Lecture No. # 20

Dynamic Programming

All right everybody, we will start with our lecture series on lecture number twenty on this optimal control, guidance and estimation course.

(Refer Slide Time: 00:20)

So far, you have seen this optimal control formulation from **calculus** of variations point of view. But, for here we will see a very different perspective. So, let us get started.

(Refer Slide Time: 00:41)

The first thing is motivation and fundamental philosophy, what is there in that. Then, we will continue with this Hamilton-Jacobi-Bellman theory. This is the backbone of this dynamic programming. Then, we will obviously give some examples and list out certain important facts. And then, I will also give some references for everybody to follow.

(Refer Slide Time: 01:07)

This motivation and fundamental philosophy is like this.

(Refer Slide Time: 01:16)

Hamilton-Jacobi-Bellman (HJB) Theory

Motivation / Objective
To obtain a “state feedback” optimal control solution

Fundamental Theorem
Any part of an optimal trajectory is an optimal trajectory!

The diagram illustrates the fundamental theorem. It shows a solid yellow curve labeled 'Optimal path' starting at point A, passing through point C, and ending at point B. A dashed line labeled 'Non-optimal path' also starts at point A and ends at point B, but it is lower than the optimal path. A small inset image of a man is visible in the bottom right corner of the slide. The NPTEL logo is in the bottom left, and the text 'OPTIMAL CONTROL, GUIDANCE AND' is at the bottom center.

The first motivation is to obtain a state feedback optimal control solution. So far, what you have seen in calculus of variation and the necessary conditions and then two point boundary value problem and things like that. If you remember, it is ultimately to get a trajectory from a given initial condition. So, what you are interested in here is to obtain some sort of a tunnel of trajectories. In other words, given any initial condition, which we will be able to find a solution for the control – now, what does that mean? That means there is something like a state feedback optimal control. Given a state, you want to find out what is the control. And, remember, this control need not be a linear function; it can be any function of state. However, given the state, we will be able to compute the control; that is more important.

What is the fundamental theorem associated with that? It relies on this very intuitive piece of argument that any part of an optimal trajectory is an optimal trajectory; feels obvious, but it is little bit involved to kind of see that. This we are... Intuitively, we will show that here. Let us see, we have found out something like an optimal path from point A to point B via point C. So, this is somehow we have already found out the optimal path. Now, what this theorem tells us is any part, even if you take a small piece of this trajectory, is certainly going to be optimal by itself. And remember, that is a different problem altogether. Problem starts from A and stopping at B, is different from problem starting at A and stopping at C; think like that. So, what this theorem tells us again is if I take any slice of this trajectory, it is going to be optimal by itself.

How does the argument goes? Let us see that we find some other path from point A to C; and, from C to B, we will follow the same; already found an optimal path. Then, what does it tell? Now, let us say that this is optimal (Refer Slide Time: 03:11). If this optimal, then this cost function associated from point A to C, is lesser than this path. So, in principle, you could have taken this path from A to C, this dotted line; and, C to B you could have followed. And then, this path from this dotted line A to C and then C to B – that would have been our optimal path. But, this is not the optimal path, **because** we started with this A to C via this top line; and, that we claim that is the optimal path that we have already found. And hence, this cannot be the optimal path from point A to C. So, that is the very fundamental intuitive argument sort of thing, which tells us that any part of an optimal trajectory is an optimal trajectory itself. So, let us see how do we use this and to derive this HJB equation.

(Refer Slide Time: 03:59)

This is famously called Hamilton-Jacobi equation, but later on this name Bellman was also added to it, because of its own country using. So, now, it is famously called as HJB equation or Hamilton-Jacobi-Bellman equation.

(Refer Slide Time: 04:14)

Optimal Control Problem

Minimize $J = \int_{t_0}^{t_f} L(t, X, U) dt$

Subject to $\dot{X} = f(t, X, U), \quad X(0) = X_0 : \text{Fixed}$
 $t_f : \text{Fixed} \quad X_f : \text{Free}$

where the input $U \in \Omega : \text{an admissible set}$
(which may be finite or infinite)

OPTIMAL CONTROL, GUIDANCE AND ESTIMATION 6

The problem is like this. Again, we go back to this fundamental problem. We want to minimize this cost function subject to this state equation. We have an initial condition and we have final time fixed and we also consider X_f being free. Very standard thing, now, what we have been considering so far; the only difference here is outside the cross function, there is no term. That means there is no terminal penalty **for say** here. And, this is purposefully done, while introduced this terminal penalty slightly later. It does not have the derivation to begin with. And later, we will try to introduce that also.

And also, remember the control here is bounded. That means this Ω is an admissible set (Refer Slide Time: 05:03); and, any solution that lies outside this Ω , we are not interested in. However, this Ω can be infinite as well; that means if you really want to formulate a problem, where the control variable is unbounded, then this is also feasible. But, if it is bounded, for most of the practical application we are interested in bounded set only, then also, this formulation is capable of handling that.

(Refer Slide Time: 05:35)

Hamilton-Jacobi-Bellman (HJB) Equation

Let us assume that we have obtained the optimal control U^* (in the state feedback form), and hence, the corresponding optimal trajectory X^* . Then the cost function is a function of the initial state $X_0^* = X_0$ and initial time t_0 (since t_f is fixed).

Let us denote the optimized cost function as

$$V(t_0, X_0) = \int_{t_0}^{t_f} L(t, X^*, U^*) dt$$

 OPTIMAL CONTROL, GUIDANCE AND

A man in a white shirt and glasses is speaking in the bottom right corner of the slide.

Let us see how things proceed. Now, let us assume that we have already obtained an optimal control solution U^* that is already available to us in the state feedback form. And hence, the corresponding optimal trajectory X^* is also available. Just for a second we assume that this control has been found out, which is optimal control already; and associated with that, this X^* is also available. Then, the cost function is a function of the initial state only and obviously initial time as well. Remember, this cost function – if you see that a little bit, this cost function is here (Refer Slide Time: 06:15). We have found an optimal trajectory and an optimal control associated with that. And, remember, t_f is fixed. So, there is no variation on that. So, what remains is initial condition and initial time. So, this needs to be optimized.

And, let us denote the optimized cost function as something like this (Refer Slide Time: 06:35). Now, remember, if I evaluate this cost function now, it becomes a function of only t and x here (Refer Slide Time: 06:42). So, this cost function what I am getting here, I can denote it something like V , is a function of t and x . Why we are specifically interested in this? If somebody wants to know, ultimately, this x is nothing but the current state and t is nothing but the starting time; wherever I am, that is the t and whatever x I am having, that is x . So, I want to interpret this entire problem as something like initial time and initial state. So, this V is defined as something like this. Everything else is evaluated such that it remains as a function of t and x .

(Refer Slide Time: 07:22)

Hamilton–Jacobi–Bellman (HJB) Equation...contd.

Let us consider a small time step Δt between t_0 and t_f .

Then $V(t_0, X_0)$ can be written as

$$V(t_0, X_0) = \int_{t_0}^{t_0 + \Delta t} L(t, X^*, U^*) dt + \int_{t_0 + \Delta t}^{t_f} L(t, X^*, U^*) dt$$

Define:

$$J_0(X^*, U^*) \triangleq \int_{t_0}^{t_0 + \Delta t} L(t, X^*, U^*) dt$$

OPTIMAL CONTROL, GUIDANCE AND ESTIMATION

8

Now, let us consider a small time step Δt between t_0 and t_f . So, what we are telling is, there is a t_0 there; it starts with something like this; there is a t_0 and there is a t_f ; the trajectory is there, t_0 to t_f . But, what I am interested is t_0 to some Δt . And then, this one is rest of the time. This is what I am interested in. Then, what I am interested, what needs to be done here is this is V of t_0 , X_0 , which is nothing but an integral. Remember, V of t_0 is something like this (Refer Slide Time: 08:11) – t_0 to t_f . So, what I have done is, this entire segment of t_0 to t_f , I have divided in two parts: one is t_0 to $t_0 + \Delta t$ and the other one is $t_0 + \Delta t$ to t_f . So, obviously, this integration formula that we know can be split into something like this (Refer Slide Time: 08:27). First is t_0 to $t_0 + \Delta t$; and, the second part is $t_0 + \Delta t$ to t_f .

