here, and the discrete time, one is like I will assume **it is a** it is a predictor corrector form, which is **actually** very popular.

There are several reasons for that of course, and then there is an observer form **what you have this** what you have seen in the, this continuous time framework, so observer form or recursive form can be derived from this. So, for **I mean** this from the predictor corrector form easily actually rather, anyway what you are doing here first of all you predict for the next time state; let us talk about this, let us assume that I know some state information already, at k the instant of time and I also know the controller at k the instant of time.

So, **I will be able to** I will be able to take advantage of this system dynamics, without the noise of course, and then I will be able to predict what is going on **actually** that means, if the noise does not happen to be there, then I should have a better prediction here. Whatever I am predicting here, but remember this prediction part assume any **any** sensor information **actually**, and once the sensor information is there that means, sensor has given me some value; I will be able to update this value from **from** that k plus 1 time (t) . And same thing happens in T the instant of time also, if I start with k minus 1, then **I this** I will get k **actually** here, and then k will be updated here. So, first prediction, then update, prediction update like, that it will happen **actually**. Now, if you the reason it is written here (t) k plus 1, but k is easy to see, that if I put substitute this **this** expression here, then I will be able to derive this **actually**; this is this is observer form or or recursive form **actually**. So, prediction correction form is more popular since, it is more logical structured way, and easy to implement also **actually**, we will see that **actually**.

They also leads to a logical **logical** extension, extended Kalman theory, **which is** which is primary requirement (t) ; if (t) once have definitions remember, we are talking about plus minus plus minus all sort of things here. So, we will be able to do some of these **actually** anyway, so before we proceed further, this in this let me explain a little bit here **it is ok**.

(Refer Slide Time: 23:46)

So, what we are telling here is something like, we have this time sequence of k this is 1, this 2, this is 3 like that, well we have this picture one more time alter anyway. So, I start with some information here, and then I will be able to predict using the system dynamic that I know, from step one to step two this is that time exist **actually**. Then **when I** when I have this measurement information coming then, I will update this here, then I will again predict it here from two to three, I will get some value, then I will be able to update using **using** some sort of sensor information, then I will continue that.

So, this is that the prediction part and then there is a correction part **actually** involved, so this is this is the correction part **sorry** this is, **this is** this way. So, predict correct, predict correct like that it will happen **actually**, so this that is the meaning of that alright, so let us continue this.

(Refer Slide Time: 24:44)

Definitions

Error

$$\tilde{X}_k^- \triangleq X_k - \hat{X}_k^- \quad \tilde{X}_{k+1}^- \triangleq X_{k+1} - \hat{X}_{k+1}^-$$

$$\tilde{X}_k^+ \triangleq X_k - \hat{X}_k^+ \quad \tilde{X}_{k+1}^+ \triangleq X_{k+1} - \hat{X}_{k+1}^+$$

Error Covariance Matrices

$$P_k^- \triangleq E[\tilde{X}_k^- \tilde{X}_k^{-T}] \quad P_{k+1}^- \triangleq E[\tilde{X}_{k+1}^- \tilde{X}_{k+1}^{-T}]$$

$$P_k^+ \triangleq E[\tilde{X}_k^+ \tilde{X}_k^{+T}] \quad P_{k+1}^+ \triangleq E[\tilde{X}_{k+1}^+ \tilde{X}_{k+1}^{+T}]$$

Objective: To derive expressions for P_{k+1}^- .

MPTEL
ADVANCED CONTROL SYSTEM DESIGN
Dr. Radhakant Padhi, AE Dept., IISc-Bangalore

So, before **before** proceeding further let us talk about certain **certain** error values, and all that, so remember I have so, the prediction part is **is** written normally like minus, and the correction part is written as plus **actually**. So, when you see minus that means, it is **actually** coming from the prediction, when you see plus, it is **actually** corrected taking the output information **actually**, so prediction part and then correction part like that.

So, **I mean** we will define this **this** error quantities, this error covariance matrices and think like that before proceeding further. So, this X tilde minus X tilde k minus is nothing, but X k minus X k hat minus similarly, X tilde k plus is X k minus X hat k plus and similarly, k plus 1 and think like that. Now, error covariance matrix, it we also needs to define, **I mean** we need to define at this way P k minus that is the error covariance matrix at time step k, in the prediction part of it, is given like this, expected value of X tilde k minus times X tilde k minus transpose like that.

They are all outer product anyway, because it so each of that is **(0)** vector, so if I get an outer product, it becomes like **(0)** matrix basically. So, **this error** this error values are error states are defined like that, and error covariance matrices are defined like that, they are simply definition to **(0)**. And obviously, objective here is to derive expressions for this **actually**, we ultimately need to derive expressions for Kalman gain, $K E k$, but also we need

to derive this expression, P_{k+1} minus P_k because, $k E k$ is a function of this. So, we need to derive expressions for that **actually**, and we cannot really start with the definitions, because this is expected value means **we have to** we should have **I mean** infinite number of this **I mean** values available to us.

And then we have to take average value of that and all, so from definition **it will not be** it is not advisable, it is not possible also. We need a kind of precise information like; separate expressions to derive this **actually**, so **let us do** let us see whether we can do that. Now, expressions for P_{k+1} minus, so remember P_{k+1} minus is **is** given like this, so we need to derive an expression for that one first, and then type the expected value of this outer product and all that.

