Lecture – 79
Complex Numbers and Quaternion's

Vanakam, welcome to this video on biomechanics we have been looking at some practical examples practical applications measuring body segment kinematics using various methods. We looked at the rotation matrices we looked at Euler angles and we will continue our discussion of angle axis representation and quaternions in this video.

(Refer Slide Time: 00:48)

So, in this video we will discuss axis angle representations quaternions, how complex numbers and rotations are represented and how to find relative orientation using quaternions.

(Refer Slide Time: 01:08)

Parameterization of rotations - Axis angle representation

- Every 3D rotation corresponds to rotation by an angle about an axis
- The axis of a rotation is the line which is unchanged by rotation

$$R x = \lambda x$$

$$(R - \lambda I) x = 0$$

The angle can be obtained using:

$$1 + 2\cos\theta = \text{trace}(R)$$

Handwritten notes:
 $R = \begin{bmatrix} 1 & 0 & 0 \\ 0 & \cos\theta & -\sin\theta \\ 0 & \sin\theta & \cos\theta \end{bmatrix}$
 $1 + 2\cos\theta = \text{Trace}(R)$
 "θ"
 What is this? NOT an Euler angle.
 θ = ?

Biomechanics

So, every notation in 3D essentially implies rotation about an angle or rotation of or by an angle about an axis. yesterday I gave the example of where this body let us assume that there are three principal axis under discussion for example that axis that axis and that these are the three principle axis. Now let us say this body is undergoing that rotation the axis about which the rotation is happening will have components in this axis this axis and the vertical axis.

And the rotation earlier it was vertical this. Now its horizontal rotation is about 90 degrees the net rotation is about 90 degrees. So, any rotation that happens in 3D essentially is rotation that is happening by an angle about a axis that does not mean that that axis is one of the principal axis and the angle is one of the Euler angles here I am talking about the net rotation that is happening the total rotation is happening about an axis and the angle that it rotates about is the net rotation.

For example I can represent this rotation as a combination of multiple rotations as a combination of three rotations in the three axis. The question is how do I find the axis of rotation? Well that is the particular vector that is the particular line that does not change due to rotation right. For example if this object is undergoing that rotation right. Let us Mark a point here that will undergo a change due to the rotation.

But the axis the set of all points on the axis of rotation will not undergo any change due to rotation. So, suppose R is the rotation Matrix. So, I can perform an eigen value decomposition and represent this as $R x = \lambda x$. So, the characteristic equation then is

$R - \lambda I$ times x is 0. And the question is what is this x it turns out that the rotation Matrix R will have an eigen value 1.

Now eigenvector that corresponds to eigen value + One is the axis about which the rotation is happening will take some simple examples and check if this is indeed true. Now the question is what about the angle of rotation how much or by how much the rotation has happened? Well that you can find by using this relationship $1 + 2 \cos \beta$ is Trace of R . From this find the value of β that is not really too difficult to find.

So, if you have the rotation Matrix find the trace of that Matrix the trace of that Matrix is $1 + 2 \cos \beta$ and find the value of β from this relationship that is the relationship between the angle of rotation and the rotation Matrix. Remember what is this β is it the rotation about the x axis or y axis or the z axis. Remember this β is not an Euler angle this is not an Euler angle this is the net angle of rotation.

This is a net angle of rotation. Now let us check if this is true for the simple case when the rotation is happening about the x axis by an angle θ . So, what would be the rotation Matrix we know what the rotation Matrix is from the previous class that would be $\begin{pmatrix} 1 & 0 & 0 \\ 0 & \cos \theta & -\sin \theta \\ 0 & \sin \theta & \cos \theta \end{pmatrix}$ this is the rotation Matrix R right. In this case what is the trace of this Matrix.

The trace of this Matrix is the sum of these three elements is it not that is $1 + 2 \cos \theta$ equal to the trace of the Matrix R is it not. Now it is very clear that the rotation angle is the rotation angle is θ how do we know this? Just compute this and you will know that this rotation angle is θ because you just have to take the you just have to look at the rotation Matrix and it is immediately obvious that this is a rotation that is happening about the x axis and the angle of rotation is θ right.

