Lecture 23

Conventional Label-based Detection Techniques for Protein Microarrays

Welcome to the MOOC NPTEL course on interactomics. In today's lecture, we will discuss about label-based detection techniques. Most microarray applications developed till date extensively uses label-based detection techniques due to the advantages such as ease of use, common availability of reagents and simple instrumentation required for quantitation. Conventionally, these label-based techniques are fluorescence, radioactivity, chemiluminescence but gradually several new techniques like quantum dots, core Nano particles dye-doped nano-particles as well as different types of Raman based labels have also been employed for certain microarray applications. In proteomics applications, there is a need to detect a very dynamic range of proteins those which are present in low abundance as well as in the high abundance.

(Refer Slide Time: 1:55)

Lecture Outline

Conventional label based detection techniques for Protein microarrays

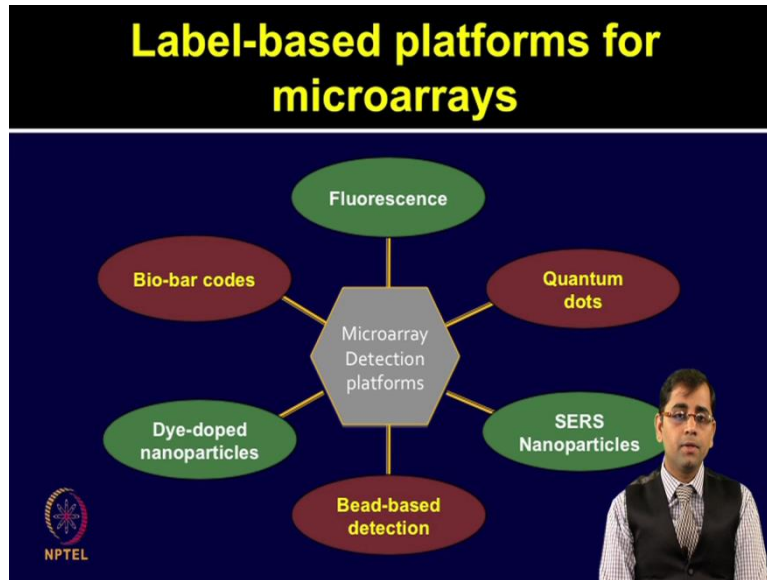

- Chromogenic detection techniques
- Chemiluminescence based detection
- Radioactivity based detection
- Fluorescence based detection

NPTEL

It is very easy to detect high abundant proteins but detection of very low abundant proteins requires sensitive detection platforms. In today's lecture, we will talk about different types of detection platforms focusing more on the conventional label-based detection techniques. There are several conventional label-based systems, popular among those are chemiluminescence, chromogenic based detection, radioactivity and fluorescence. In microarray detection systems, have improved significantly in the last few years. The sensing

technologies aim to improve the sensitivity, limit of detection, dynamic range and try to incorporate high resolution multiplexing capabilities. So, broadly we can group these detection platforms into label-based and label-free detection systems.

(Refer Slide Time: 3:01)

In today's lecture, we will talk about conventional label based systems and discuss each of these platforms in detail and in the next lecture we will move on to more recently developed advanced platforms used for the label-based detection systems.

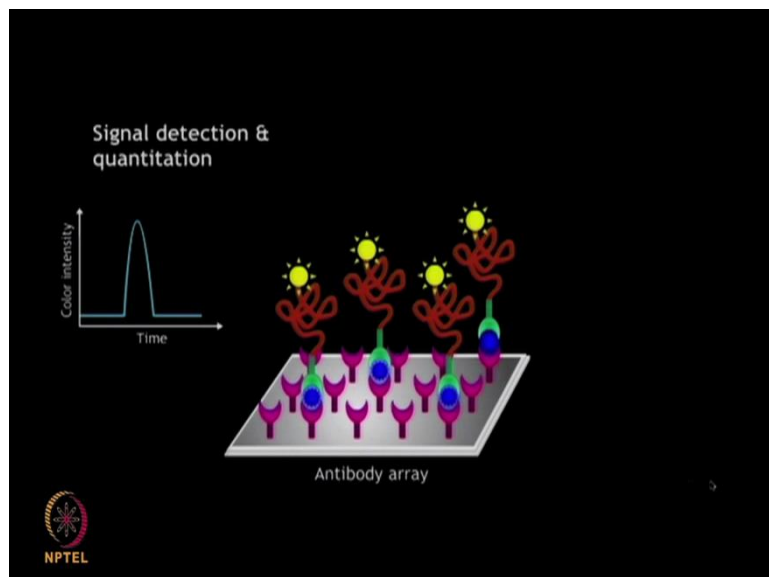

(Refer Slide Time: 3:46)

The antigen antibody interactions can easily be detected by chromogenic reactions. A chromogenic substrate is a molecule which is catalyzed by the enzyme link to the antibody to

provide a colored product which can be easily detected. In chromogenic detection, an enzyme that can give a colored reaction upon addition of suitable substrate is usually linked to the secondary antibody. Catalysis of chromogenic substrate molecules result into the colored product formation which can be easily detected and quantified by means of a microarray scanner.