(Refer Slide Time: 27:12)

Expression for P_{k+1}^-

$$\begin{aligned} \tilde{X}_{k+1}^- &= X_{k+1} - \hat{X}_{k+1}^- \\ &= (A_k X_k + B_k U_k + G_k W_k) - (A_k \hat{X}_k^+ + B_k U_k) \\ &= A_k (X_k - \hat{X}_k^+) + G_k W_k \\ &= A_k \tilde{X}_k^+ + G_k W_k \end{aligned}$$

NPTEL
ADVANCED CONTROL SYSTEM DESIGN
Dr. Radhakant Padhi, AE Dept., IISc-Bangalore

So, what is this, this is by definition is this two and then this **this** X_{k+1} is like this, then this **this** part is given like that from the definition, this is coming from this **actually**. So, this **this** part can from that, and then this part is nothing but, the system dynamic remember, estimated 1 is the known wise, but the true one is given with noise anyway. So, now we see that these two are **are** cancelled out, and this **this** $B_k U_k$, will go from $B_k U_k$ and you are left out with only the rest of the terms; and that is given something like this, so if I see X_{k+1}^- it turns out to be like that.

(Refer Slide Time: 28:01)

Expression for P_{k+1}^-

$$P_{k+1}^- = E[\tilde{X}_{k+1}^- \tilde{X}_{k+1}^{-T}]$$

$$= E[(A_k \tilde{X}_k^+ + G_k W_k)(A_k \tilde{X}_k^+ + G_k W_k)^T]$$

$$= E[A_k \tilde{X}_k^+ \tilde{X}_k^{+T} A_k^T + G_k W_k \tilde{X}_k^{+T} A_k^T + A_k \tilde{X}_k^+ W_k^T G_k^T + G_k W_k W_k^T G_k^T]$$

$$= A_k E[\tilde{X}_k^+ \tilde{X}_k^{+T}] A_k^T + G_k E[W_k \tilde{X}_k^{+T}] A_k^T$$

$$+ A_k E[\tilde{X}_k^+ W_k^T] G_k^T + G_k E[W_k W_k^T] G_k^T$$

$P_{k+1}^- = A_k P_k^+ A_k^T + G_k Q_k G_k^T$ $P_0^- = E[\tilde{X}_0^- \tilde{X}_0^{-T}]$

Note: Only \tilde{X}_{k+1}^- depends on W_k , not \tilde{X}_k^+ ; i.e. \tilde{X}_k^+ and W_k are "orthogonal".

MPTEL
ADVANCED CONTROL SYSTEM DESIGN
Dr. Radhakant Padhu, AE Dept., IISc-Bangalore

So, now, I can take P_{k+1}^- which is expected value of this **this** times the transpose, and this one I have just derived, this is like this, so I will take a transpose of that also, then **I will** I will expand this transpose and then multiply to the do the algebra and all that **actually**. And remember, these are all like cross correlation is 0, so expected value of this W_k and X_k tilde k this is 0, and this is also 0 anywhere, we see a across correlation term, these are all 0 by assumption in Kalman filter theory.

So, it take **(0)** out those and we are left out with these, and these values remember whatever you have here this is nothing but, **definition** if you go back to definition this turns out to be like that, so this is nothing but, P_{k+1}^- **actually right**. So, this **this** one what you see here is nothing but, P_{k+1}^- , so what you what you have here A_k times P_{k+1}^- times A_k transpose **(0)**.

(0) simply like good book keeping basically, if you know what you are doing substitute, expand and then cancel out put something, **I mean** C wise all times 0 and deal with rest of the term that are left out **actually**. Similarly, if you see this one, expected value of W_k times W_k transpose, that happens to be Q_k by definition, and then it turns out to be like that **actually**.

So, if you really want P_{k+1} , then it is a function of P_k and think like that **actually**. So, this happens to be because, this W_k and X_k these are like what is called as an orthogonal, orthogonal means this expected value of that happens to be 0. So, this process will start **start** from P_0 , and P_0 is like initial covariance matrix of this error vector and all that, and that is supposed to be a selected by the design basically. That is how you start with along with your \hat{X} information, like guess for the initial condition for the estimated state; you also start with a guess for your covariance matrix **actually**.

(Refer Slide Time: 30:06)

Expression for P_k^+

$$\begin{aligned}
 \tilde{X}_k^+ &= X_k - \hat{X}_k^+ \\
 &= X_k - \left[\hat{X}_k^- + K_{e_k} (Y_k - C_k \hat{X}_k^-) \right] \\
 &= X_k - \left[\hat{X}_k^- + K_{e_k} (C_k X_k + V_k - C_k \hat{X}_k^-) \right] \\
 &= (I - K_{e_k} C_k) X_k - (I - K_{e_k} C_k) \hat{X}_k^- - K_{e_k} V_k \\
 &= (I - K_{e_k} C_k) (\tilde{X}_k^-) - K_{e_k} V_k
 \end{aligned}$$

$$\tilde{X}_k^+ = (I - K_{e_k} C_k) \tilde{X}_k^- - K_{e_k} V_k$$

ADVANCED CONTROL SYSTEM DESIGN
Dr. Radhakant Padli, AE Dept., IISc-Bangalore

14

So, this expression is derived like that, what about the other one that P_{k+1} remember P_k plus is required here, so we need that, so P_{k+1} is by definition is expected value of X_k **I mean**, $\tilde{X}_k^+ \tilde{X}_k^{+T}$. So, we need to have \tilde{X}_k^+ first, so this one is given like this by definition, and **actually** that P_{k+1} is given by this, this is the predictor corrector form, so this is this expression comes there.

So, if you put this **this** expression this, this part here and then try to simplify this it turns out, that I can probably simplify that way **actually**, so I will combine this X_k term is here this X_k term is here, so this is $I - K_{e_k} C_k$ times X_k (Refer Slide Time: 30:36). And similarly, I have this \hat{X}_k^- here and \hat{X}_k^- here, so I will put it there **actually** that way. So, I will try to simplify this, and I got some sort of a formula like that, so

P_k plus is expected value of this expression times that, so I will put this one times that that transpose.