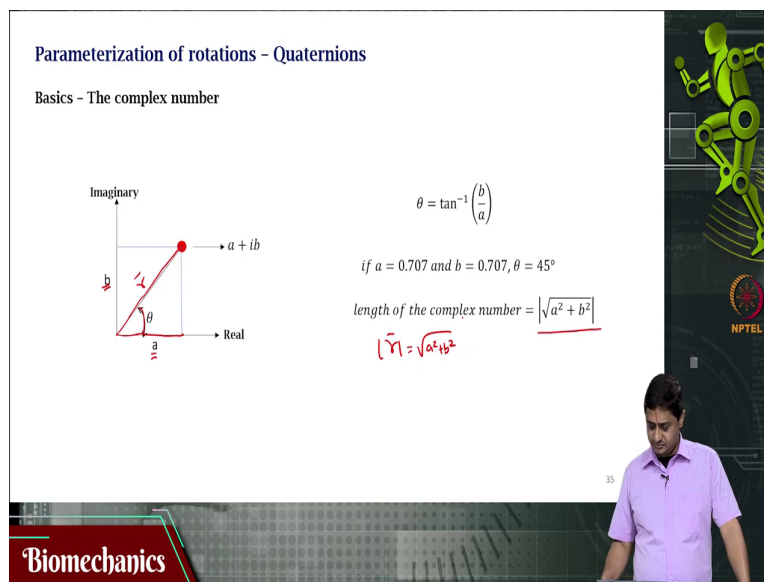

Now of course this is the simple case of the rotation happening about one of the three principal axis right this is the case when the rotation is happening about the x axis. But the question is what would this be when the rotation is a composite rotation. That is the rotation has components in all the three directions in all the or about all the three axis there is a component of rotation that has happened.

Now what is the angle of rotation? Remember once again this angle of rotation that we are discussing for a composite rotation Matrix is the net rotation you cannot compute the Euler angles from this. This is not an Euler angle but the net rotation that has happened for example I gave the example of this phone being rotated right. So, this is the phone and I am rotating it. Now, because the three axes have different components for this rotation or for the axis of rotation.

The net rotation might be some angle say 80 degrees or 90 degrees in this case but the Euler angles for each of the three are the Euler angles about each of the three axes will not be that value. So, you cannot find the Euler angles by looking at the net rotation. Here what we are looking at is the net rotation and the axis of rotation this axis of rotation may have components about the three principle axis something to keep in mind that there is a fundamental difference between this axis and this angle and the Euler angle.

So, right and the principal access so, this is a simple concept that you can use to find the actual axis about which the rotation is happening and the angle of the net angle of rotation something to remember and keep in mind.

(Refer Slide Time: 09:48)

The slide is titled "Parameterization of rotations - Quaternions" and has a subtitle "Basics - The complex number". It features a diagram of a complex number $a + ib$ in the complex plane, with the real axis labeled "Real" and the imaginary axis labeled "Imaginary". The point $a + ib$ is marked with a red dot, and a vector from the origin to this point is shown. The angle θ is indicated between the positive real axis and the vector. The components a and b are labeled on the axes. To the right of the diagram, the formula $\theta = \tan^{-1}\left(\frac{b}{a}\right)$ is given. Below this, it states "if $a = 0.707$ and $b = 0.707$, $\theta = 45^\circ$ ". The length of the complex number is given as $\text{length of the complex number} = \sqrt{a^2 + b^2}$, with a handwritten note $|\tilde{\gamma}| = \sqrt{a^2 + b^2}$ in red. The slide also includes a small image of a person in the bottom right corner and a "Biomechanics" logo in the bottom left corner.

Now let us use quaternions let us discuss the concepts of Quaternions and how we can use quaternions to parameterize rotations. Now this is something that we know from high school I have and I have a complex number say $a + ib$. Now this has a component a along the x axis under component b along the y axis. Now I can represent this also as a vector for example

that vector and an angle that rotation it is as if I have taken this Vector along the real axis and rotated it by that angle theta right.

