Lecture – 08
Solution to PP 2.2

Welcome to lecture number 8, the NPTEL online certification course on Bioreactors. When we finished up the last lecture, we had looked at a problem on enzyme inhibition. Before that in the lecture itself we had looked at three types of inhibitions, the competitive inhibition, the non-competitive inhibition and the uncompetitive inhibition which were different in the way the inhibitor effects the reaction. In the first case, the inhibitor bound to the enzyme, in the second case the inhibitor bound to the enzyme substrate complex and in the third case it bound to both, I think I mixed up the last two but you get the idea, where the inhibitor binds made the difference. Then we looked at a problem which could help us understand this a little better. Let us work out that problem in this lecture.

(Refer Slide Time: 01:17)

Practice problem 2.2

An enzyme normally displays Michaelis-Menten (M-M) behaviour in converting a substrate, S, to a product, P. It gave the following data when its M-M parameters for the above conversion were estimated in the presence of another substance I at different concentrations. Determine the type of inhibition, and the inhibition constant.

M-M parameters/I, mM→	0	0.5	1	5	10
v_{max} , mM min ⁻¹	0.33	0.33	0.33	0.33	0.33
K_m , mM	0.120	0.126	0.132	0.180	0.240

Practice problem 2.2, An enzyme normally displays Michaelis-Menten behavior in converting a substrate, S, to a product, P. It gave the following data when its Michaelis-

Menten parameters for the above conversion were estimated in the presence of another substance I at different concentrations. Determine the type of inhibition and the inhibition constant, the Michaelis-Menten parameters V_m and K_m at different inhibitor concentrations were given in this table. Now, how do we go about it? Let us ask our regular questions.

(Refer Slide Time: 01:55)

What is needed?

- Type of inhibition
- Inhibition constant

What is known/given?

Data on M-M parameters, v_m and K_m at different inhibitor (I) concentrations

What is needed? The type of inhibition and the inhibition constant; k_I . What is known or given, the data on the Michaelis-Menten parameters V_m and K_m at different inhibitor concentrations are given and How to connect what is needed to what is given?

(Refer Slide Time: 02:17)

How to connect what is needed to what is given?

We have seen that v_m and K_m change differently with I , for different types of inhibitions

$v = v_m \frac{S}{K_m \left(1 + \frac{I}{K_I}\right) + S}$	Type of inhibition	V_m changes	K_m changes
$v = \frac{v_m}{\left(1 + \frac{I}{K_I}\right)} \frac{S}{K_m + S}$	Competitive	no	yes
$v = \frac{v_m}{\left(1 + \frac{I}{K_I}\right)} \frac{S}{\left(\frac{K_m}{1 + \frac{I}{K_I}}\right) + S}$	Non-competitive	yes	no
	Un-competitive	yes	yes

We have seen that V_m and K_m change differently with I for different types of inhibitions. For the competitive inhibition, the K_m gets modified.

$$v = \frac{dP}{dt} = v_m \frac{S}{K_m \left(1 + \frac{I}{K_I}\right) + S}$$

For the noncompetitive inhibition, the v_m gets modified and for the uncompetitive inhibition both V_m and K_m got modified in this fashion, this is the summary. The type of inhibition is competitive, noncompetitive, uncompetitive. In the case of competitive inhibition, V_m remains the same there is no change whereas K_m changes. In the case of noncompetitive v_m changes, but K_m does not change and in uncompetitive both V_m and K_m change. So, we need to find out what changes here.

(Refer Slide Time: 03:22)

An inspection of the data tells us that v_m does not change with I , but K_m does.

Thus, this is a case of competitive inhibition

For competitive inhibition,
$$K_m' = K_m \left(1 + \frac{I}{K_I} \right)$$
$$K_m' = \frac{K_m}{K_I} I + K_m \quad y = m x + c$$

When we have a set of data, it is best to use all the relevant ones. If we plot K_m' vs. I , we would get the slope as K_m/K_I . Thus, we can find K_I .

Now, if we look at the data, if we inspect the data, it tells us that V_m does not change with I , but K_m changes. Let me show this to you here. The data was this, as the inhibitor concentration changed, 0, 0.5, 1, 5 and 10, the V_{max} remain the same at 0.33, whereas K_m changed. This is what we saw, what we said earlier and this is what the data shows us.

This is clearly a case of competitive inhibition so that is straight forward. That is the first question, what kind of a competition it is? So, for a competitive inhibition, this K_m' , the new K_m is

$$K_m' = K_m \left(1 + \frac{I}{K_I} \right)$$

$$K_m' = \frac{K_m}{K_I} I + K_m$$

I have written it of a form of $y = mx + c$. Remember we are dealing with a set of data here. Therefore, whenever we deal with data, we need to use the entire set of data. If we just pick points from there, the errors in the data collection would directly get transferred and probably get magnified. If you are using the data point, which happen to be incorrect

then the errors would be large in the estimates.

That is the reason why we need to use the entire set of data whenever we have data to work with and we are trying to use the entire set of data to find, whatever is necessary here which is the inhibition constant. To do that, I am looking at this in a y equals m x plus c form. K_m' is y, I is x and the slope in that case is K_m/K_I and the intercept is K_m . We have data of V_m , K_m with varying I's, so I is the independent x coordinate, K_m' - the modified K_m is the y coordinate. If we plot it that way, then we could get K_m , K_I from here and K_m from the intercept.

This is what we just mentioned, it is good to repeat this. When we have a set of data, it is best to use all the relevant ones. If we plot K_m' versus I, you would get the slope as K_m/K_I and thus we could find K_I .

From a plot of K_m' versus I as this, the equation was $y = 0.012x + 0.12$, y in this case is K_m' , x is I, so

$$K_m' = 0.012 I + 0.12.$$

The intercept $K_m = 0.12$ from the equation

$$\therefore \text{slope } \frac{K_m}{K_I} = 0.012$$

$$\frac{K_m}{0.012} = K_I = \frac{0.12}{0.012} = 10mM = \text{the inhibitor constant}$$