Next, we define something like this (Refer Slide Time: 08:37). So, this is a definition symbol, because of this power point version, there is some message here. So, essentially, you can define it something like this. This J_0 – I define it as something like this (Refer Slide Time: 08:55). So, what happens here is, I want to analyze this particular thing little more carefully; and, rest of the things is the optimal cost anyway. Remember, this is the optimal cost already (Refer Slide Time: 09:10); this is (Refer Slide Time: 09:15) optimized cost. So, if I have a path from $t_0 + \Delta t$ to t_f , that becomes an optimized cost from that point of time; that will also use **that**. Now, this particular time, I mean this (Refer Slide Time: 09:28) t_0 to $t_0 + \Delta t$ is the

immediate effect of the control. And hence, I want to give you a little bit more emphasis for that.

(Refer Slide Time: 09:36)

Hamilton–Jacobi–Bellman (HJB) Equation...contd.

By fundamental theorem,

$$\int_{t_0 + \Delta t}^{t_f} L(t, X^*, U^*) dt = V((t_0 + \Delta t), X_0(t_0 + \Delta t))$$

This leads to:

$$V(t_0, X_0) = J_0(X^*, U^*) + V((t_0 + \Delta t), X_0(t_0 + \Delta t))$$

OPTIMAL CONTROL, GUIDANCE AND ESTIMATION
Dr. S. S. Raju, IIT Madras

9

Then, what happens here? Then by using this fundamental theorem as I told, that means, any part of the optimal trajectory is also optimal. What you can claim first is $t_0 + \Delta t$ to t_f , that part of the cost function is same as this one. That is also an optimal path. So, this leads to this kind of identity that $V(t_0 + \Delta t, X_0(t_0 + \Delta t))$ is nothing but $J_0(X^*, U^*)$. This is coming from (Refer Slide Time: 10:05) the first part of it; and, the second part is coming from this side here. So, some people call this as cost to go and something some people call it a utility function and things like that. So, this is also possible to define. In the next class, we will see in approximate dynamic programming. Those are the things terminologies used there. Just to repeat, this is the utility function and this is the cost to go from $t_0 + \Delta t$.

(Refer Slide Time: 10:43)

Hamilton–Jacobi–Bellman (HJB) Equation...contd.

Combining these results and observing that $\dot{X}_0 = f(t_0, X_0, U_0)$, we get

$$V(t_0, X_0) = \Delta t L[t_0 + \alpha \Delta t, X^*(t_0 + \alpha \Delta t), U^*(t_0 + \alpha \Delta t)] \\ + V(t_0, X_0) + \left[\frac{\partial V(t_0, X_0)}{\partial t_0} \right] \Delta t + \left[\frac{\partial V(t_0, X_0)}{\partial X_0} \right]^T f(t_0, X_0, U_0) \Delta t + HOT$$

Canceling the term $V(t_0, X_0)$ from both sides and taking the limit $\Delta t \rightarrow 0$, it leads to

$$\left[\frac{\partial V(t_0, X_0)}{\partial t_0} \right] + L[t_0, X^*(t_0), U^*(t_0)] + \left[\frac{\partial V(t_0, X_0)}{\partial X_0} \right]^T f(t_0, X_0, U_0) = 0$$

OPTIMAL CONTROL, GUIDANCE AND ESTIMATION 11

Now, what? Let us try to analyze this little more.

(Refer Slide Time: 10:44)

Hamilton–Jacobi–Bellman (HJB) Equation...contd.

Assuming L to be smooth over the interval t_0 to $(t_0 + \Delta t)$, Δt to be "sufficiently small", and taking $\alpha \in (0, 1)$,

$$J_0(X^*, U^*) = \Delta t L[t_0 + \alpha \Delta t, X^*(t_0 + \alpha \Delta t), U^*(t_0 + \alpha \Delta t)]$$

Using Taylor's theorem

$$V(t_0 + \Delta t, X_0(t_0 + \Delta t)) = V(t_0, X_0) + \left[\frac{\partial V(t_0, X_0)}{\partial t_0} \right] \Delta t \\ + \left[\frac{\partial V(t_0, X_0)}{\partial X_0} \right]^T \underbrace{\dot{X}_0 \Delta t}_{\Delta X_0} + HOT$$

OPTIMAL CONTROL, GUIDANCE AND ESTIMATION 10

Now, first thing is this portion. Now, this portion is something like this (Refer Slide Time: 10:52). This portion can be written as... This is nothing but an integral (C) This j naught of X star, U star is nothing but that integral there – this integral (Refer Slide Time: 11:07). So, this integral can be approximated or using this calculus ideas, what you can do is, we can write it this way. We assume that this L to be smooth over the

interval; obviously, L is part of a cost function what we select. So, obviously, it has to be smooth.

And also, Δt needs to be sufficiently small. And then, there is a theorem in calculus, which tells us that if I select an α properly between 0 and 1, then I can exactly write this equation that way. It is almost like trapezoidal rule, but it is something like... Let me pictorially try to put it for the benefit of you over there. What you telling here is, there is a function here; I want to integrate this; what it tells is, there is some value, about which if I take the area of this particular rectangle, then this is same as area under the curve. But, it is not of a three volume thing; there exist an α between 0 and 1, so that this is identically equal.

Now, what about the next one? If you remember, there are two parts (Refer Slide Time: 12:28). One is this part also. That part – you can take this Taylor's theorem now (Refer Slide Time: 12:39). What does this Taylor's theorem tells us? That if there is an increment of a function something like this, I can always use the Taylor's series and write it this way. First is V of t naught, X naught; second term is for this first order term with respect to Δt ; and, the first order term with respect to Δx . For this, Δx naught, I can always write it in this way (Refer Slide Time: 13:00); X naught dot times Δt also. So, this is what using Taylor's theorem and taking up to the first order terms and keeping the higher order terms this way.

(Refer Slide Time: 13:15)

Hamilton–Jacobi–Bellman (HJB) Equation...contd.

Combining these results and observing that $\dot{X}_0 = f(t_0, X_0, U_0)$, we get

$$V(t_0, X_0) = \Delta t \left[L(t_0 + \alpha \Delta t, X^*(t_0 + \alpha \Delta t), U^*(t_0 + \alpha \Delta t)) \right. \\ \left. + V(t_0, X_0) + \left[\frac{\partial V(t_0, X_0)}{\partial t_0} \right] \Delta t + \left[\frac{\partial V(t_0, X_0)}{\partial X_0} \right]^T f(t_0, X_0, U_0) \Delta t + HOT \right]$$

Canceling the term $V(t_0, X_0)$ from both sides and taking the limit $\Delta t \rightarrow 0$, it leads to

$$\left[\frac{\partial V(t_0, X_0)}{\partial t_0} \right] + L(t_0, X^*(t_0), U^*(t_0)) + \left[\frac{\partial V(t_0, X_0)}{\partial X_0} \right]^T f(t_0, X_0, U_0) = 0$$

OPTIMAL CONTROL, GUIDANCE AND ESTIMATION
Dr. G. B. ...