So, let us say I know a and b I know the values a and b how would you find theta from high school mathematics I know that that is actually tan inverse of b by a we know this. Now let us suppose a is 0.7 not seven and b is 0.7 not 7 then theta is 45 degrees the what is the magnitude of this that is the square root of the sum of the squares but not this is the magnitude that is R right. This is also something that we know from high school math.

(Refer Slide Time: 11:48)

Parameterization of rotations - Quaternions
Complex number- Representing rotation in 2D plane

$a + ib$ $c + id$
 $a = 0.707$ and $b = 0.707$, $\theta = 45^\circ$ $c = 0.877$ and $d = 0.5$, $\theta = 30^\circ$

$\text{length} = \sqrt{a^2 + b^2} = 1$ $\text{length} = \sqrt{c^2 + d^2} = 1$

$(a + ib)(c + id) = (ac - bd) + (ad + bc)i$
 $= (0.707 \times 0.877 - 0.707 \times 0.5) + (0.707 \times 0.5 + 0.707 \times 0.877)i$
 $= (0.266539) + (0.973539)i$

$\text{length} = \sqrt{(0.266539)^2 + (0.973539)^2} = 1$

$\theta = \tan^{-1} \left(\frac{0.973539}{0.266539} \right) = 75^\circ$

For complex numbers to represent rotation, their length should always be equal to unity.

Biomechanics

Now let suppose that I have 2 complex numbers $a + ib$ and $c + id$ where a is 0.797 b is 0.707 theta is some 45 degrees c is 0.877 and d is 0.5 and theta is sum 30 degrees. So, that is for this a and b the corresponding theta is 45 degrees that is when a and b are 0.707 the theta is 45 degrees and when c and d are respectively 0.877 and 0.5 theta is 30 degrees right. Now what is the length of these 2 complex numbers are these 2 vectors that is actually one because square root of a square + b squared is one in this case.

Now let us say that I am multiplying these 2 complex numbers $a + ib$ times $c + id$ will give me a another complex number with real part $ac - bd$ and an imaginary part $ad + bc$ I perform this multiplication and I find this is actually the real part is actually 0.266 and the imaginary part is actually 0.97 4 approximately and the length of this multiplied complex number the new complex number that is the product of the 2 original complex numbers is also one.

That is that number in the unit circle that is this number on the unit circle and you realize the theta for these 2 imaginary and real parts turns out to be 75 degrees. What this means is that multiplying these 2 complex numbers essentially implies that I am adding these 2 rotations one after the other first I am doing $a + ib$ then I am doing $c + id$ resulting in this composite in this rotation resulting in this rotation that is the sum of the 2 individual rotations 30 degrees and 45 degrees.

When you sum them the net rotation the total rotation would be 75 degrees for this to happen there is a condition there is a precondition that is the length should always be one only when the length is one you can actually represent or you can use complex numbers to represent rotations something that we need to keep in mind.

(Refer Slide Time: 14:54)

Parameterization of rotations - Quaternions

Complex number- Relative orientation using the conjugate

$a + ib$ $c + id$

$a = 0.707$ and $b = 0.707$, $\theta = 45^\circ$ $c = 0.877$ and $d = 0.5$, $\theta = 30^\circ$

$length = \sqrt{a^2 + b^2} = 1$ $length = \sqrt{c^2 + d^2} = 1$

$conj(c + id)(a + ib) = (c - id)(a + ib) = (ac + bd) + (bc - ad)i$

$= (0.707 \times 0.877 + 0.707 \times 0.5) + (0.707 \times 0.877 - 0.707 \times 0.5)i$

$= (0.973539) + (0.266539)i$

$length = \sqrt{(0.973539)^2 + (0.266539)^2} = 1$

$\theta = \tan^{-1}\left(\frac{0.266539}{0.973539}\right) = 15^\circ$

$(a + ib)(c + id)$ - Similar to addition

$conj(c + id)(a + ib)$ - Similar to subtraction

Biomechanics

Now let us look at how we can use the complex number representation to find relative orientation remember in one of the previous videos we looked at finding the difference or relative orientation between 2 joints as for example something like R_2^T times R_1 something like this right remember. Now what is this R_2 and R_1 these are rotation matrices. The question is, is there an equivalent in the complex number space for this transpose right yes that is there that is the complex conjugate.