And then again do the same thing, it will expand this **this** bracketed term, and then multiply and see, what all in equation then I can do. So, it turns out that again this expected value of this, these are constant mean these are like expected value is not a function that, so I will be able to take out and these are orthogonal to each other, so they will go. So, what are left out, these two expressions see this **(0)** told here is this two expressions will not be required, so first and last will be there **actually** (Refer Slide Time: 31:31). And first and last by definition will **will** turn out to this part, by definition is P_k minus and this part by definition is **actually**, R_k anyway, so P_k plus happens to be like this.

(Refer Slide Time: 31:50)

Expression for K_{e_k} : Problem

Select K_{e_k} such that $Tr(P_k^+)$ is minimized.

i.e. Minimize $J = \frac{1}{2} Tr(P_k^+)$

with proper selection of K_{e_k}

NPTTEL

ADVANCED CONTROL SYSTEM DESIGN
Dr. Radhakant Padhi, AE Dept., IISc-Bangal

So, now we need to derive A_k , E_k like that estimated problem remember, what is our power problem **actually**, **I mean** the problem here is the P_k plus which by definition, will go back to P_k plus is error times, the error basically, the transpose of course. And this is after update that means, this **this** if you see X_k tilde plus, this is after this X_k hat plus that means, after I correct this using this innovation terms and all that whatever, I get is that and then error term happens to be true minus that.

So, obviously, if I take a kind of a covariance matrix for that, I want that to be minimum **actually**, as minimum as possible ideally 0. So, what I formulated problem is let me go back and try to see, whether I can minimize this **this** operator, **I mean** this P k plus and minimizing this P k plus means, **I** one of that is like trace operator remember this is a P k plus is a matrix.

So, trace is nothing but, kind of a norm operator and the trace is like, **if you I mean** if you see that a little bit that is individual terms, so will happen to be in diagonal, and trace is nothing but, summation of diagonals **actually**. So, if I just take this expression P k plus happens to be like this **this** one, and **(())** if I take second norm square of this **this X tilde plus X tilde k plus second norm square** and that is nothing but, trace of P k plus **actually**.

So, **the** I want to minimize this expression half of trace of P k plus, so whatever happens, whatever the solution I will get is K e k basically. So, how do I how do I do that, if I really want to minimize this J, the necessary condition is J remember, this J happens to be the function of K e k; where P k plus there is a K e k expression and all (Refer Slide Time: 33:35). So, I consider this as a function of K e k, and then try to minimize that **actually**.

(Refer Slide Time: 33:49)

Expression for K_{e_k} : Solution

$$\frac{\partial J}{\partial K_{e_k}} = 0$$

$$(I - K_{e_k} C_k) P_k^- C_k^T + K_{e_k} R_k = 0$$

$$K_{e_k} [C_k P_k^- C_k^T + R_k] = P_k^- C_k^T$$

$$K_{e_k} = P_k^- C_k^T [C_k P_k^- C_k^T + R_k]^{-1}$$

NPTEL
ADVANCED CONTROL SYSTEM DESIGN
Dr. Radhakant Padhi, AE Dept., IISc-Bangalore

So, how do I mean do that, the necessary condition turns out to be like that, and J is this, where P_k plus is this expression anyway. So, I substitute that, and then try to I mean take this also do this algebra, I turns out to be like this, and K_{e_k} happens to be left hand side of both, so I will be able to take common out of that. And then I will solve for K_{e_k} is like this. If I write multiply with this inverse, this this side we will get K_{e_k} this side we will happen like that.

So, K_{e_k} which is Kalman gain in discrete time formulation turn out to be like this actually; we have also an idea that K_{e_k} as what we derived here, one it seems slightly complicated, one does not have to live with that, you can actually simplify this expression, you can expand this with thing, and then cancel out a few terms and it turn out to be as simple as that. But later we will see that this form is advisable because of numerical condition is conditioning is used and all that.

Now, this is like a quadratic form what you see here, so the symmatricity of P_k will not be compromise even for even, because of numerical inaccuracy, same computation and all that. So, even though it is a slightly little more kind of computation, we still I mean we still advisable to use the $(())$ expression anyway.

(Refer Slide Time: 35:04)

Summary

Model	$X_{k+1} = A_k X_k + B_k U_k + G_k W_k$ $Y_k = C_k X_k + V_k$
Initialization	$\hat{X}(t_0) = \hat{X}_0^-$ $P_0^- = E[\tilde{X}_0^- \tilde{X}_0^{-T}]$
Gain Computation	$K_{e_k} = P_k^- C_k^T [C_k P_k^- C_k^T + R_k]^{-1}$

ADVANCED CONTROL SYSTEM DESIGN

Dr. Radhakant Padhi, AE Dept., IISc-Bangalore

So, as the summary **summary** is problem is like this, I have a have a discrete time formulation, where X_{k+1} is like this Y_k is like that, where W and V_k W_k and V_k are uncorrelated, white noise 0 mean orthogonal to state vector all that is there. And then we start this process by initializing this two, we initialize the estimated value of the state as well as, a guess value for the error covariance matrix.

(Refer Slide Time: 35:37)

Summary

Update	$\hat{X}_k^+ = \hat{X}_k^- + K_{e_k} [Y_k - C_k \hat{X}_k^-]$ $P_k^+ = (I - K_{e_k} C_k) P_k^- (I - K_{e_k} C_k)^T + K_{e_k} R_k K_{e_k}^T$ <p style="text-align: center;">(preferable)</p> $= (I - K_{e_k} C_k) P_k^- \quad \text{(not preferable)}$
Propagation	$\hat{X}_{k+1}^- = A_k \hat{X}_k^+ + B_k U_k$ $P_{k+1}^- = A_k P_k^+ A_k^T + G_k Q_k G_k^T$

NPTEL
 ADVANCED CONTROL SYSTEM DESIGN
 Dr. Radhakant Padhu, AE Dept., IISc-Bangalore

Then the gain computation can be done this way, where V_k minus can be computed **I mean** using this **this** propagation equation and all that **actually**. **This is** this is what you see here is nothing but, propagation equation, basically what you see here that means, if I know P_k minus **I will** I will be able to compute P_k plus provided I know K_{e_k} . So, this is the **I mean**, if I have an initial condition I will be able to propagate this covariance matrix anyway, so this is what is going on here.