(Refer Slide Time: 4:31)

Chromogenic detection, the antigen-antibody binding interaction can easily be detected by means of chromogenic reactions and enzyme that can give a colored reaction upon addition of suitable substrate molecules is linked to the secondary antibody, this acts as a probe by binding to a different epitope on the same antigen from that of the primary antibody bound to

the array surface. Binding of the substrate molecule results in the colored product being formed, which is easily detected and quantified by means of a microarray scanner.

(Refer Slide Time: 5:31)

Points to Ponder:

- Chromogenic detection, easy and cost effective mode of detecting protein interactions
- Antibodies detect interacting query proteins
- Substrates are catalyzed by the enzyme linked to antibody to provide a coloured product which can be easily detected, confirming interactions
- This technique is quantitative at femtomolar levels

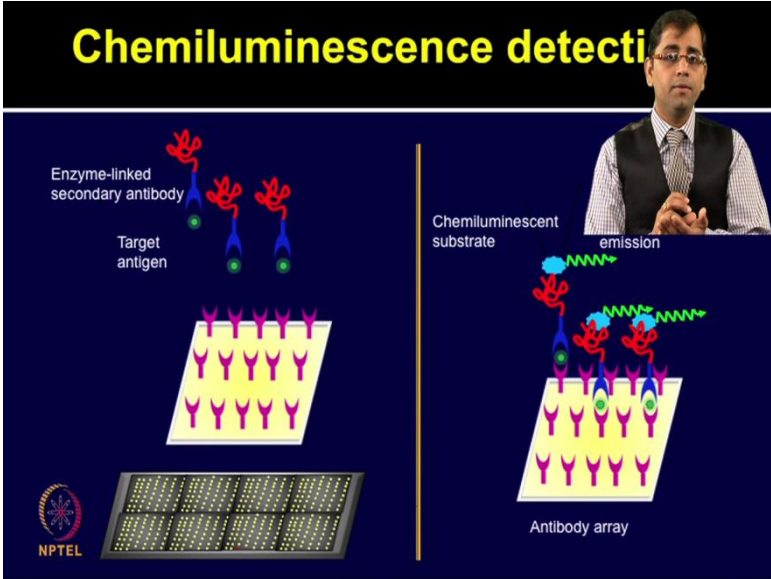

Quantitated colorimetrically by means of an array scanner

Let us now discuss, the chemiluminescence based detection system. The emission of light as a result of chemical reaction is referred to as chemiluminescence and this phenomenon can be used very extensively to detect molecules of interest, for example, luminol is used to detect trace quantities of iron of hemoglobin molecule.

(Refer Slide Time: 6:47)

Chemiluminescence detection

Enzyme-linked secondary antibody

Target antigen

Chemiluminescent substrate

emission

Antibody array

Similar chemical interactions between the target analyte and the probe molecule can be used for detection binding interactions for microarrays. The horseradish peroxidase HRP link antibodies are most commonly used to catalyze the reaction of chemiluminescent substrate molecules. In the given experiment, the antigen of interest binds to the corresponding antibody, which is coated on the microarray surface. Microarrays can then be probed by an enzyme linked antibody, which recognizes an epitope on the antigen, the excess antibody which is unbound can be washed off and the chemiluminescence substrate is added which reacts with enzyme and emits the light signal. Let us watch this animation on chemiluminescence detection system to understand its concept and mechanisms.

(Refer Slide Time: 7:39)

The antigen of interest binds to the corresponding antibodies which are coated on the microarray surface. The array is then probed by an enzyme linked secondary antibody that is capable of recognizing a different epitope on the same antigen. The excess unbound antibody is washed off and the chemiluminescent substrate is then added which reacts with enzyme and emits a light. This is detected by a means of CCD camera and a plot is obtained as shown on the right hand side, a graph is plotted between time and luminescence.