11

Next, what happens? Now, we combine both the things; then, what happens is V of t naught, x naught; this is the first part, what we get from that calculus area equality; and, this is what the second part, what we got from the Taylor's series expansion. Now, remember, this part – this (Refer Slide Time: 13:34) X naught dot is nothing but f of t naught, X naught, U naught; that is from the system dynamics. So, now, I get some form of something like this. So, what can I do now? You can very clearly see that there is a V naught t naught X here and there is a V naught t naught X here. So, I can actually get rid of these two. If I do that, then what I do is I take Δt tends to 0. So, I can divide everywhere by Δt and things like that.

Remember, the higher order terms will have Δt square and things like that; so, Δt square, Δt cube and all higher order terms. So, what happens here, even if I divide it by Δt and then Δt tends 0, then all these terms will go to 0. So, what remains here? First term is this term (Refer Slide Time: 14:24). Remember, first order Δt 's are gone. So, this is the first term; coming from here is the first term. And, coming from here, this term is here; and, coming from here, remember, Δt 's are all tends to 0; that means all Δt 's are gone here. What is remaining is this one. So, this now you can recognize that as I told you sometime back that what you are interested is solution from current time and current state.

(Refer Slide Time: 14:59)

Hamilton–Jacobi–Bellman (HJB) Equation...contd.

Next, define $\lambda \triangleq \frac{\partial V(t, X)}{\partial X}$

For convenience (since we are interested to obtain the solution for any initial condition), we drop the subscript "0". Then we can write

$$\left[\frac{\partial V(t, X)}{\partial t} \right] + L(t, X, U) + \lambda^T f(t, X, U) = 0$$

HJB

OPTIMAL CONTROL, GUIDANCE AND ESTIMATION

12

So, all these, what you see here, these arguments can be dropped; this t naught, X naught and all that, you can interrupt with that as current time and current state. So, these arguments I can drop out and write these expressions little bit later. But, before that, I can also define... Again, this is the definition symbol; I can define δV by δX as nothing but λ . And, in fact, just to comment, from this definition, δV by δX happens to be the same λ coming from calculus of variation (()) So, this gives us some different interpretations for this co-state variable λ , which tells us, λ is nothing but the sensitivity vector of the optimized cost function with respect to state.

Anyway, coming back to that, we just define λ like that. So, what you see here (Refer Slide Time: 15:52) is nothing but λ^T . The only difference is this V remember is not that cost function; it is the optimized cost function. After you find the control solution, after you put it by and evaluate the cost function, that is the optimized value of the cost function. Anyways, using this definition of λ (Refer Slide Time: 16:14) and dropping the arguments t naught, X naught to t and X , what you get here is this one (Refer Slide Time: 16:19). Then, this equation is famously called as HJB equation (Hamilton-Jacobi-Bellman equation). But, also remember, what is L plus $\lambda^T f$. If you remember this part, this L plus $\lambda^T f$ – if you remember, this is nothing but Hamiltonian. But, this is not any Hamiltonian, because remember, this λ involves V and all that; V is an optimal curve. So, this is optimized Hamiltonian.

(Refer Slide Time: 17:01)

Summary of HJB Equation

- Define optimized cost function V as:
- Then $V(t)$ must satisfy:

HJB equation

$$\frac{\partial V}{\partial t} + H_{opt} = 0$$

where,

$$H_{opt} = \min_{U \in \Omega} (H) = \min_{U \in \Omega} (L + \lambda^T \dot{f})$$

and $\lambda = \frac{\partial V(t, X)}{\partial X}$

$$V(t, X) = \int_t^{t_f} L(t, X, U) dt$$

OPTIMAL CONTROL, GUIDANCE AND ESTIMATION

14

So, this is what is defined.

(Refer Slide Time: 17:04)

Hamilton-Jacobi-Bellman (HJB) Equation...contd.

We define H_{opt} □ Hamiltonian for the optimum control
With this, finally we get

$$\frac{\partial V}{\partial t} + H_{opt} = 0$$

where $H_{opt} = \min_{U \in \Omega} (H) = \min_{U \in \Omega} (L + \lambda^T f)$

This is called Hamilton Jacobi-Bellman (HJB) equation

 OPTIMAL CONTROL, GUIDANCE AND ESTIMATION 13

We define this H_{opt} to be Hamiltonian for the optimal control. And, with this definition, this $\frac{\partial V}{\partial t} + H_{opt}$ is equal to 0; that is that what you can write. So, that is what we can write here. I can tell that $\frac{\partial V}{\partial t} + H_{opt}$ is equal to 0; that is very famously called HJB equations, where this H_{opt} is minimum Hamiltonian over this constraint set Ω . So, this has to be found out first. As I told, this optimizes Hamiltonian is to be found out. And then, you put it back here and whatever equation you get is called HJB equations. We will see examples and how to do that.

What is the summary of HJB (Refer Slide Time: 17:59) equation? First, you define this cost function; V of t, X is equal to that way. And then, this V must satisfy this equation, $\frac{\partial V}{\partial t} + H_{opt}$ equal to 0. It is very easy to remember way the. All that is to remember very quickly, $\frac{\partial V}{\partial t} + H_{opt}$; that is equal to 0. But, also remember this H_{opt} is optimized Hamiltonian; that means you have to put the definition of Hamiltonian first, L plus $\lambda^T f$, where λ is defined to be $\frac{\partial V}{\partial X}$. And then, you can substitute the expression $(())$ here and solve it further to get control in all that. How do you do that? I will give an example to demonstrate that. Remember, L contains a control and f contains a control. So, those control variables need to be solved as a function of λ and X . But, λ – remember, is also a function of $X, \frac{\partial V}{\partial X}$ sort of things. It will all come in some sort of a state feedback form.

(Refer Slide Time: 19:06)

**Dynamic Programming:
Some Relevant Results**

1. If Ω is infinite, H_{opt} can be computed by computing U
(as a function of X & λ)
from $\frac{\partial H}{\partial U} = 0$
2. Let us consider the case when t_f is fixed and X_f is free
(a) if $J = \int_{t_0}^{t_f} L(t, X, U) dt$
then $V(t_f, X_f) = \int_{t_f}^{t_f} L(t, X, U) dt = 0$

 OPTIMAL CONTROL, GUIDANCE AND ESTIMATION 15

If I move further, there are certain relevant results. Let us first see that. And, the first result tells us that if omega is infinite, that means we talk about something like an unconstrained control problem. Control variable is not confined to a particular finite set sort of thing. Then, this H_{opt} can be computed by computing this equation, $\frac{\partial H}{\partial U} = 0$. That is what we have seen from the other side of the story, calculus of variations. So, if you put this equation, $\frac{\partial H}{\partial U} = 0$ and solve for whatever control expression as a function of state and co-state, X and λ , then that is the way to proceed.

You put this equation, $\frac{\partial H}{\partial U} = 0$; get a control as a function of state and λ ; and then, wherever control appears here (Refer Slide Time: 20:01) in this equation, substitute it there and try to solve for... Some people try to solve for V directly, because this equation is interpreted as a function of V finally. So, you solve it for V . And, once you solve for V , then λ is available. And, once λ is available, remember, all these are available as mathematical expressions. So, once λ is available, you can get the control back from this equation (Refer Slide Time: 20:25).