So, we are initialization which is done, then gain can be computed like this and update equations will proceed that way, so this is after get a measurement, and I will update the state vector that way. So, it is my propagated thing, that the prediction part of it plus the correction term which is coming from the measurement multiplied with a Kalman gain term **actually**.

And then there are covariance matrix can be propagated this way or that way, but this is preferable anyway, so we propagate that and get ready for the next time state **actually**. So, after we are done with this, then we predict it again one more time state, so both state as well as covariance matrix. So, this is because of this easy of implementation is logical flow of the equations and all that, this discrete form is kind of very popular **actually**, predictor corrector form is **is** a natural way of implementation **actually**.

Now, we will move further, and then tell we have obviously, we have seen continuous time Kalman filter we have seen discrete time Kalman filter; neither of that is **actually** a very good reality, because what happens is in pure continuous time Kalman filter the assumption is the sensor noise, **I mean** sensor measurement is **is** available in a continuous time manner, which is not realistic. And may appear discrete form the system dynamic needs to be written in a discrete form, which is approximation to reality. So, I do not know **I mean** this given a choice will like to work with a continuous time state equation, but discrete time measurement equation; and that is where it will lead to continuous discrete gamma filter.

(Refer Slide Time: 37:47)

Continuous-Discrete KF

Continuous time model and discrete time measurements

$$\dot{X}(t) = A(t)X(t) + B(t)U(t) + G(t)W(t)$$

$$Y_k = C_k X_k + V_k$$

$$E[W(t)W^T(\tau)] = Q_k \delta(t - \tau)$$

$$E[V_k V_j^T] = R_k \delta_{kj}$$

$$\delta_{kj} = \begin{cases} 0 & k \neq j \\ 1 & k = j \end{cases}$$

NPTL

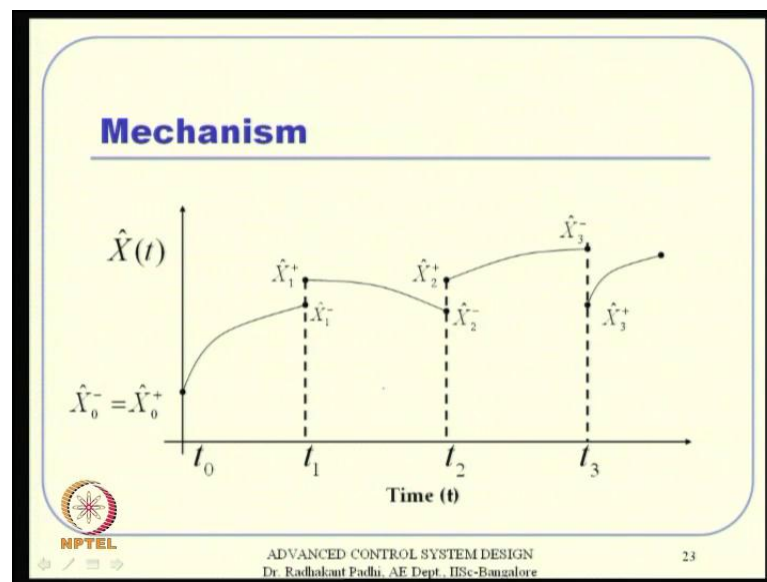

ADVANCED CONTROL SYSTEM DESIGN
Dr. Radhakant Padhi, AE Dept., IISc-Bangalore

So, let us see that in brief, so what you are talking here is the state equation is **is** given in the in terms of continuous time, still it is linear, but now let us talk about time varying system dynamics and all. And the measurement equation is given in terms of discrete time, that is in

W T is continue versus, and V k is discrete sensor noise **actually**. So, they also satisfies this similar properties, and then remember one will say satisfy **(())** the delta sin, and other one is derived delta, this is derived delta this is kind of delta.

So, that means, as long as your T is not equal to tau **this is** this is 0, if T equal to tau this is 1, and similarly if you k is not equal to 0, then it is 0 and if it is equal to 0 this is 1, that is that way (Refer Slide Time: 38:29). So, this is done because, it is a discrete **I mean**, this is a continuous time formulation and this is done, because it is a discrete time formulation. So, probably this, there is a small mistake out this k is not equal to **(())**.

(Refer Slide Time: 38:55)

And this is what I was talking earlier, this is the discrete **I mean**, this prediction correction mechanism is what is popular here, and so assuming some values are T 0, we will be able to predict in a fairly continuous time manner, using any numerical scheme not necessarily 0 out of think like that; you can you can just use any continuous time propagation iterations and all to predict this. So, once you predicted, then the sensor information is available **I will** I will be able to correct it, I will **I mean**, because the sensor will give you assuming **that** that is, that will give me correct information and all that.

I will be able to make take the advantage of that, and then tell I have already given here what let me not operate further on that, and let me correct myself a little there and then operate further. So, this is prediction, this is correction, again prediction, because in between I do not have any sensor information, I have to simply rely on what I have, so starting with this initial condition, I will be able to predict (Refer Slide Time: 39:43). (O) sensor information again, so let me correct again from here, so like that it will proceed **actually**.