Now if I have a complex number $x + iy$ what is its complex conjugate we know that that is actually $x - iy$ that is the complex conjugate. Now if I am interested in finding the relative orientation between these 2 points that is $a + ib$ and $c + id$ where a was a and b where 0.707

and 0.707 respectively that is what we saw in the previous slide that is representing theta as 45 degrees and $c + id$ where c is 0.877 and d is 0.5 representing theta equal to 30 degrees.

Now remember both of these have length one suppose I find the complex conjugate of this I find the complex conjugate of $c + id$ and I multiply it with $a + ib$ here it shows actually as plus that is actually a multiplication. So, this is actually $c - id$ times $a + ib$ that that will actually give you another complex number with real part $ac + bd$ and imaginary Part $bc - ad$ remember that this is different from what we did previously.

Because here I am not multiplying $a + ib$ and $c + id$ rather I am multiplying $c - id$ and $a + ib$ when I do that I will get this complex number and if I find the theta as tan inverse of b by a will get 15 degrees. Now what is this 15 degrees this is the difference between the original the first angle 45 degrees and the second angle 30 degrees remember we performed this R 2 transpose times R 1.

Now the transpose is going to help you find the relative orientation remember. So, if I have $a + ib$ times $c + id$ then that is essentially similar to addition and if I multiply the complex conjugate of $c + id$ with $a + ib$ that is similar to subtraction. Of course this will work only when the magnitude is one or when all of these numbers are on the unit circle otherwise this will not work but this is an interesting formulation.

(Refer Slide Time: 18:43)

Parameterization of rotations - Quaternions

Quaternions- Representing 3D rotations in a 4D hypersphere

$q = [a, b, c, d] \in \mathbb{R}^4$

$a^2 + b^2 + c^2 + d^2 = 1$ represents a hypersphere

$q = a + bi + cj + dk$
 Extension to 3D

Complex number (2D)

a - real part b, c, d are the imaginary part

Handwritten notes: $a+ib$, $c+id$, $\sqrt{a^2+b^2}=1$, $(a+ib)$

Diagram: A 3D sphere with axes i (red), j (green), and k (blue).

Biomechanics

Now similar to what we had $a + ib$, $c + id$ what is this I what does this I represent it just tells you that what follows this I is the imaginary part this is a complex number with an imaginary

part I that is what it tells you right. Now similar to that let us suppose I had a vector $q = a + b\mathbf{i} + c\mathbf{j} + d\mathbf{k}$ like this right such that $a^2 + b^2 + c^2 + d^2 = 1$ remember in the previous discussion we just said that $a^2 + b^2 = 1$ or rather the square root of $a^2 + b^2$ is one but the square root of $a^2 + b^2$ if it is 1 then $a^2 + b^2 = 1$ so, right.

Now this $a^2 + b^2 + c^2 + d^2 = 1$ is such that that it represents a hypersphere in 4D space immediately what we realized is that 4D that is not intuitive that is the issue with quaternions. That the moment the instant you say quaternions they are not immediately intuitive you are not having a feel for this unlike Euler angles for which you have a feel you have an idea of what is going on.

But in quaternion s because this is in 4D hypersphere you do not have an idea or you do not have an intuitive understanding or feel that does not mean that this is not as useful or as critical this is a very useful method but with some difficulty or with a lot of difficulty in getting a intuitive feel for this. So, all these points remember when we represented the complex number we said that is we said that that is the number $a + ib$.

