Non-dimensionalization: Thiele Modulus

In the last lecture we derived the mole balance for internal diffusion with surface reaction simultaneously happening. We will build up on that today and solve the equation. And we will look at how the concentration profile actually is a function of the position and what insights we can derive from the concentration profile.

(Refer Slide Time: 01:03)

So, if we take a catalyst pellet, where we have species A which is diffusing from bulk; if the concentration of the species at the surface is $C_{A S}$ and there is internal diffusion that is happening of the species. We derived the mole balance in the last class, where we said that the mole balance is $d^2 C_A / dr^2 + 2/r \cdot dC_A / dr - k_n / D_e \cdot C_A^n = 0$ for a n th order reaction; where k_n takes care of the surface area which is available for the reaction, density of catalyst, so on and so forth.

And the boundary conditions being $C_A = C_{A S}$ @ $r = R$; where R is the radius of the pellet that we considered. And C_A is finite @ $r = 0$. So, what we will do now is, we will solve this equation and then we will find out what is C_A versus r and what kind of insights we can get about the diffusion process by looking at the profile of concentration vs position inside the pellet.

So, as a first step what we will do is, we will actually non-dimensionalize the model equation. And it is often useful to actually non-dimensionalize the equation so that the solution and the insights we get can actually be independent of the size of the pellet that we consider. So, let us first non-dimensionalize the equation and it also helps in solving the model equation.

(Refer Slide Time: 02:53)

Non-dimensionalization

$$\psi = \frac{C_A(r)}{C_{AS}} \quad 0 \leq \psi \leq 1$$

$$\lambda = \frac{r}{R} \quad 0 \leq \lambda \leq 1$$

C_A is finite $\Rightarrow \psi$ is finite
@
 $r=0$
or
 $r=R$

i) $C_A = C_{AS}$ @ $r = R$
 $\Rightarrow \psi = \frac{C_A}{C_{AS}} = 1$ @ $\lambda = \frac{r}{R} = 1$
 $\psi = 1$ @ $\lambda = 1$

Let us assume that psi is C_A which is the local concentration at any position r , divided by the surface concentration C_{AS} . So, what will be the range for this value psi? Because C_{AS} is the concentration of the species that comes from the surface into the catalyst pellet; therefore, the maximum possible concentration anywhere inside the pellet can at best be the surface concentration itself. So therefore, psi is essentially going to be between 0 and 1.

So clearly, psi can, is always in the range of between 0 and 1. 0 when the concentration is 0 at any location, when, 1 when the concentration is equal to that of the surface concentration. Let us also define the, a non-dimensional quantity for position, because the model equation has both concentration and position. Let us define this as r by capital R . What will be the range for the lambda which is the dimensionless position?

Once again clearly lambda is always between 0 and 1. So, let us first look at the boundary conditions in this non-dimensional form. So, the first boundary condition is $C_A = C_{AS}$ @ $r = R$. So, this means that in the non-dimensional form, will see that $\psi = C_A$ by C_{AS} , which should be = 1 @ $\lambda = r$ by $R = 1$. So, the boundary condition is that $\psi = 1$ @ $\lambda = 1$. This is the boundary condition, one of the boundary conditions in the non-dimensional variables that we have just defined.

And what will be the second boundary condition? The second boundary condition will essentially be ψ is finite @ $r = 0$ or $\lambda = 0$. So, concentration C_A is finite, which implies that ψ is finite @ $r = 0$ or λ which is the dimensionless position, that = 0. Now, let us look at the model equations. Let us try to find the dimensionless form of the model equation.

(Refer Slide Time: 05:42)

Dimensionless form of the model equation

$$\frac{d^2 C_A}{dr^2}; \frac{dC_A}{dr}$$

$$\frac{dC_A}{dr} = \frac{dC_A}{d\lambda} \cdot \frac{d\lambda}{dr}$$

So, the model equation has the second derivative of concentration with position. It has first derivative of concentration with position. So, let us try to find out what is the first derivative dC_A by dr , in terms of the dimensionless quantities. Now, simply by chain rule, we can write this as dC_A by $d\lambda$ into $d\lambda$ by dr .