Now, what is the second comment? Second result tells us that when t_f is fixed and X_f is free, if J is like (Refer Slide Time: 20:38) this, then the final boundary conditions tells us that if you put V of t and X ; instead of t_0 , you put t_f . So, V of t_{naught} , X_{naught} – if

you remember, that is the definition starting from t_f . Now, what I put is V of t_f, X_f ; first, the boundary conditions **sort of thing**. Then, this t_f , and I have to put t_f ; and hence, it does not matter; t_f to t_f , **an** integration of any integrand integrating over the same interval happens to be 0. So, what you are getting here is if t_f is fixed and if X_f is free, that is what we started with, then this is the boundary condition that we need to use.

(Refer Slide Time: 21:21)

**Dynamic Programming:
Some Relevant Results**

(b) if $J = \phi(t_f, X_f) + \int_{t_0}^{t_f} L(t, X, U) dt$

then $V(t_f, X_f) = \phi(t_f, X_f) + \int_{t_f}^{t_f} L(t, X, U) dt = \phi(t_f, X_f)$

3. If $t_f \rightarrow \infty$, $\frac{\partial V}{\partial t} = 0$

NPTEL OPTIMAL CONTROL, GUIDANCE AND ESTIMATION 16

Now, what about this terminal penalty? That is what I told you. I will talk about that. If you have a terminal penalty also, then what happens is, if you put t_f, X_f , then this part goes to 0 and you are left out with this part. So, what it tells us is just the boundary condition that will be differing, boundary conditions for V . If you do not have any terminal penalty, this happens to be 0. If you have some terminal penalty, then V of t_f, X_f happens to be that function.

Now, the **(())** tells us that if t_f goes to infinity, then what? Remember, many times we talked about infinite term **related** problems and things like that. So, then, t_f is fixed, but due to fixed infinity. So, if t_f goes to infinity, then **some relevant** results tell us that $\frac{\partial V}{\partial t}$ has to be 0. This is another useful kind of results. And, this if you analyze a little bit (Refer Slide Time: 22:20) here, $\frac{\partial V}{\partial t}$ equal to 0. And, let us imagine a case, where you have something like scalar problem; that means X is a single variable

sort of thing (Refer Slide Time: 22:29). In that case, if $\frac{\partial V}{\partial t}$ goes to 0, then what we have is an **ODE** equation.

This $\frac{\partial V}{\partial x}$ is nothing but only one state variable. And hence, this $\frac{\partial V}{\partial X}$ is nothing but $\frac{dV}{dX}$ in that case. So, you put it back; you get this **PDE**, results in ODE. So, that remains with that. This HJB equation, if you analyze little bit, this is $\frac{\partial V}{\partial t}$ here and then $\frac{\partial V}{\partial x}$ here. So, this is a non-linear **coupled** partial differential equation. So, this non-linear **coupled** partial differential equation is not easy to solve, but it results in that way. But, if $t \rightarrow \infty$, then this part is 0. And, if you have a similar problem, then it results in some set of ODE basically. What you also remember that ODE is not a linear ODE; that means that is typically a non-linear ODE for a non-linear problem. Anyway, we will see examples for that. So, this is the result (Refer Slide Time: 23:38). But, if $t \rightarrow \infty$, then $\frac{\partial V}{\partial t}$ is equal to 0.

(Refer Slide Time: 23:43)

Let us see an example, which will clarify our ideas a little bit.

(Refer Slide Time: 23:50)

Example – 1

Problem :

$$\text{Minimize } J = \frac{1}{2} \int_0^t (x^2 + u^2) dt \quad \text{subject to } \dot{x} = -x^3 + u, x(0) = x_0$$

Solution :

$$H = \frac{1}{2} (x^2 + u^2) + \lambda (-x^3 + u)$$
$$\frac{\partial H}{\partial u} = 0 = u + \lambda$$
$$u = -\lambda = -\left(\frac{\partial V}{\partial x}\right)$$

OPTIMAL CONTROL, GUIDANCE AND ESTIMATION 18

It is a very simple example sort of thing. You have a standard quadratic cost function starting from 0 to t $\int_0^t x^2 + u^2 dt$, subject to this non-linear system equation $\dot{x} = -x^3 + u$; initial condition is known. It is an unconstrained problem; that means **control early** is not confined to a particular set. So, let us start solving this. First thing is definition of Hamiltonian. Hamiltonian means l plus λ transpose f . l is half of this fellow; half goes inside. This is l plus λ times f ; f is nothing but this $-x^3 + u$. So, this one you put it back here; this l plus λ times f ; **there is a thing called** λ transpose here; λ is also scalar. And, the second result is this – because it is unconstrained, $\frac{\partial H}{\partial u}$ has to be equal to 0; that means...

Now, what is $\frac{\partial H}{\partial u}$? First term is nothing but u ; and, second term is nothing but λ . So, this 0 is equal to $u + \lambda$. So, what I get as solution is u equal to $-\lambda$; that is nothing minus $\frac{\partial V}{\partial x}$. So, the point here is if I give a solution for V as a function of state somehow, then I can do this partial derivative; I will get λ after that. And, once I put it back, negative of that is nothing but the control, equal to $-\lambda$; remember that. So, all that it matters is getting a solution for V . Let us see how to do that.

(Refer Slide Time: 25:34)

Example – 1 ...contd.

$$H_{opt} = \frac{1}{2}x^2 - \frac{1}{2}\dot{\lambda}^2 - \lambda x^3$$
$$= \frac{1}{2}x^2 - \frac{1}{2}\left(\frac{\partial V}{\partial x}\right)^2 - \left(\frac{\partial V}{\partial x}\right)x^3$$

HJB Equation: 

$$\frac{\partial V}{\partial t} - \frac{1}{2}\left(\frac{\partial V}{\partial x}\right)^2 - \left(\frac{\partial V}{\partial x}\right)x^3 + \frac{1}{2}x^2 = 0$$

with $V(t_f, X_f) = 0$

This is a partial differential equation (PDE)

OPTIMAL CONTROL, GUIDANCE AND ESTIMATION 19

Now, if I do that, you need to evaluate this H opt. H opt is likely... This is the Hamiltonian definition (Refer Slide Time: 25:42). But, remember, u is now like this; u is minus lambda and things like that. So, if you put it back, that is what I get as optimum Hamiltonian. When lambda by definition is nothing but del V by del x. So, wherever lambda is there, I will put del V by del x. So, the H opt is like this. So, in this particular example, the HJB equation tends out to be this. So, if I see this equation in V, there is a partial derivative with respect to time and there is a partial derivative with respect to x, which is also squared already here. So, essentially, this is it; this results in something like a non-linear partial differential equation, becomes difficult to solve.

And, also remember, on the way, this V of t f, X f is equal to 0, because there is no terminal penalty here. There is nothing here. So, that is 0. That is why this result comes (Refer Slide Time: 26:44) – V of t f, X f is equal to 0. Now, this is a PDE and it is difficult to solve. Here we introduce one more assumption; but, what about t f going to infinity? If t f goes to infinity, then obviously one of the results implies that del V by del v goes to 0. Now, this goes to 0. As I told you some time back, this (Refer Slide Time: 27:08) entire thing is nothing but an ODE.

(Refer Slide Time: 27:12)

Example – 1 ...contd.

However, since the above equation is difficult to solve as such, we wish to introduce further conditions in our attempt to get a state feedback solution. In this regard, we assume

$$t_f \rightarrow \infty, \text{ which implies } \frac{\partial V}{\partial t} = 0$$

Hence the HJB equation reduces to the following "ordinary differential equation(ODE)"

$$\left(\frac{dV}{dx}\right) + 2\left(\frac{dV}{dx}\right)x^3 - x^2 = 0$$

OPTIMAL CONTROL, GUIDANCE AND ESTIMATION 20

This particular ODE or ordinary differential equation can be written something like this. Still this is a nonlinear ordinary differential equation (nonlinear ODE). What you get is much simpler than this PDE (Refer Slide Time: 27:29); or, still it is a nonlinear ODE. So, how do you solve it? Solving it in closed form is also a trick situation for nonlinear ODEs. And, one of the ways to solve is something called cover series approximation and all that. So, let us in (()) that.