(Refer Slide Time: 40:01)

Principle

Propagate the state-estimate model forward from t_k to t_{k+1} using the initial condition \hat{X}_k^+ i.e., $\hat{X}_k^+ \rightarrow \hat{X}_{k+1}^-$

Correct the value \hat{X}_{k+1}^- to \hat{X}_{k+1}^+ using the measurement vector Y_{k+1}

Measurement is available only at discrete time-steps. Hence, the continuum time propagation model DOES NOT involve measurement information. This leads to:

$$\dot{P}(t) = AP + PA^T + GQG^T$$

NPTEL
 ADVANCED CONTROL SYSTEM DESIGN
 Dr. Radhakant Padhu, AE Dept., IISc-Bangalore

So, in principle, it is similar to what you have seen before, so what it tells is propagate the state estimate model forward from T_k to $T_k + 1$ using the initial condition, and correct the information at one of the measurement is available as far I told you before. So, what it runs out is that, unlike this continuous time Kalman filter for expressions and all, because the measurement is not available **in between** in between measurement is simply not this. It turns out that the covariance matrix which is **actually** a continuous time expression, this time is given in a simplified form that that non-linear term, what you had earlier is not there basically.

(Refer Slide Time: 40:50)

Expression for \dot{P}

$$\dot{X} = AX + BU + GW$$

$$\dot{\hat{X}} = A\hat{X} + BU$$

⇒

$$\dot{\tilde{X}} = \dot{X} - \dot{\hat{X}}$$

$$= A\tilde{X} + GW$$

$$\tilde{X}(t) = \varphi(t, t_0)\tilde{X}_0 + \int_0^t \varphi(t, \tau)G(\tau)W(\tau) d\tau$$

$$R_{W\tilde{X}} = E \left[\int_0^t W(t) W^T(\tau) G(\tau) \varphi(t, \tau) d\tau \right]$$

$$= \int_0^t Q \delta(t - \tau) G^T(\tau) \varphi(t, \tau) d\tau = \frac{1}{2} Q$$

 ADVANCED CONTROL SYSTEM DESIGN
 Dr. Radhakant Padhu, AE Dept., IISc-Bangalore

So, this can we derive fairly rather easily, **actually** if you see this expression for P dot this X dot is given like that, X hat is given like that, X hat dot is a prediction part and remember that there is no noise in that **actually**. So, now, if I see that the error definition, and error dynamics and think like that X tilde are X minus X hat, so X tilde dot is X dot minus X hat dot. Because, I just take difference between that to B U B U goes and **I left** I am left out with A times X minus X hat which is X tilde plus G W **actually**. So, I will be able to operate based on this X tilde dot is A X tilde plus G W.

So, remember this time varying system dynamics and time varying system dynamics with W being the input matrix and think like that, I will be able to write the solution of that in a continuous time manner. Where this phi T 0 happens to be like a state transition matrix and think like that, and then R W X tilde, now is X tilde is available. So, covariance matrix for R W tilde will be given something like this, carryout the expression simplified by simplify that and between and thing like that **we will left** we will be left out with this **this** expression really.

(Refer Slide Time: 42:01)

Expression for \dot{P}

$$\dot{P} = E[\dot{X} \tilde{X}^T + \tilde{X} \dot{X}^T] = E[\dot{X} \tilde{X}^T] + \left(E[\dot{X} \tilde{X}^T]\right)^T$$

$$E[\dot{X} \tilde{X}^T] = E[(A\tilde{X} + GW)\tilde{X}^T]$$

$$= AE[\tilde{X} \tilde{X}^T] + GE[W \tilde{X}^T]$$

$$= AP + \frac{1}{2}GQG^T$$

$$\dot{P} = (AP + \frac{1}{2}GQG^T) + (AP + \frac{1}{2}GQG^T)^T$$

$$\dot{P} = AP + PA^T + GQG^T$$

NPTEL
ADVANCED CONTROL SYSTEM DESIGN
Dr. Radhakant Padhu, AE Dept., IISc-Bangalore
26

Now, what you do now, P dot is **is** by definition like this **this** two terms, so we have one term and the same term transpose, and one term we have we need to derive. So, this one term is **is** can be derived simply by definition, with X tilde dot we just derive here, so you put it there, and X tilde is we keep it, then we proceed further like that way; and then at E times expected value of X, see E times expected value of X tilde times X tilde transpose this by definition is P matrix **anyway**. So, we will put P matrix here than this one we just derived it the half times Q C transpose and then G is already there here, so this is half time Q C transpose, so that will happen to be like that. So, P dot is this expression plus the same expression transpose, so this expression what you have here plus the same expression transpose.

Now, you are simplify these two terms, and half **half** will be combined together think like that, so P dot happens to be like that basically, that is what I told you here P dot happens to be like that. So, what is the summary part of it again here, the model is given like this, the continuous time model measurement is like this discrete time, initialize the state vector as well as the covariance matrix, we will compute the gain which is **actually** discrete time manner k is like this (Refer Slide Time: 43:05).

Well then once you once you compute the gain, you will be able to correct the state vector, starting from the predicted value you can get the updated value, using this innovation term. Then we need to get ready with the next time step, next time step you can propagate that way, the state equation can be propagated using this this part of a system dynamic; not including noise. And this covariance matrix can also be propagated actually again this this symmetric form is preferable.

So, propagation sense we will make use of this propagation as I told and we will also make use of this propagation term, and I mean this continuous time covariance matrix to propagate actually alright. So, this is what I mean is this this covariance matrix can can also be updated there, let me (()) not only updating this state equation state information here with the measurement, we will also update the covariance matrix here. Then we will propagate the covariance matrix using the continuous time expression that is available, so this is update stage (Refer Slide Time: 43:52).

Both the both the state vector as well as covariance matrix will be updated, then they will be propagated by one more time state actually, remember the way it is mechanized it does not really require uniform delta t that means, the propagation time state and updated time state need not be same actually. You keep on propagating as long as the sensor information is not available, the moment sensor information is available, you update the information that you have actually, so that is a where you need to have mechanization actually.

And so this what I already told, and then this is what you told is like P dot expression is a continuous time (()) equation, if you see this there is no more Riccati equation basically, it is in a discrete, I mean continuous discrete framework, it terms out to be nothing but, a (()) equations sort of thing. Now, finally, with this information we will be able to touch up on this this this external command filter, which is very popular in industry, and most of the time people use that, that extended Kalman filter.