Now this is on the circumference of the unit circle right correct. In this case for a quaternion this will be $a + ib + cj + dk$ each of this will be such that this quaternion will be a point on the surface of this 4D hypersphere like you are having this for the unit circle this is what would happen when you have a 4D hypersphere and all of these coordinates are points on the surface of this hypersphere.

So, in this case a alone is the real part and b, c, d are imaginary parts. So, this is the extension to 3D of this complex number representation.

(Refer Slide Time: 22:08)

Parameterization of rotations - Quaternions

Understanding quaternions through the axis angle representation

$$q = [q_0, q_1, q_2, q_3]$$

$$q = \left[\cos\left(\frac{\theta}{2}\right), V_x \sin\left(\frac{\theta}{2}\right), V_y \sin\left(\frac{\theta}{2}\right), V_z \sin\left(\frac{\theta}{2}\right) \right]$$

$V = [V_x, V_y, V_z]$ represents the axis about which a rotation of θ has occurred

Handwritten notes and diagrams:

- $U_x \sin 45^\circ = 0.707$
 $U_y = 0.707 / 0.707 = 1$
- $U_x \sin \frac{\pi}{2} = 0$
 $U_y \sin \frac{\pi}{2} = 0$
 $U_z \sin \frac{\pi}{2} = 0$
- $Q = [1, 0, 0, 0]$
 $\cos \frac{\theta}{2} = 1$
 $\frac{\theta}{2} = \cos^{-1}(1)$
 $\theta = 0$
 $V_x = 0$
 $V_y = 0$
 $V_z = 0$
- $Q = [0, 1, 0, 0]$
 $\cos \frac{\theta}{2} = 0$
 $\frac{\theta}{2} = \cos^{-1}(0) = \frac{\pi}{2}$
 $\theta = \pi$
- $Q = [0, 0, 1, 0]$
 $\cos \frac{\theta}{2} = 0$
 $\frac{\theta}{2} = \cos^{-1}(0) = \frac{\pi}{2}$
 $\theta = \pi$
- $Q = [0.707, 0.707, 0, 0]$
 $\cos \frac{\theta}{2} = 0.707$
 $\frac{\theta}{2} = \cos^{-1}(0.707)$
 $\theta = 2 \cos^{-1}(0.707)$
 $\theta = 90^\circ$
- $Q = [0.707, 0, 0, 0.707]$

Diagram showing a 3D coordinate system with axes V_x, V_y, V_z and a rotation angle θ around the axis V .

NPTEL logo

Biomechanics

Now in the beginning of this video we started discussing axis and angle representation we said that that I can actually find the net rotation and the axis about which the net rotation is happening remember right this is called axis angle representation angle axis representation depending on how you call it. Now let us suppose I have a quaternion q naught q_1 q_2 q_3 I can represent this as \cos of θ by 2 $V_x \sin \theta$ by 2 $V_y \sin \theta$ by 2 and $V_z \sin \theta$ by 2.

Now in this case it turns out the rotation the angle of rotation is actually θ and the axis about which this rotation has happened is V_x , V_y and V_z this is the axis or these components in x , y and z constitute together constitute the vector about which this rotation has happened or this is the axis about which this rotation has happened similar to what we discussed. Now consider these five sets of quaternions five quaternions that are given.

Find the axis about which the rotation is happening and the angle by which the rotation has happened how do you do this well we just said how to do it. We will start with the first example what it says is $\cos \theta$ by 2 is equal to one what does that say about θ well that says that θ by 2 is \cos inverse of 1 is it not when is this happening this is true only when θ is 0 is it not.

What about V_1 V_2 V_3 well V_1 is 0, V_2 is 0 V_3 is 0. This is a rotation of 0 degrees about none of that that is there is no rotation essential about none of the three axis right because none of the three axis have any representation all of them are 0 0 0s right remember V_x V_y

V_z represents the axis about which the rotation happens that is the last three components right the first one is the angle.