(Refer Slide Time: 27:47)

Example – 1 ...contd.

Note that since $\frac{\partial V}{\partial t} = 0 \quad \forall t, \quad V(t_0) = V(t_f) = 0$

The above equation is a nonlinear ordinary differetial equation, which is still difficult to solve exactly in the closed form. Hence, we attempt to obtain an "approximate" closed form solution, by using the power series approach.

OPTIMAL CONTROL, GUIDANCE AND ESTIMATION 21

Seriously, this is what I have already told (()) This is an ODE and still difficult to solve. And, what you are interested in is something like an approximate closed form solution. So, one of the way to explore is power series approach. So, let us explore that.

(Refer Slide Time: 28:06)

Example – 1 ...contd.

Let us expand $V(x)$ as a fourth-order power series as follows

$$V(x) \approx a_0 + a_1 x + \frac{a_2 x^2}{2!} + \frac{a_3 x^3}{3!} + \frac{a_4 x^4}{4!}$$

Then $\frac{dV}{dx} = a_1 + a_2 x + \frac{a_3 x^2}{2!} + \frac{a_4 x^3}{3!}$

Substituting the expressions for V and $\frac{dV}{dx}$ into the HJB equation and equating the coefficients of the powers to zeros, we $a_0 = a_1 = a_3 = 0$, $a_2 = 1$ and $a_4 = -6$.

OPTIMAL CONTROL, GUIDANCE AND ESTIMATION
Dr. G. B. ...

22

What you are telling here is let me write this V of x as something like five terms here. And, writing up to five terms, you can think that is not the way to get. What I am taking here is zeroth power; starting from zeroth power constant all the way up to fourth-order power. So, what I am expecting here is some sort of a good solution even though theoretically it is an approximate solution.

Now, what you need? If you see this (Refer Slide Time: 28:36) equation, we need an expression for $\frac{dV}{dx}$ by $\frac{dV}{dx}$ here as well as here. So, you put that expression $\frac{dV}{dx}$ by $\frac{dV}{dx}$; it is very easy; this term will be nothing, zero; this is a 1; this is a 2 x and all that. So, this $\frac{dV}{dx}$ by $\frac{dV}{dx}$ results in this term (Refer Slide Time: 28:52). Now, what you do is, we will not do the entire thing, but what is necessary here is $-\frac{dV}{dx}$ by $\frac{dV}{dx}$ is available now. Now, the HJB is equation is like this – this (Refer Slide Time: 29:07) equation. So, we put $\frac{dV}{dx}$ by $\frac{dV}{dx}$ whole square here, whatever expressions we are getting. And then, we try to kind of equate the various powers and then get a set of coefficient equations sort of thing (Refer Slide Time: 29:21). That I will leave it as some sort of no more exercise sort of thing.

What is needed is you got the expression from V and dV especially for dV by dx . That expression you take it and substitute it in the ODE, whatever ODE is here. Collect various powers of x ; and, remember, right side is 0. So, that means all coefficients have to be 0 (Refer Slide Time: 29:47). So, all coefficients will become functions of these constants, whatever constants you are having (Refer Slide Time: 29:52). And then, you will see that this will result in a set of equations in the parameters. These coefficients are parameters. And, if you solve that set of equations, this is what you will get. What you will get is a 0, a 1 and a 3. a 0, a 1 and a 3 – all these things are 0. a 2 is 1 and a 4 is minus 6. This exercise you can do it yourself and see. Now, once you do that, once you have it, then you got an expression for V and expression for dV by dx .

(Refer Slide Time: 30:29)

Example - 1 ...contd.

This leads to

$$\lambda = \frac{dV}{dx} = x - x^3$$

$$u = -\lambda = -x + x^3$$

Note that this is stabilizing since the closed loop dynamics is $\dot{x} = -x$

Handwritten notes:
 CL System
 $\dot{x} = -x^3 + u$
 $= -x^3 - x + x^3$
 $= -x$
 $\dot{x} = -x$
 $x(t) = e^{-t} x_0 \rightarrow 0$ as $t \rightarrow \infty$

NPTEL OPTIMAL CONTROL, GUIDANCE AND ESTIMATION 23

So, let us go and see that. Ultimately, what it leads to if I substitute it here (Refer Slide Time: 30:34). Let me do that probably. I have got V of x ; this is equal to ... First one remember, a 0, a 1 and a 3 are 0. So, that I am not taking. a 2 is 1. So, this is x square – a 2 is 1, remember that – by 2 factorial, is two; and, a 4 is minus 6. So, what I get is minus 6 x 4 divided by 4 factorial; so, that means 4 into 3 into 2 into 1 obviously (()) So, this 3, 2 – 6; this one is gone; this – what I am left out is something like x square by 2 minus x fourth divided by 4. Now, if I take dV ... This is V of x . If I take dV by dx , obviously, from this part of the story, if I take this expression, this turns out to be nothing but x minus – this 4 x (()) will go – so I am left out with x cube. This is what we will

get. Then, dV by dx ultimately is x minus x cube. That is the $(())$ what we are getting here.

Now, u turns out to be minus λ (Refer Slide Time: 31:52). So, what happens? u is nothing but minus x plus x cube. What is happening finally? The beautiful thing is we have got a state **figured control** even though it is a nonlinear optimal control problem to start with. And, we had no terminal **full empty**; and, t_f we assume to be infinity and things like that. Ultimately, it resulted in something likely a closed form expression for the controller. So, given a state, I can evaluate this control and I am done. That is the beautiful thing about the HJB equation in general dynamic programming.

Now, what? There is some interesting analysis that follows here. Let us see that also. We started with something like $\dot{x}$ is nothing but minus x cube plus u . Now, u is nothing but minus x . So, if I substitute this... This is the closed loop system. If I substitute this, which is minus x cube plus u and then that u is this one – so, I will substitute that, this is minus x plus x cube. This x cube gets cancelled out. So, what it results is $\dot{x}$ equal to minus x . And obviously, this is a linear equation essentially. And, with minus x , that means eigenvalue is minus 1. And hence, the system is stable. You can also very quickly realize that this is the solution, e to the power minus t into x naught. So, this goes to 0 as t goes to infinity. So, that means you got a solution, which is also stabilizing.

Now, there is another interesting argument here. Let me find it out all also. What you get here is (Refer Slide Time: 33:46) something like stabilized linear equation sort of thing. Somebody can also argue that **while** going through all these exercise, you go to this power series expression (Refer Slide Time: 33:59); here up to fourth-order term; **write** this partial derivatives. Put all the coefficients like in other equations, equate the coefficient; that exercises are not shown; equate all the coefficients to 0; solve the equations, find the coefficients and then do this analysis to get it there (Refer Slide Time: 34:13). Ultimately, what it is giving? It is giving something like a stable linear aerodynamic sort of thing.