(Refer Slide Time: 06:32)

$$\frac{dC_A}{dr} = \frac{dC_A}{d\lambda} \cdot \frac{d\lambda}{dr}$$

$$\gamma = \frac{C_A}{C_{As}}$$

$$\Rightarrow \frac{dC_A}{d\lambda} = C_{As} \frac{d\gamma}{d\lambda}$$

$$\lambda = \frac{\gamma}{R} \Rightarrow \frac{d\lambda}{dr} = \frac{1}{R}$$

And from here we can rewrite this as, by $d r$ is essentially $= d \psi$ by $d \lambda$, multiplied by $d C A$ by $d \psi$ into $d \lambda$ by $d r$. Now, we know that ψ is $= C A$ by $C A S$. So, from here $d C A$ by $d \psi$ is essentially $= C A S$. And we know that λ is $= r$ by capital R . So, from here, $d \lambda$ by $d r$ is essentially $= 1$ by R . So, substituting these, we will find that $d C A$ by $d r$ is $= 1$ by r into $C A S$ into $d \psi$ by $d \lambda$. Okay. So, that is $= C A S$ by R into $d \psi$ by $d \lambda$. So now, if we now look at the dimensionless form for the second derivative or second derivative in the new variables;

(Refer Slide Time: 07:59)

$$\begin{aligned} \frac{d^2 C_A}{dr^2} &= \frac{d}{dr} \left(\frac{dC_A}{dr} \right) \\ &= \frac{d}{dr} \left(\frac{C_{AS}}{R} \frac{d\psi}{d\lambda} \right) \\ &= \frac{d}{d\lambda} \left(\frac{C_{AS}}{R} \frac{d\psi}{d\lambda} \right) \cdot \frac{d\lambda}{dr} \\ &= \frac{C_{AS}}{R^2} \frac{d^2 \psi}{d\lambda^2} \end{aligned}$$

$d^2 C_A$ by $d r^2$. That is nothing but d by $d r$ into $d C_A$ by $d r$. But we just found out what is $d C_A$ by $d r$. So, that should be $= d$ by $d r$ into $C A S$ by r into $d \psi$ by $d \lambda$. And this we can write by chain rule as d by $d \lambda$ into $C A S$ by r , $d \psi$ by $d \lambda$ into $d \lambda$ by $d r$, which is $= C A S$ by R^2 into $d^2 \psi$ by $d \lambda^2$. So, now we can plug in the first derivative and second derivative in terms of the new variables.

Whatever new variables we have just defined, that we can substitute into the model equation and we can find out the model equation in the new variables. So, what is the model equation?

(Refer Slide Time: 09:07)

The image shows a hand pointing to a whiteboard with four equations written in different colors:

$$\frac{d^2 C_A}{dr^2} + \frac{2}{r} \frac{dC_A}{dr} - \frac{k_n C_A^n}{D_e} = 0$$

$$\frac{C_{A_s}}{R^2} \frac{d^2 C_A}{d\lambda^2} + \frac{2}{\lambda R} \frac{C_{A_s}}{R} \frac{dC_A}{d\lambda} - \frac{k_n C_A^n}{D_e} = 0$$

$$\frac{d^2 \psi}{d\lambda^2} + \frac{2}{\lambda} \frac{d\psi}{d\lambda} - \frac{k_n R^2}{D_e C_{A_s}} C_{A_s}^n \psi^n = 0$$

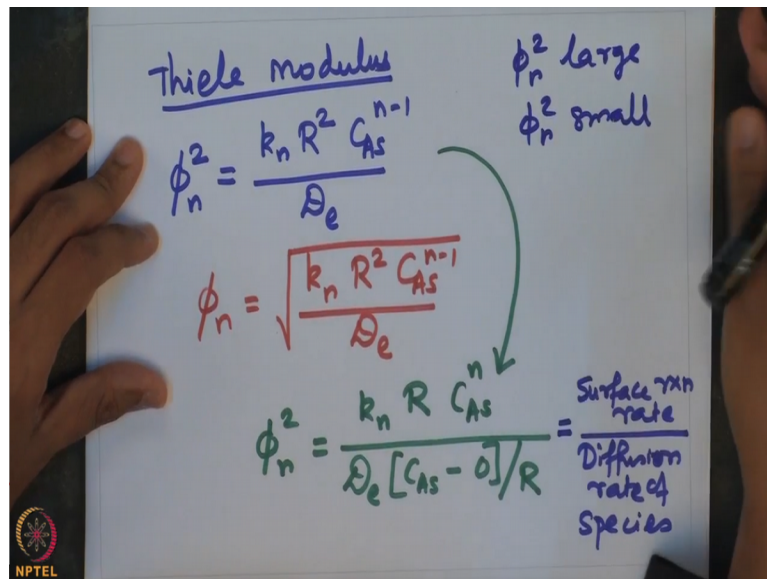

$$\Rightarrow \frac{d^2 \psi}{d\lambda^2} + \frac{2}{\lambda} \frac{d\psi}{d\lambda} - \frac{k_n R^2}{D_e} C_{A_s}^{n-1} \psi^n = 0$$

The model equation is $\frac{d^2 C_A}{dr^2} + \frac{2}{r} \frac{dC_A}{dr} - \frac{k_n C_A^n}{D_e} = 0$. So, we know that $\frac{d^2 C_A}{dr^2}$ is nothing but $\frac{C_{A_s}}{R^2} \frac{d^2 C_A}{d\lambda^2}$. We have $\frac{2}{r}$, we can write r in terms of λ , which is $r = \lambda R$. And that multiplied by $\frac{C_{A_s}}{R}$ into $\frac{d\psi}{d\lambda}$. This should be $\frac{2 C_{A_s}}{\lambda R} \frac{d\psi}{d\lambda}$. $\frac{k_n C_A^n}{D_e}$ into $\frac{k_n R^2}{D_e} C_{A_s}^n \psi^n = 0$. That divided by D_e .