(Refer Slide Time: 8:49)

Points to Ponder:

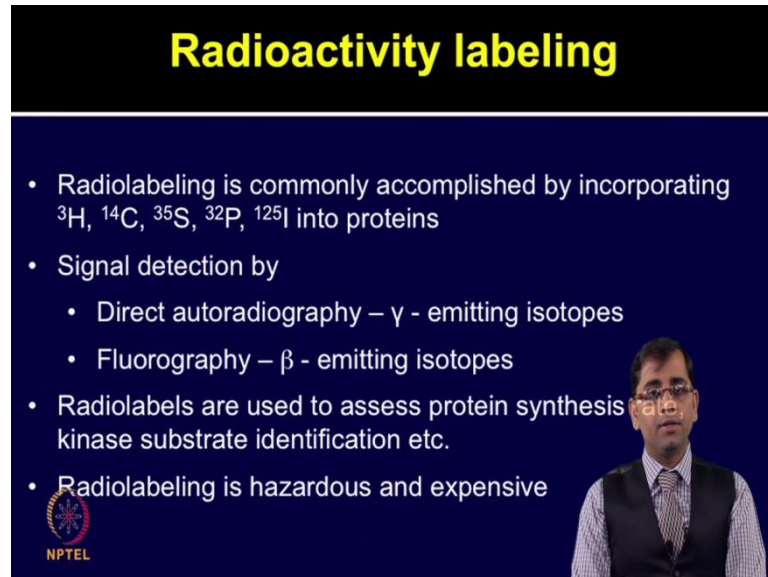

- On protein interaction, the query protein antigen is detected using antibody conjugated with enzyme like horse radish peroxidase (HRP)
- HRP is commonly used to catalyze the reaction of chemiluminescent substrate molecules which emits light
- A CCD based scanner is used to quantify the light signals emitted on catalysis and is plotted

NPTEL

We will now discuss the radioactive labeling. Radioactivity is a process by which certain elements spontaneously emit energy in the form of waves or particle by this integrating the unstable atomic nuclei into a more stable form. These radiations can be detected by autoradiography or a geiger counter. There are various biological applications of radio-

labeling like detection of antigen-antibody, protein-protein, protein-DNA and protein-RNA interactions on microarray surface, where binding can be studied through emission of radiation on binding of query protein on antigen to the corresponding target molecule.

(Refer Slide Time: 10:00)

Radioactivity labeling

- Radiolabeling is commonly accomplished by incorporating ^3H , ^{14}C , ^{35}S , ^{32}P , ^{125}I into proteins
- Signal detection by
 - Direct autoradiography – γ - emitting isotopes
 - Fluorography – β - emitting isotopes
- Radiolabels are used to assess protein synthesis, kinase substrate identification etc.
- Radiolabeling is hazardous and expensive

NPTEL

The slide features a video inset of a man in a suit and glasses speaking, positioned in the lower right corner. The NPTEL logo is located in the bottom left corner of the slide content area.

In radioactivity detection various types of radioactive molecules are used. These commonly used radiolabels include 3 hydrogen, 14 carbon, 35 sulphur, 32 phosphorus, 125 iodine or other radiolabels into the proteins. The signal detection can be recorded by direct autoradiography, which emits the gamma emission or be fluorography which emits the beta emission. The radio labels have also been used to assess the protein synthesis rate as well as other applications. Although, this is a very robust system, the radio labeling is hazardous as well as expensive. Mainly due to the hazardous nature of these radiolabels, this technique is used only for very essential studies; however the sensitivity and various type of applications unique to the radiolabels provide unique opportunity for this labeling strategy to be used for microarray applications. Let me show you this animation on radioactivity ignition system to give you a better understanding of how to use the radiolabels for microarray based detection system.

(Refer Slide Time: 11:46)

The array surface is coated with the protein mixture containing the target protein of interest. The suitable radio labeled query protein that can specifically interact with the protein of interest is used to probe the array surface. Once binding has occurred, the excess unbound query protein is washed off the surface.

(Refer Slide Time: 12:18)

The washed off array surface is then develop in an autoradiography solution. Beta emissions from the radioactive carbon atoms of the query protein strike the photographic film on which the final image is then developed.