There if you **$(())$ know to derivate** an equation; and, those who do not know, you can see the other course. There are lectures on that. They also very well argue that I can derive this equation (Refer Slide Time: 34:33) coming from dynamic inversion sort of ideas by enforcing this equation to begin with. How do I do that? Let me see that; can I not solve

like control $(())$; that means I start from this equation. And, this equation will give me that this is the **derived** $\dot{x}$. But, the $\dot{x}$ is nothing but $-x^3 + u$; that is the $\dot{x}$. That is something like $-x$. That is what this equation is giving. So, u is nothing but $-x + x^3$; exactly, what I got here. Whatever I got here (Refer Slide Time: 35:20) is same as what I got here. And, here it is just a two line expression. I start with this expression $\dot{x}$ equal to $-x^3 + u$. And, this is the derived $\dot{x}$; **but, the actual $\dot{x}$ is up to $-x + u$ plus**. You have to substitute that; **and, that solves the control into line.**

(Refer Slide Time: 35:41)

**The Example Problem:
An Observation**

The expression for the controller obtained can be very easily obtained from the feedback linearizing (dynamic inversion) design. In that case, the problem formulation is to design a controller u such that the following stable error dynamics is satisfied

$$\dot{x} + kx = 0, \quad k > 0$$

Substituting for $\dot{x} = -x^3 + u$, assuming $k = 1$ and solving for the control we get

$$u = -x + x^3$$

NPTEL OPTIMAL CONTROL, GUIDANCE AND ESTIMATION 24

That is what I have written here. You start with something like a stable... desired dynamics sort of thing. You substitute k equal to 1 and then substitute $(())$ and get it very quickly; results in the same thing.

Now where is the problem here? The problems are somewhat like this. This (Refer Slide Time: 35:58) particular solution that you are looking here is really not a good solution. In other words, it is a stabilizing solution; it will do the job, but if you are a little bit clever or something, you can also see that this control expression what you are getting here is cancelling out the beneficial nonlinearity. We will see this in this theory lecture also. So, $-x^3$ is beneficial nonlinearity, because any **terms**, $\dot{x}$ equal to negative of x to the power n as long as n is odd – this is the stable dynamic, because if I take Lyapunov function, V of x equal to half x^2 and I get $\dot{V}$, it is nothing but x into $\dot{x}$; x

into $\dot{x}$ is nothing but minus of x to the power n plus 1. We can write it clearly. Whatever I am getting here is minus of x to the power n plus 1. If n is odd, then n plus 1 is even; and then, minus of that is certainly going to be something like a negative definite function.

If you see this analysis, it tells us that minus x cube what was here was stabilizing term. And, by doing all these, we have cancelled out that beneficial nonlinearity. Why it happened is because of what we thought that fourth-order power series approximation is going to do that job is not. So, if you really want to have a very good solution, probably, you could have continued up to something like twentieth order or things like that. Even people do sometimes more than that. Now, if you do that, then all the elegance is lost. In other words, even if you take away five coefficients, the algebra involved, which I did not show here, is quite a bit. Now, if you have more and more number of coefficients, the algebra involved will be more and more. So, even for a simple scalar problem, you can realize what kind of algebra difficulties we get into.

(Refer Slide Time: 38:35)

**The Example Problem:
An Observation**

- The “dynamic inversion” controller is nothing but the same truncated optimal control solution. Hence, truncated power series approximate optimal control solutions are not that elegant, unless a large number of terms are considered in the power series. However, a large number of terms increase the algebraic and computational complexity.
- Like dynamic inversion, the approximate optimal controller has cancelled the “beneficial nonlinear term) in the system dynamics. A good optimal control solution should have kept this term in the closed dynamics.

OPTIMAL CONTROL, GUIDANCE AND

We have some comments; I can think about. This is the observation comments and things like that. So, what I told already is summarized here. The dynamic inversion control is nothing but the same truncated optimal solution. And hence, the truncated power series approximate optimal control solutions are not that elegant, unless a large number of terms are considered in the power series. That is what I told you. Instead of

fourth order term, probably, you could have taken tenth order, fifteenth order, like that, twentieth order, things would have been better. But, a large number of terms increase the algebraic and computational complexity. So, just blindly having more and more terms in the power series, is better for the solution property. But, it will also give us lot of **ethics** **for** getting the solution.

And, as I also told you, like dynamic inversion, the approximate optimal controller has cancelled the beneficial nonlinearity – minus x cube term. And, a good optimal control solution should have kept this term in the closed loop dynamics. We will also see that how it is possible and all that, how is possible to do that.

(Refer Slide Time: 39:51)

Example – 1: Alternate Approach

Problem:

$$\text{Minimize } J = \frac{1}{2} \int_0^{t_f \rightarrow \infty} (x^2 + u^2) dt \text{ subject to } \dot{x} = -x^3 + u, x(0) = x_0$$

Solution:

$$H = \frac{1}{2} (x^2 + u^2) + \lambda (-x^3 + u)$$

$$\frac{\partial H}{\partial u} = 0 = u + \lambda \quad \Rightarrow \quad u = -\lambda$$

$$H_{opt} = \frac{1}{2} x^2 - \frac{1}{2} \lambda^2 + \lambda (-x^3)$$

This region – this takes me to different approach. Different approach in the sense, this is my own observation; why the difficulty happened in my own observation is, because we wanted to solve for V. Remember, this (Refer Slide Time: 40:07) HJB equation; whatever you are telling is ultimately in **equation 1** in terms of V. So, we attempted to solve for the variable V, which is optimal cost. However, if you just see a little bit more, all other control is a function of lambda, either x or lambda. And, lambda is nothing but del V by del x. So, why unnecessarily going ahead in solving for V, instead you can just simply solve for del V by del x; and, we have done, because our control is ultimately function of del V by del x as you know that; it is not x and V. So, we stop at the equation, where you just simply solve for del V by del x and then we will see what

happens. I will give you one example; and, the extension of that example also **let us see**. In the same example that we have been talking about, this is exactly the same equation and things like that; same example. Here u is again minus lambda; and, H_{opt} is this.

(Refer Slide Time: 41:09)

Example - 1: Alternate Approach

It is an infinite-time problem. Hence, the HJB equation is

$$H_{opt} = 0$$

$$\frac{1}{2}x^2 - \frac{1}{2}\lambda^2 + \lambda(-x^3) = 0$$

$$\lambda^2 + 2(x^3)\lambda - x^2 = 0$$

$$\lambda = \frac{1}{2} \left[-2(x^3) \pm \sqrt{(2x^3)^2 + 4x^2} \right] = -(x^3) \pm \sqrt{x^6 + x^2}$$

Hence $u = -\lambda = x^3 \mp \sqrt{x^6 + x^2}$

NPTEL OPTIMAL CONTROL, GUIDANCE AND

We have H_{opt} equal to 0. And, get this equation. The problem here is... The previous approach was we substituted for lambda, that is, δV by δx and attempted to solve for V as a power series in fact. Instead of that, we want to solve for δV by δx , which is nothing but lambda. So, what I will do is I will interrupt you at this equation, what I am getting here, is something like a quadratic expression for lambda. And, this is nothing but a quadratic equation. So, I get the solution, lambda is nothing but this minus V plus or minus V square minus 4 **ac**, all that by 2. If I put it there, what I am getting is something like this. So, the control is ultimately minus lambda; remember that the control is minus lambda (Refer Slide Time: 41:56). And, lambda is **(())** is a function of state. There is a little bit **ambiguity** here, which we need to resolve. So, what we are having here is u equal to minus lambda, is nothing but... lambda is this; so, minus lambda is x cube – this is plus or minus or minus or plus – either way. So, what it tells us? We have to select now. We have two possibilities here and we select. So, what you may claim here is we just select the negative one.

(Refer Slide Time: 42:26)

Example – 1: Alternate Approach

We select,

$$u = x^3 - \sqrt{x^6 + x^2} \quad \text{for a stabilizing solution}$$

Proof:

Let us select a Lyapunov function $V(x) = \left(\frac{1}{2}\right)x^2$.