Now let us look at the second $1\ 0\ 1\ 0\ 0\ 0\ 1\ 0\ 0$ what does that say $\cos \theta/2$ is 0. Now that means $\theta/2$ is \cos^{-1} of 0 what is that that is $\pi/2$ is it not that is $\pi/2$ R_{θ} θ is π it is a rotation of 180 degrees. But about which axis to find that I can find out that $V_x \sin \theta/2$ $\sin \pi/2$ is equal to one is it not. Now that will give me the value what is $\sin \pi/2$ $\sin \pi/2$ is 1 is it not.

So, this is the axis also is there any component of rotation that is happening about these axis probably no because $V_y \sin \theta/2$ $\sin \pi/2$ is equal to 0 it says that means although $\sin \pi/2$ is 1 V_y must be 0 for this to be 0 is it not likewise $V_z \sin \theta/2$ $\sin \pi/2$ is equal to 0 how do I know because this is the quotient $0\ 1\ 0\ 0$ is the quotient the third and fourth components are 0's.

So, $V_z \sin \pi/2$ is 0 but $\sin \pi/2$ itself is one that means that V_z must be 0 that is what it says. So, this quaternion $0\ 1\ 0\ 0$ is a rotation by π radians are 180 degrees about the x axis about the x axis right is also called as pitch x axis that is $1\ 0\ 0$ also called pitch or I will write here this is called pitch right. Now let us look at this case of q equal to $0.707\ 0.707\ 0\ 0$ again these numbers are conveniently taken.

So, that it is not too complicated for you the actual problems that you will come across in real life and probably in the exam need not be so, simple ok but let us continue. So, q is $0.707\ 0.707\ 0\ 0$ no $\cos \theta/2$ is 0.707. So, what is $\theta/2$ or other θ is 2 times \cos^{-1} of this value is it not we know what this value is \cos^{-1} of 0.707 is actually 45 degrees 2 times 45 degrees is actually 90 degrees θ is the angle of rotation is 90 degrees.

Now what about this is $V_x \sin \theta/2$ what is θ θ is 90 degrees that is $\sin 45$ or rather $\pi/4$ is equal to 0.707 but we know this value is 0.797 is it not how do you know from high school math right. This will give me V_x as you know 0.797 by $\sin 45$ rather one something like that what this means is that the rotation is purely about the x axis only and the angle of rotation is 90 degrees right.

So, here we have taken and solved 2 three of the quaternions you can try on your own for this and this. So, essentially this quaternion what does it represent in this case the axis angle representation represents a rotation of theta about an axis of this body.

(Refer Slide Time: 30:20)

Parameterization of rotations - Quaternions

Converting quaternion to other formats of parameterization

$$q = [q_0, q_1, q_2, q_3]$$

$$R(q) = \begin{bmatrix} 2(q_0^2 + q_1^2) - 1 & 2(q_1q_2 - q_0q_3) & 2(q_1q_3 + q_0q_2) \\ 2(q_1q_2 - q_0q_3) & 2(q_0^2 + q_2^2) - 1 & 2(q_2q_3 + q_0q_1) \\ 2(q_1q_3 + q_0q_2) & 2(q_2q_3 + q_0q_1) & 2(q_0^2 + q_3^2) - 1 \end{bmatrix} \longrightarrow \text{Euler angles}$$

$$q = [q_0, q_1, q_2, q_3] \longrightarrow \text{Euler angles}$$

eulerd(quaternion, sequence, rotation type)*

```
>> eulerd(quaternion([0.707, 0.707, 0, 0]), 'XYZ', 'frame')
```

ans =
90.0000 0 0

<https://www.mathworks.com/help/robotics/ref/quaternion.eulerd.html?d=1>

Biomechanics

Now how do I convert this quaternion to other formats of parameterization such as rotation Matrix such as Euler angles why do I have to do that do I have to do that the answer is yes we have to do that. But why because as we just. Now discussed there is no intuitive understanding of quaternions I need to have an intuitive understanding. So, to have an intuitive understanding I need to convert it to things that I understand well and those are Euler angles and rotation matrices.