(Refer Slide Time: 12:58)

Points to Ponder:

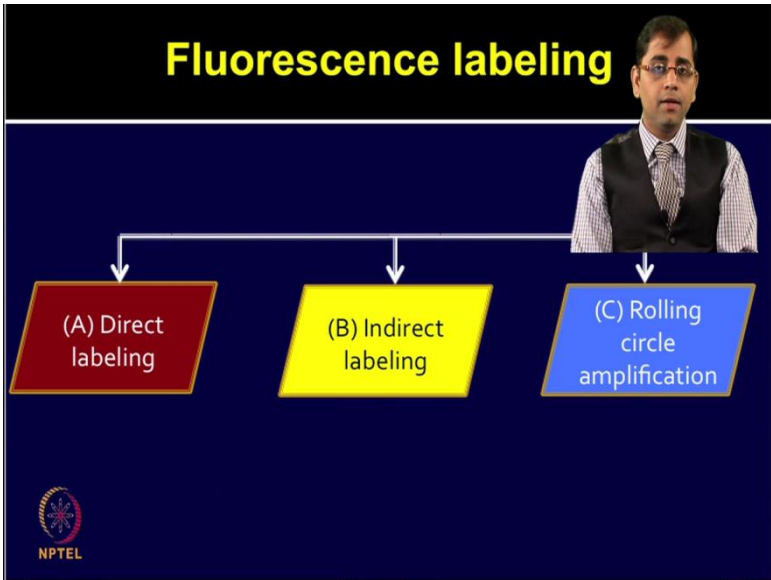

- Radio-labeled query protein on binding to an antigen gives out radiation
- Radiations are normally labelled using ^3H , ^{14}C , ^{35}S , ^{32}P , ^{125}I labels
- Signal detection can be performed by direct autoradiography which emits the γ -emission or by fluorography which emits the β -emission or can be detected using Geiger counter
- This technique is hazardous and expensive but highly sensitive

Let us now discuss the fluorescence labeling. Fluorescence is a phenomenon by which a substance absorbs radiation of one wavelength and emits another usually the longer wavelength and that is known as fluorescence. The fluorescent labels can be used to tag the probe molecule which binds to the analyte of interest on microarray surface. The excess fluorescent labels can be washed off from the microarray surface and the fluorescence from the binding interactions can be used to identify as well as quantify the target molecules.

(Refer Slide Time: 14:07)

Fluorescence labeling

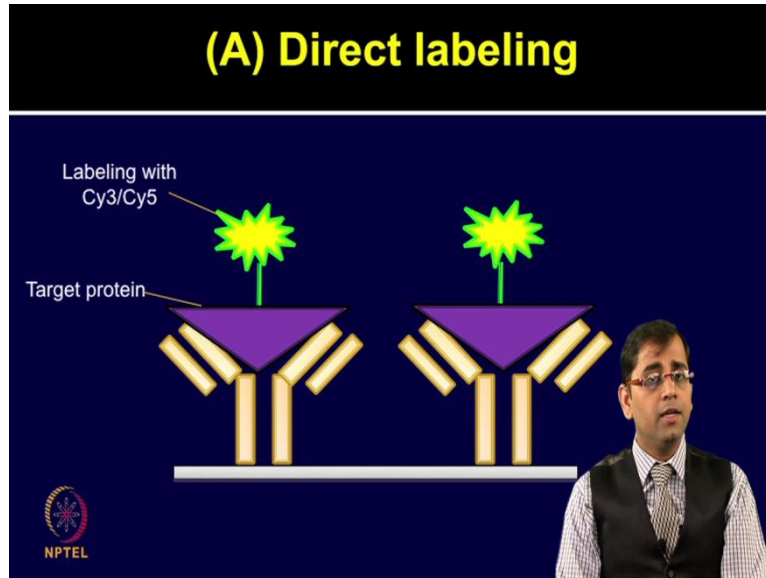

- (A) Direct labeling
- (B) Indirect labeling
- (C) Rolling circle amplification

Different types of fluorescent labeling methods have been employed for protein microarray based application which includes direct labeling, indirect labeling and rolling circle