NPTEL OPTIMAL CONTROL, GUIDANCE AND ESTIMATION 28

We select this negative term out of this plus or minus or minus or plus; I claim. And, if you select the minus term, it is good; it is also a stabilizing solution. This expression you can **never get it as** power series expression. This expression is coming out naturally from this equation here. So, this is what it is for a stabilizing solution. And, let us select the Lyapunov function. How do you prove that again that this is stabilizing solution? So, we select this standard Lyapunov equation. And, all that we need to show is $\dot{V}$ is negative definite.

(Refer Slide Time: 43:06)

Example – 1: Alternate Approach

Then,

$$\begin{aligned} \dot{V} &= x\dot{x} = x[-x^3 + u] \\ &= x[-x^3 + x^3 - \sqrt{x^6 + x^2}] \\ &= -x^2\sqrt{x^4 + 1} \quad (\text{A negative definite function}) \end{aligned}$$

Moreover, this result is valid globally
and $V(x)$ is a "radially unbounded function" as well.
Hence, the closed loop system is "globally asymptotically stable".

NPTEL OPTIMAL CONTROL, GUIDANCE AND ESTIMATION 29

If V of x is half x square, then $\dot{V}$ is nothing but x times $\dot{x}$; $\dot{x}$ is minus x cube plus u . I remember u , you have selected it as something like this expression (Refer Slide Time: 43:17). So, I can substitute u as this expression here (Refer Slide Time: 43:19). And then, minus x cube plus x cube gets cancelled out. So, we are left out with this one. And obviously, there is a positive square root of this; this is positive term always; this is always positive term and there is a negative sign here. So, $\dot{V}$ happens to be negative a definite function.

By Lyapunov theory, it tells us that this (Refer Slide Time: 43:44) is a positive definite function and $\dot{V}$ is a negative definite function. And hence, what I get is a stabilizing solution, rather asymptotically stable solution sort of thing. And again, those of you know a little bit of Lyapunov theory... And, if you do not know, you can see my other course here. There are I think 2-3 lectures on Lyapunov theory itself. So, what it tells you is V of x is positive definite and $\dot{V}$ is negative definite function. Then, it is asymptotically stable. But, it goes a little bit more than that. Then, V of x is radially unbounded, because as you go radially away, the function has to be away and away; this kind of thing (Refer Slide Time: 44:34). So, x and V of x . There is no saturation sort of thing. So, it is something like radially unbounded.

And, this function (Refer Slide Time: 44:45) is globally defined. V of x is globally valid – half of x square. And, $\dot{V}$ what we are getting it is also globally valid. This negative definite is not confined to a particular region and all that. So, V is globally positive definite; $\dot{V}$ is globally negative definite. And, on top of that, this V of x is radially unbounded. So, this Lyapunov region tells us that whatever results we are getting is global; that means this closed loop system is guaranteed to be globally asymptotically stable. So, this is the power of this HJB theory and all that.

If you are able to get a solution, there are certain very need properties as you said we got. And also, remember, this particular solution that you are getting here will not cancel the beneficial nonlinearity. This we put it here (Refer Slide Time: 45:42) or else, closed loop solution – it is not there; but, I can derive it; that is not the problem. u is like this; so, $\dot{x}$ is nothing but minus x cube plus u . So, what it results in is minus... one x cube and minus x cube will go; and, this results in something like minus x sixth plus x square; that means if I take out this one – one x , minus x into something like x fourth plus one and all that. So, this closed loop system has this property of this not cancelling the beneficial

nonlinearity **property**. It results in a nonlinear closed loop system, which is nonlinear, but globally asymptotically stable. That is of the more important thing – this term (Refer Slide Time: 46:39).

(Refer Slide Time: 46:44)

This example 2 is now the extension of example 1. And, I want to say that... somebody should not think that this has become only minus x cube there and hence it is happening around that.

(Refer Slide Time: 46:56)

Example-2

Problem:

$$\text{Minimize } J = \frac{1}{2} \int_0^{t_f \rightarrow \infty} (x^2 + u^2) dt \text{ subject to } \dot{x} = x - x^3 + u, x(0) = x_0$$

Solution:

$$H = \frac{1}{2}(x^2 + u^2) + \lambda(x - x^3 + u)$$

$$\frac{\partial H}{\partial u} = 0 = u + \lambda \quad \Rightarrow \quad u = -\lambda$$

$$H_{opt} = \frac{1}{2}x^2 - \frac{1}{2}\lambda^2 + \lambda(x - x^3)$$

And, also remember in my (()) lecture, I have already pointed out that point of time that this is a one solution that we like to derive ourselves. So, this is the problem; same problem. We have a quadratic cross function subject to this nonlinear dynamics. Now, you should have simply minus x cube; we have x minus x cube. And also remember, this particular problem, this infinite time quadratic regulator with this non-linear system dynamics, where x is a scalar has become a benchmark example in literature; that means if you have any new technique that you claim that you can solve some nonlinear control problem, optimal control problems and things like that, then probably, this is one problem that you would like to try out first. And, we will see that in many cases including (()) optic critic and all that, going back this equation again and again.

The same approach we will follow. We will first construct the Hamiltonian. Hamiltonian is l plus λ transpose f . So, l is this part (Refer Slide Time: 47:58) – half of this term; and, λ times f ; f is this; it is not only minus x cube, but plus x cube is also there. So, as I told you in the yesterday's lecture, there is a nice interesting thing that goes on here. Remember, both are odd powers x to the power 1 – odd; minus x to the power 3, which is odd and so. So, this term is a positive coefficient; this term is a negative coefficient; that means this term is destabilizing; whereas, this term is stabilizing. And, if the modulus of x is less than 1, that means x is bounded between minus 1 and plus 1. Then, x to the power cube is very small; that means within that domain, minus 1 to plus 1, this term is less dominating compared to this; that means this will try to destabilize the system.

However, when modulus of x is greater than 1, this x cube is (Refer Slide Time: 48:55) getting amplified there; that means our system dynamics, this stabilizing part becomes dominating; that means beyond x equal to that modulus of x equal to 1, that means... I will leave that; it is self explanatory anyway. So, beyond this bound between minus 1 to plus 1, this term is dominating, which will pull the system backwards, try to kind of lead the trajectory towards 0. But, as soon as the x value starts, it becomes lesser than 1; it falls between that zone of minus 1 to plus 1. This term becomes powerful and this is destabilizing (()) So, this funny dynamics goes on here.

Once the longitude is larger, say if the system property is stable... I am talking about homogeneous system without control x n obviously. But, once it is close to 0, it is destabilizing. Again, it poses (()) So, unless the control is good, we will never go to 0;

the regulator problem will never be happening here, because close to 0, there is a destabilizing term. And, they are the reasons why it is also a kind of a benchmark problem. First, you will notice by the (()) Anyway, coming back to this, we have a Hamiltonian definition. So, del H by del u is again... That term is not part of... So, we have 0 equal u minus u plus lambda; so, u equal to minus lambda. What we are having here is H opt, is optimal Hamiltonian is something like this. Once you substitute u equal to minus lambda, you get something like that. So, again, t f goes to infinity and there is no terminal penalty here.

Refer Slide Time: 50:52)

Example-2

It is an infinite-time problem. Hence, the HJB equation is

$$H_{opt} = 0$$

$$\frac{1}{2}x^2 - \frac{1}{2}\lambda^2 + \lambda(x - x^3) = 0$$

$$\lambda^2 - 2(x - x^3)\lambda - x^2 = 0$$

$$\lambda = \frac{1}{2} \left[-2(x - x^3) \pm \sqrt{2^2(x - x^3)^2 + 4x^2} \right]$$

NPTEL OPTIMAL CONTROL, GUIDANCE AND

Del V by del t is 0. And then, what we will land up with is something this – H opt is equal to 0; and, H opt – already, we have got it in this form. So, this is what it is. Again, this happens to be a quadratic equation in terms of lambda. Again, we solve for lambda directly like the previous example. All that we are having is this additional term here.