(Refer Slide Time: 45:37)

Facts to Remember

Nonlinear estimation problems are considerably more difficult than the linear problem in general. (EKF is just an idea...not a cure for everything !)

The problem with nonlinear systems is that a Gaussian input does not necessarily produce a Gaussian output (unlike linear case)

The EKF even though not truly 'optimum', has been successfully applied in many nonlinear systems over the decades

The fundamental assumption in EKF design is that the true state $X(t)$ is sufficiently close to the estimated state at all time, and hence the error dynamics can be represented fairly accurately by the linearized system about $\hat{X}(t)$

MPTEL
ADVANCED CONTROL SYSTEM DESIGN
Dr. Radhakant Padhi, AE Dept., IISc-Bangalore

So, first you remember, first is non-linear estimation problems are **are** considerably more difficult, than the linear problems in general, and EKF turn out to be an idea, but not a cure for everything that means, that you just cannot have, because I know EKF, **I will** I will be able to solve everything. What surprisingly turns out that EKF **actually**, works for a variety of problems, **actually** large number of problems EKF does work, but some cases it may not work also because, EKF is not a very rigid precise, theory **it is** it is an extensive idea really.

So, what the problem, problem is like if the non-linear system, even if you take Gaussian input, it really does not translate, it does not retain in the Gaussian nature **actually**, if it is a linear system the nature of the Gaussian nature remains in that what the non-linear case does not **actually**. What is the assumption, fundamental assumption, what you are assuming in **in** external Kalman filter, is that the true state is sufficiently close to the estimated state **actually** already; an implementation, it may not be **actually** initially you will not be able to guess a very close state information and all that; that is one of the most one of the difficulties of course. Because, universal stability like linear system theory is not available, guess will play a role and if your guess is too far away you will have a problem **actually**.

But, it turns out that you can have a fairly large amount of error in the initial guess, you can go through a large amount of transient, what it will ultimately settles out nicely **actually**.

Anyway, coming back what it assumes that true state is sufficiently, close to the estimated state, and hence we can **actually** linearize the non-linear system, about the estimated set and then use the linear theory that we have used discussed before **actually**, that is what the idea. So, let us talk about the most popular form continuous discrete EKF and that is most natural form also system dynamics is continuous, but measurement is discrete again.

(Refer Slide Time: 47:37)

Continuous-Discrete EKF

Motivation: System dynamics is a continuous-time, whereas measurements are available only at discrete interval of time.

Strategy:

Without the availability of measurement, propagate the state and co-variance dynamics from $\hat{X}_k^+ \rightarrow \hat{X}_{k+1}^-$ and $P_k^+ \rightarrow P_{k+1}^-$ respectively, using the "nonlinear system dynamics" and linear co-variance dynamics.

As soon as the measurement is available, update $\hat{X}_{k+1}^- \rightarrow \hat{X}_k^+$ and $P_{k+1}^- \rightarrow P_k^+$ respectively.

NPTEL
ADVANCED CONTROL SYSTEM DESIGN
Dr. Radhakant Padhu, AE Dept., IISc-Bangalore

So, what you do here, so similar idea, like we will be able to, like **with** without the availability of measurement, we will be able to propagate the state information as well as the covariance information for to the next time state. And as long as the system dynamics is available will be able to correct it **actually** **sorry**, as long as the measurement information is available, we can update this **this** predicted values to corrected values really, so **that is** that is the way it will really precede **actually**. Now, so what is the summary of this the entire derivation, we will not go through probably, but the summary part is something like this, we have the system dynamics like this, where f of X is $T U$ this is the non-linear system dynamics remember that. But, we still assume that the noise part is additive and noise part appears linearly rather, and this output is **is** again a non-linear expression plus V_k . Remember, the system dynamics is continuous, but like measurement is **actually** discrete probably you can put here k .

So, again **the** with mechanize, we need some initial condition and then that initial condition we have to guess, and so except **k** **sorry**, except minus T_0 is X_0 , that is a guess, and P_0 minus expected value of that, and that also value of this matrix needs to be guessed, most of the time these values are guessed as diagonal matrices **anyway**. So, **this is** this is what is required, then we will have again computation like fairly similar to what we discussed in the continuous discrete form of regular Kalman filter for linear systems, we will do that, but remember these are matrices now.

So, matrices are this C_k minus what you are using here is to be estimated this way **actually** that means, you take linearization of this output equation. So, C_k minus is linearized form of this equation actually, so that is what we will go here. And similarly, we will need, **I mean** once you compute this Kalman gain, you will be able to use that for the update equations, and this expressions and all we have derived before. So, that is exactly same thing that we will be using, and then the after we are done with this we need to have propagation thing, and propagation happens to be like that.

So, we have a state equation which can be propagated without noise part of course, and then it is a covariance matrix, **I mean** differential equation which will need to integrate each other. So, that using that will be able to propagate, and here this a matrix is again a Jacobean matrix this is derived $\frac{\partial f}{\partial X}$, and which is evaluated about the current estimate \hat{X}_T . So, A_T and C_T will be required here, C_k minus and all that, and these are **actually** a nothing but, the linearization of the system dynamics and output equation what you have, about the current estimate what you have **actually**.