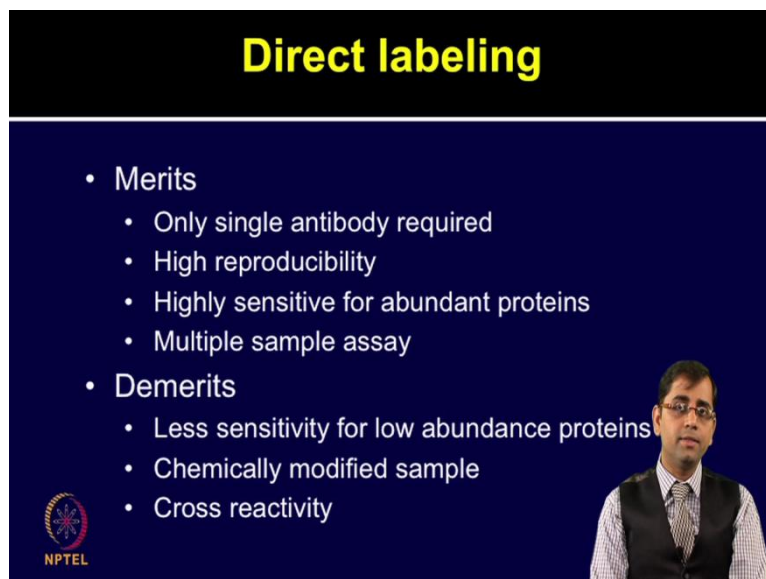

amplification, I will talk about these three methods in detail. Let us first talk about direct labeling method.

(Refer Slide Time: 14:23)

In direct labeling, the target protein is labeled directly with a fluorophore. Commonly used fluorophores include Cy3 or Cy5. Fluorophore is captured by immobilized antibody on the microarray surface. A direct labeling allows the co-incubation of reference sample or control sample with an analyte of interest, so that both containing different tags Cy3 and Cy5 can facilitate internal normalization.

(Refer Slide Time: 15:03)

Direct labeling method has many advantageous which requires only single capture antibody, it has capacity of multiplexed detection of 100s of analytes. It offers accuracy and reproducibility which is required for abundant proteins. However, it has several disadvantages as well, it is less sensitive for low abundant proteins, chemically modified samples are used and there is some chance for cross reactivity.

(Refer Slide Time: 15:40)

We will now discuss about indirect labeling. In indirect labeling method, the unlabeled target molecules are captured by antibodies which are immobilized on microarray surface. Detection is carried out by secondary antibody which is attached to a fluorophore molecule. The indirect labeling method offers higher sensitivity due to the binding of two target antibodies at different epitopes to the analyte of interest and high sensitivity because of no background labeling. The analyte can also be captured with one analyte specific reagent and detected with second antibody specific to the different epitope in sandwich immuno assay based method. The sandwich immuno assay based method is shown in this slide.

(Refer Slide Time: 16:43)

Indirect labeling

- Merits
 - Higher specificity
 - Very sensitive
- Demerits
 - Cross reactivity
 - Multiplexed analysis not possible
 - High cost

Indirect labeling method has various merits. It offers a high sensitivity and specificity, it also has few demerits, for example, use of sandwich assay for multiplex detection is usually limited to few targets like 30 to 40 targets due to lack of specific antibodies for all the purified antigen targets, it often used to cross reactivity. A multiplex analysis is not possible and the high cost is also huge hurdle in utilizing these protocols. We shall move on to rolling circle amplification or RCA method.

(Refer Slide Time: 17:26)

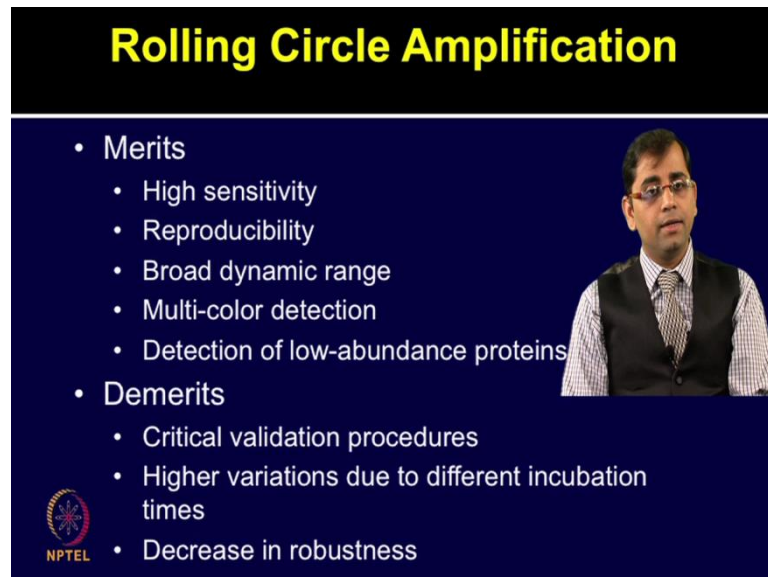

(C) Rolling Circle Amplification

The diagram illustrates the Rolling Circle Amplification (RCA) process. At the bottom, a microarray chip is shown with several red Y-shaped capture antibodies. One antibody is bound to a green 'Biotin' tag. This tag is connected to a 'Streptavidin' molecule, which is in turn bound to a 'Fluorescent tag' (represented by a blue and yellow line). The 'Fluorescent tag' is shown as a long, continuous strand that has been amplified by rolling circle amplification, forming a large loop. The NPTEL logo is visible in the bottom left corner, and a speaker is shown in the bottom right corner.