And so, suppose I have this quaternion $q = [q_0, q_1, q_2, q_3]$ I can convert this into the rotation Matrix using this formula using this formulation. I am not performing the derivation showing that this is indeed true but you can check whether this is true this is true this is true. And then I can convert from this rotation Matrix to other angles there is a way to convert directly from quantities to Euler angles by using this function Euler d.

Of course I need to know the sequence of rotation I still need to know the sequence of rotation suppose this was the quaternion remember this is the problem that we solved in the previous slide suppose is it not that is what we solved here that is that problem. So, 0.707 0.707 00 right that is what we solved I am converting that to Euler using the Euler d formula right.

I will get the angle of rotation as 90 degrees as we found previously right of course I am taking some simple examples that are having some 0.s right the real quaternion that you measure are the measured quaternions from IMU's are from your electromagnetic tracking systems will not have such simple numbers and they will not be. So, intuitive you will need to convert this to Euler angles.

Of course for this you need the Matlab function of course this is the Matlab function there are maybe equivalents in other packages or languages.

0 40.0000 0
  
```

- Order of multiplication matters
- Conjugate $[[q_0, q_1, q_2, q_3]] = [q_0, -q_1, -q_2, -q_3]$

Biomechanics

Now like we discussed previously how I can find the relative orientation we just showed an example of how we can find the relative orientation. We said that that you can do by finding the complex conjugate of the second one and then multiplying it with the first complex number something like that right. So, suppose I have 2 quaternions q_1 0 20 0 for example and another quaternion.

Quaternion corresponding to this Euler angle and quaternion corresponding to that Euler angle for example and I am interested in converting that is these 2 angles I am having 60 degrees and I am having 20 degrees and I would like to know the relative angle between these 2. This is the kind of problem that we will encounter in real life most likely this is the problem that we are interested in solving right.

Of course the numbers given are simple 20 and 60 obviously you know that the relative angle between this let us say this is the proximal segment and this is the more distal segment is 40

degrees I know this. So, I try to convert this to quaternions first and then I multiply the 2 if I simply multiply the 2 it is going to add like we did in the complex number case if I simply multiply the 2 quaternions using quad multiply of these 2 quaternion q_1 and q_2 .

I am going to simply get the sum of the 2 angles but I am interested in finding the relative orientation to do that what we said in the unit circle case is you find the complex conjugate of the quaternion and then multiply right. If you do that if you do the quaternion multiplication by finding the complex conjugate of one of them and then multiply it with the other you will get the angle as 40 degrees.

Of course the order of multiplication matters right also remember that the like you have if I have a complex number $x + iy$. Let us its complex conjugate is $x - iy$. Now for the quaternion $q_0 + q_1 i + q_2 j + q_3 k$ the complex conjugate is $q_0 - q_1 i - q_2 j - q_3 k$ why because the only real part in that is q_0 q_1 q_2 q_3 are all imaginary parts right. So, if I use complex conjugates and multiply using quad multiply I will find the relative orientation between 2 segments right.

Now let us suppose that I use one IMU to find one quaternion that measures the orientation of this segment and another IMU that measures the orientation of the first segment both of them are outputting in quaternions if I want to find the relative orientation I you know find the complex conjugate and then multiply I will get the relative orientation this is that simple.

(Refer Slide Time: 36:31)

Summary....

- Axis angle representations
- Quaternions
- Complex numbers and rotation
- Relative orientation using quaternions

Biomechanics

NPTEL

So, in this video we looked at axis angle representation we looked at how we can find the axis of rotation and angle of rotation from a rotation Matrix. That is the axis about which a composite rotation happens and the angle by which this composite rotation happens this is the net angle right that we looked at for the rotation Matrix case. Then we introduced the idea of quaternions give some simple examples of complex numbers and rotations and how to find relative orientation between complex numbers right.

And then we introduce the idea of quaternions and axis angle representation for a quaternion. And then we used quaternion principles to discuss relative orientation between 2 segments using quaternions right essentially to First find the complex conjugate of the quaternion and then multiply using quaternion multiply for example in Matlab right. So, with this we come to the end of this video thank you very much for your attention.