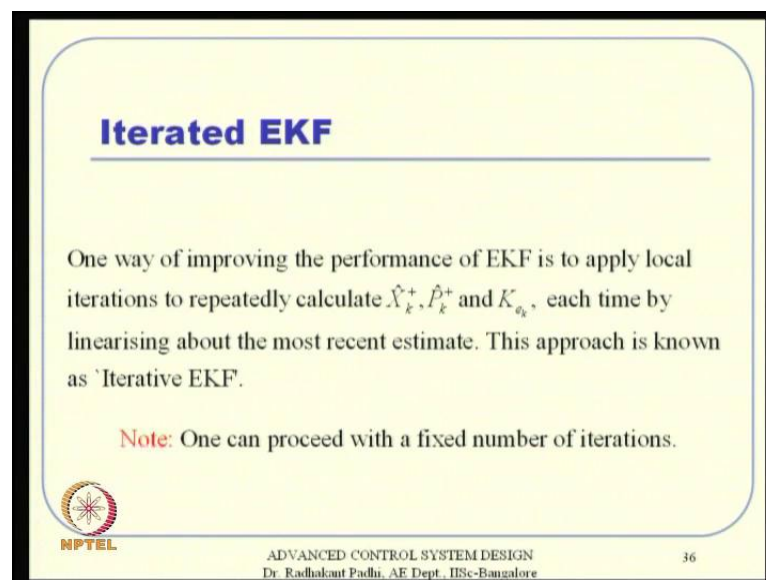

So, once you are ready with these matrices, you can keep that as a that point of time that is my time varying system dynamics matrix that I have, and for that I already know how to deal with **actually**, because continuous discrete Kalman filter for linear system is available to be, so this is how **how** you operate **actually**. So, every point of time you generate A and C matrices about it something like a time varying linear matrix sort of thing, and then using your like regular linear system **Kalman theory** Kalman filter theory you will be able to compute the necessity matrices and all, so **so** again this operates based on this prediction correction, prediction correction like that **actually**. So, we also have an idea of this

something called iterated EKF, that is the fundamental EKF anyway, but you will see that, the plenty of ideas of various extensions. And then various arts and all like how do you implement, what do you do depends on your system dynamics, depends on your experience, depends on your insight to the problem, many **many many** things will happen around that **actually**.

So, one of that happens to be this iterated EKF however, that tell once I update this equations here, let me again go back and tell **can I** can I update one more time, can I update one more time like that **(())**; you get the system matrix if this is talking about some sort of a linearization here, and linearization is about my predicted value. So, let me do the linearization again the **I mean** with respect to the corrected value also, and operate the filtering equation one more time **actually**. So, that one you can keep on doing that, because you keep on updating your state in covariance matrix **anyway**.

So, I will just update it and go back and tell I will reevaluate this **this** $C_k X_k$ minus matrix about this except k plus norm and then I will use that one **actually** norm, so you keep on updating several times. So, before you proceed, **I mean** talk somewhere preferably after some conversions happen, and then you start your propagation equations **actually**, you start using a propagation equation.

(Refer Slide Time: 52:43)

Iterated EKF

One way of improving the performance of EKF is to apply local iterations to repeatedly calculate \hat{X}_k^+ , \hat{P}_k^+ and K_{e_k} , each time by linearising about the most recent estimate. This approach is known as 'Iterative EKF'.

Note: One can proceed with a fixed number of iterations.

 NPTEL

ADVANCED CONTROL SYSTEM DESIGN
Dr. Radhakant Padhi, AE Dept., IISc-Bangalore

36

This is the whole idea of iterated EKF and one can proceed with a fixed number of iterations, does not have to really wait for convergence and all, we can simply use some (∞) and all that, before you proceed further; this is remember, these are all like **like** real time computation is should be addressed also, because without that this (∞) also we will see. So, we can use it based on fixed number of iteration then go to the next step, go to the next step like that way **actually alright**.

(Refer Slide Time: 53:11)

Recommendations/Issues in EKF

- > **Design parameter selection:**
 - o Fix R based on the sensor characteristics
 - o Select P_0 to be "sufficiently high"
 - o Tune Q until obtaining satisfactory results
- > **The filter should run sufficiently ahead of time prior to its usage, so that the error stabilizes before its actual usage (else, initial error can be very large and the associated control can destabilize the closed loop system)**
- > **Keep the measurement equation linear wherever possible**
- > **Care should be taken to avoid numerical ill-conditioning wherever possible. If necessary, use scaling techniques available to address this issue (see Crassidis and Jerrells)**

NPTEL
 ADVANCED CONTROL SYSTEM DESIGN
 Dr. Radhakant Padhi, AE Dept., IISc-Bangalore

So, there are various recommendations and issues in EKF, so **before talking I mean** before stopping this lecture, and winding up this course let me talk, several small **small** recommendation that are given for successful implementation of EKF, and again I will talk in a very generic sense basically. So, first thing is the design choice and all that, so design parameters lot of times you will see in a literature, that they are the recommendations that will perform.

So, remember there is the tuning sense, what we really need is a initial condition guess for the state vector, and other than that we need values for this matrices R P Q and R **right**, P Q and **I mean** what they call P Q and R sort of thing, but you can think of that. So, what they tell is like first thing is you fix your R matrix, because R is nothing but, sensor providence matrix. So, depending on what type of sensors that you have, that will **that will**

be fixed from there, because you study the nature of your sensors and then find out the covariance matrix from that, and that is the reality, so do not try to that **actually**.

So, keep your R matrix fixed based on the sensors that you are using, then you select a P naught with sufficiently high, that the lot of times you will see that P naught value is recommended to be very high, and that **actually** helps in some sort of a stability behaviour **actually**. That means, even though your initial condition guess is large enough, **(())** if your P naught is sufficiently high in terms of the filter thus converge, after some initial transient of course.

Now, once you fix R from the sensors and fix P naught sufficiently high, the only flexibility that you are left out with Q basically. So, you have to tune Q until **I mean until** you obtain satisfactory result basically, so that is the standard recommendation **that** that is there in **in** much literature **actually**. So, you can be say, if you see that, as I told this EKF and all, you it will go through initial large transient **actually**. So, initially it will got through large transient, and then ultimately it will try to settle and after that the error will be small **actually**.