RCA is very effective method for on chip signal amplification to improve the detection limits in a microarray experiment. In RCA, the capture antibody is printed on the microarray and it binds to the analyte of interest, after that it can be detected by a biotin labeled secondary

antibody, this is then detected by oligonucleotide linked anti-biotin antibody as shown in this slide. The 2 color RCA method has also been used for detection of various labeled proteins from serum sample that are captured on antibody microarrays. RCA method produces 34 higher fluorescence as compared to direct or indirect fluorescence labeling approaches.

(Refer Slide Time: 18:33)

A presentation slide titled "Rolling Circle Amplification" in yellow text on a black background. The slide has a dark blue background with white text. It lists merits and demerits of RCA. On the right side, there is a small inset image of a man with glasses, wearing a white shirt, a patterned tie, and a dark vest. In the bottom left corner, there is a small circular logo with the text "NPTEL" below it.

Rolling Circle Amplification

- Merits
 - High sensitivity
 - Reproducibility
 - Broad dynamic range
 - Multi-color detection
 - Detection of low-abundance proteins
- Demerits
 - Critical validation procedures
 - Higher variations due to different incubation times
 - Decrease in robustness

Advantages of RCA method as compared to direct or indirect fluorescence labeling includes higher sensitivity, reproducibility, broad dynamic range of detection, multicolor detection and detection of low-abundant proteins. The demerits include the critical validation procedures, higher variability due to the inherent incubation timings which are different for these assays.

I will now talk to you about a Generic scheme of fluorescence detection by illustrating the concept in an animation. For protein microarray detection various types of dyes such as fluorescence, (())(19:19) are most commonly used factors which lower the choice of fluorophore depends on sample types substrates, light emission spectrum, various type of characteristics and number of target proteins which one wants to study. So, let me show you this animation for explaining these concepts.

(Refer Slide Time: 20:00)

The array surface is functionalized with probe antibody molecules specific for the target antigen of interest. The target antigens get bound to their primary antibodies on the array surface, detection is carried out by means of fluorescent labeled secondary antibodies. The excess unbound secondary antibody is washed off and the fluorescence measured by exciting the array with light of suitable wavelength. The resulting emission is measured using a microarray scanner and can be used to quantify the corresponding antigen-antibody interaction as shown on the right hand side in the graph, the time versus fluorescence intensity is plotted and one can look at the peak to measure this fluorescence intensity. Sensitivity of less than one nanochrome are achieved by using these fluorescent dyes.

(Refer Slide Time: 21:37)

Points to Ponder:

- Fluorescence is a phenomenon by which a substance absorbs radiation of one wavelength and emits another, usually longer wavelength
- The fluorescent labels are used to tag the probe molecule binding to the analyte of interest on microarray surface
- Three major types of fluorescent labeling methods are:
 1. Direct labeling
 2. Indirect labeling

NPTEL

Points to Ponder:

- Direct labeling involves target protein to be labeled directly with a fluorophore like Cy3 and Cy5
- It allows the co-incubation of reference sample or control sample with an analyte of interest
- It is less sensitive for low abundance proteins and there are instances of cross reactivity due to chemical modification.
- In indirect labelling, detection is through a secondary antibody attached to a fluorophore molecule.

NPTEL

Points to Ponder:

- This is highly sensitive
- In RCA the captured antibody is printed on the microarray and it binds to the analyte of interest which is detected by a biotin-labeled secondary antibody
- This is then detected by oligonucleotide linked anti-biotin antibody and is highly sensitive however require critical validations

NPTEL

So, in today's lecture we have learned about some of the conventional methods of label-based detection system utilized in protein microarrays. In next lecture, we will study some of the novel emerging platforms for detection in interactomics study, Thank you.

(Refer Slide Time: 22:53)

Summary

- Labeling techniques play a crucial role in interactomics
- Protein microarrays have been essentially established on label based detection systems, although label free techniques are now widely emerging
- Some traditional label based detection systems are Chromogenic detection techniques, Chemiluminescence based detection, Radioactivity based detection and Fluorescence based detection
- Each of these techniques have varied sensitivities, merits and de-merits which are scaled by the researcher and used according to the experiment a biologist wishes to study