(Refer Slide Time: 51:20)

Example-2

$$\lambda = (x - x^3) \pm x\sqrt{(1 - x^2)^2 + 1}$$

Hence $u = -\lambda = -(x - x^3) \mp x\sqrt{(1 - x^2)^2 + 1}$

We select,

$$u = -(x - x^3) - x\sqrt{(1 - x^2)^2 + 1} \text{ for a stabilizing solution}$$

Stabilization of closed loop dynamics:

Let us select a Lyapunov function $V(x) = \left(\frac{1}{2}\right)x^2$.

OPTIMAL CONTROL, GUIDANCE AND ESTIMATION

So, what we are getting here is lambda equal to that. And hence, u equal to minus lambda. This is complicated looking expression sort of thing. But, again, if I take a negative sign instead of positive sign, that will result in a stabilizing solution. And again, the similar set of proof can be followed. Let us see very quickly, V of x is again that way. So, V dot of x is (Refer Slide Time: 51:41) x times x dot; and, x dot is this expression (Refer Slide Time: 51:48) - x minus x cube plus u; so, I can substitute it back there. So, I substitute back. Remember, u equal to this expression already (Refer Slide Time: 51:58). So, whatever u we are getting, we can substitute it there.

(Refer Slide Time: 52:03)

Example-2

Then,

$$\begin{aligned} \dot{V} &= x \dot{x} = x[(x - x^3) + u] \\ &= x[(x - x^3) - (x - x^3) - x\sqrt{(1 - x^2)^2 + 1}] \\ &= -x^2\sqrt{(1 - x^2)^2 + 1} \quad (\text{A negative definite function}) \end{aligned}$$

Moreover, this result is valid globally
and $V(x)$ is a "radially unbounded function" as well.
Hence, the closed loop system is "globally asymptotically stable".

OPTIMAL CONTROL, GUIDANCE AND ESTIMATION

34

So, $\dot{x}$ into $\dot{x}$ dot; $\dot{x}$ dot contains this term plus u . Again, u is **that** term already; so, this term (Refer Slide Time: 52:08) with a negative sign here. So, we substitute all that; and, we can rewrite this expression $\dot{V}$ as something like this. Again, this term is a quadratic function. So, this is always positive for x not equal to 0. And, this is also with a minus into x square sort of thing. So, $\dot{V}$ is a negative definite function. And, again, this approach to be globally valid; and again, this V of x is radially unbounded; that means once again, we will land up with the situation, where this control that we are telling is this expression. And hence, it is a closed form expression as this particular state feedback optimal control solution will result in globally asymptotically closed loop system – globally asymptotically stable closed loop system. So, that is the power of this HJB equation and all that.

This small example and an extension of (Refer Slide Time: 53:10) this, where **you go (()) this to** small example demonstrate the usefulness of HJB equation. However, in general, it may not be a very good technique for getting the solutions this way. My suggestion is globally, if you can do it, there is a **(())** term should be towards this. But, if you cannot do it, there are many techniques getting double opt and also double opt already, which will try to exploit the HJB equation to get something like an approximate solution and all that. We have seen one solution for theta d approach and all that in the last class.

(Refer Slide Time: 53:47)

Dynamic Programming: Some Important Facts

- Dynamic programming is a powerful technique in the sense that if the HJB equation is solved, it leads to a “state feedback form” of optimal control solution.
- HJB equation is both necessary and sufficient for the optimal cost function.
- At least one of the control solutions that results from the solution of the HJB equation is guaranteed to be stabilizing.

OPTIMAL CONTROL, GUIDANCE AND ESTIMATION
Dr. G. D. Venkatasubramanian, IIT Bombay

35

Some important facts are something like this. In general, there are generic facts. First thing is like this. The dynamic programming is a very powerful technique in the sense that if HJB equation is solved, it leads to a state feedback form of optimal control solution. Another technique gives that. And, what you are looking at is something like a tunnel of solutions together; that means $((\cdot))$ t naught and x naught can fall in from a domain of values. And, I am ready with the control solutions for that. So, that is the power of HJB equation.

HJB equation also tends out to be both necessary and sufficient; that means so far we are not talked out sufficiency conditions and all that in calculus a variation approach; we always talked about necessary conditions only. But, HJB equation **tells us**, there it is both necessary as well as sufficient. The next one is – what it tells us, even though this HJB equation is a non-linear PDE in general and hence it can throw multiple solutions and all that, it tell us that at least one of the control solutions that results from the solution of HJB equation is guaranteed to be stabilizing. We have seen that example like we took from Lyapunov function, positive definite, so that $\dot{V}$ is negative definite and all that. But, it **tells us** that these results are quite valid in general while it tells us at least one of the control solution that results from the solution of HJB equation guaranteed to be stabilized; that means we do not want to keep on searching and all that. Within the finite set of solutions that we have, we explore which is the solution that is stabilizing and we are done.

(Refer Slide Time: 55:37)

Dynamic Programming: Some Important Facts

- The resulting PDE of the HJB equation is extremely difficult to solve for in general.
- Dynamic Programming runs into a “huge” Computational and storage requirements for reasonably higher dimensional problems. This is a severe restriction of dynamic programming technique, which Bellman termed as “**curse of dimensionality**”.

OPTIMAL CONTROL, GUIDANCE AND ESTIMATION 36

Further things, the difficulty part is rather like this. The resulting PDE from the HJB equation is extremely difficult to solve in general. There are that I have been pointing out consistently. And, suppose you want to solve it numerically, there are numerical attempts also to solve this HJB equation numerically. It runs into the huge computational and storage requirements for reasonably good practical problems. And, this tends out to be a severe restriction of the dynamic programming in general, which Bellman himself termed as something like curse of dimensionality; that means if the number of states are increased for the duration of the control application t_{naught} to t_f , that is, more, then it runs into this huge computational and storage requirements. In other words, the computational complexities in the form of exponential. That is what Bellman termed it as some curse of dimensionality. Remember, the calculus of variation, we had this curse of complexity. The $(())$ problem and all that lead to curse of complexity. Here it will lead to curse of dimensionality. Both are equally varied in a way.

For next classes and all, we will see how to kind of address this curse of dimensionality in a limited sense at least or in a reasonably good way, so that we will get the benefits of this HJB equation without running into these difficulties. That will result in this approximate dynamic programming, new network based adopted critic solutions and all that. We will see that in the next class anyway.

OPTIMAL CONTROL, GUIDANCE AND ESTIMATION

37

With that, I will list out a few references here. Most of my material here is taken from this first book. And, some of the examples I have solved it myself – this benchmark example especially. And then, always, you can refer to Bryson and Ho; this is the very standard book; there is also a small chapter on dynamic programming. But, my derivation is taken from Sage. Then, all these things are available. These two things are available as a very good sort of papers, which are survey papers in a way. This is survey of dynamic programming and computational procedures, very old paper, 1967 sort of thing.

And, of late, recently, this is also another one, which talks about nonlinear optimal control of washing machine based on approximate solution of HJB equation. It results in a closed form expression. But, the closed form expression is a very high order – fortieth term, fiftieth term – fiftieth order and things like that; very interesting. What I suggest that you can read and probably try to kind of experiment yourself (()) previous (()) With that, I will stop. Thanks for the attention.