So, obviously, do not want to use this transients values, which are error nears any way, so **what you** what you have to do is probably **you should** you should run the filter sufficiently ahead of time prior to its usage. So, that the error stabilizes before it is usage **actually**. So, especially when you want to close in that means that may you want to operate the estimation into the control design and think like that. So, recommendation is used, you use the filter for a, **I mean** you start operating your filter in the background for some time, and then after sometime only you close the loop for the controller **actually**. So, that means, by that time the error is stabilized error is small, and then it will operate as if it will like to estimate the state and all that **(())**. So, anyway we will see that there is some sort of an initial time log given to the filter to stabilize, before it is **actually** usage **actually**.

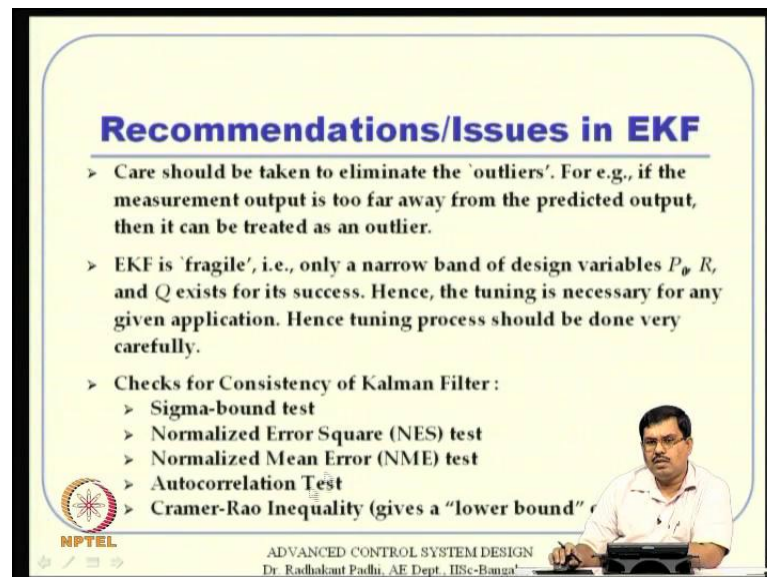

There is another recommendation, I have seen many times, that we lot of people are in favor of the idea of that measurement equation is to be linear as much as possible, for example, **I mean** the theory tells that I can linearize the measurement equation as well and obtain a C matrix. But, in general what lot of practicing engineers **actually** work, but observe that **if you** if you keep the measurement equation linear wherever possible, then it leads to better

stability for produce of the filter, that is just some sort of an experienced recommendation sort of thing, there is no **no** theory reasoning to make it off **actually**.

So, one example is for example, if you are talking about something like a **(O)** gradient problem **(O)** rather just information in polar coordinate, then the system dynamic associated with that is you should also use in polar coordinate; estimate the states in polar coordinate, and then transform it to Cartesian coordinate if you need **actually**. But, if you start with a Cartesian coordinate itself, and use polar coordinate information as of sensor output, then it will the measurement equation becomes non-linear, once you start linearizing it you are truncating the information. So, these are some of the issues that you want to avoid **actually**, so that is another recommendation.

(O) should be taken to avoid numerically conditioning **actually**, that you can see some of this accommodation in this crass dies, and book these are all of my discussion from this book, and you can see that one of the recommendation, as I told is you need to use this expression for **for** this P_k plus instead of that simplified expression. If you use this **this** will have better numerical property, even though both these expressions are identical, mathematical, so that is another care, that you need to take **actually**.

(Refer Slide Time: 57:59)

Recommendations/Issues in EKF

- > Care should be taken to eliminate the 'outliers'. For e.g., if the measurement output is too far away from the predicted output, then it can be treated as an outlier.
- > EKF is 'fragile', i.e., only a narrow band of design variables P_0 , R , and Q exists for its success. Hence, the tuning is necessary for any given application. Hence tuning process should be done very carefully.
- > Checks for Consistency of Kalman Filter :
 - > Sigma-bound test
 - > Normalized Error Square (NES) test
 - > Normalized Mean Error (NME) test
 - > Autocorrelation Test
 - > Cramer-Rao Inequality (gives a "lower bound")

NPTEL
ADVANCED CONTROL SYSTEM DESIGN
Dr. Radhakant Padhi, AE Dept., IISc-Bangalore

One more big recommendation is we need to eliminate out layers **actually**, so sometimes this **this** sensor information are not really good, and we and this EKF, **actually** gives us a platform, because we have a predicted state, we have a measurement equation **actually**. Which is like Y and \hat{Y} sort of thing, and if the innovation term is really very big, then I do not want to come for that, if it is reasonably small and all I will assume the sensor is correct I will update.

If it is too high too big, then probably momentarily I need to ignore that, I will consider that some sort of an out layer and just taken out that **actually**. Also remember that, EKF in general is fragile **that** that means, the only a narrow brand of design variables will be very good for **for** successful operation; if you do not lose your presence what I mean, keep on tuning this and ultimately, you will see that EKF **actually** works wonderfully for a for a number of problem.

But, you need to have presence for making it operation or **(O)** **actually** and there are ultimately, there are consistency checks of the Kalman filter, there are various checks **actually**, one is sigma bound test, normalized error square test, normalized mean square test, for autocorrelation test and all that, **(O)** inequality test and all that. So, there are various test available, and at least where few of them needs to be done to have confidence in your estimation and all that, that is a really recommended and they were need to do that **actually** **(O)**.

There are limitations where linearization is not good general convergence guarantee convergence guarantee is not there and many issues, because of that there are other ideas available beyond EKF **actually**. And I will not discuss too many on that, if you are interested you can see EKF you can see particular filter, you can say **actually** kind of filtering lot and lot, lot things etcetera.

So, with that probably I will stop here but, then the reference books are available the first book is my most favorite book and that is what I have taken from; second one is also good, and you can see some other books available or very good application, book there are theory books like that **actually**, so with that I will stop here thanks a lot.