So therefore, so we can rewrite this expression as, $\frac{d^2 \psi}{d\lambda^2} + \frac{2}{\lambda} \frac{d\psi}{d\lambda} - \frac{k_n R^2}{D_e} C_{A_s}^n \psi^n = 0$. And we can also now write C_A^n in terms of the new variable. So, that will be $C_{A_s}^n$ to the power of n into ψ^n to the power of $n = 0$. So, this we can rewrite as $\frac{d^2 \psi}{d\lambda^2} + \frac{2}{\lambda} \frac{d\psi}{d\lambda} - \frac{k_n R^2}{D_e} C_{A_s}^{n-1} \psi^n = 0$.

So, this is the model equation in the dimensionless form which incorporates the dimensionless quantities we just defined. So now, if you stare at this expression here in the model equation, the dimensionless form where we have $\frac{k_n R^2}{D_e} C_{A_s}^{n-1}$ to the power of $n - 1$. So now, let us see what this coefficient actually means. So, the coefficient in front of ψ in term, which is the rate term here is essentially called as the Thiele modulus, square of the Thiele modulus.

(Refer Slide Time: 11:58)

So, we can define ϕ_n square as $k_n R^2 C_{As}^{n-1}$ divided by D_e . So now, this expression here is what is called, is famously called as the square of the thiele modulus, where the thiele modulus ϕ_n is given by square root of $k_n R^2 C_{As}^{n-1}$ divided by D_e . So, if we stare at this expression here, what we see is that in the numerator we have the rate constant or which signifies the rate at which the reaction happens and at the denominator we have effective diffusivity.

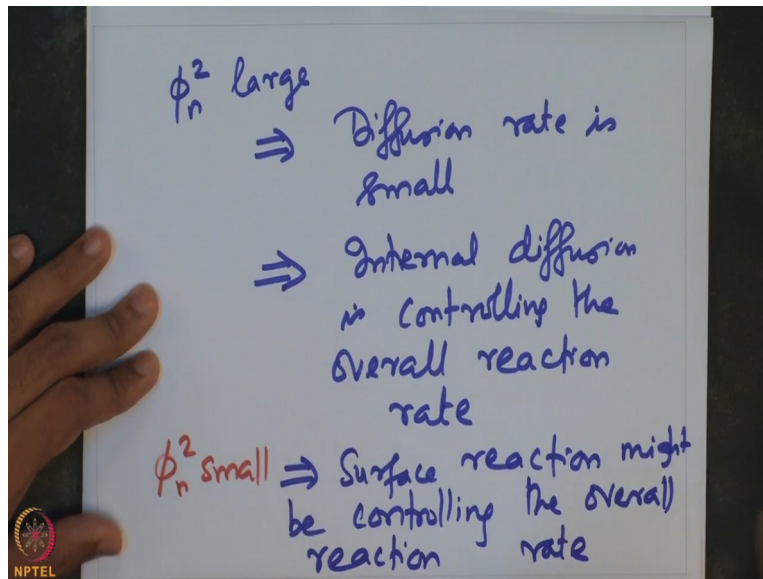

So now, we can, we usually use this notation of ϕ_n , because we use ϕ typically for porosity. So, we use ϕ_n to actually refer to thiele modulus for catalytic systems. We can now rewrite the ϕ_n square expression here in a slightly different manner. We can write it, rewrite this expression as, ϕ_n square is $= k_n R C_{As}^n$ divided by $D_e [C_{As} - 0]$ divided by R .

So, this quantity here in the numerator, this quantity in the numerator refers to the surface reaction rate and the quantity in the denominator actually refers to the diffusion rate of the species. So, one can actually look at thiele modulus as a ratio of the surface reaction rate to the diffusion rate of the species. Now, what happens if ϕ_n square is very large? So, if ϕ_n square is very large, it means that the diffusion of the species is very small.

So, if diffusion of species is very small, then one can actually think of the possibility that the overall reaction rate is essentially controlled by the diffusion of the species or diffusion rate may be the slowest step in the whole process. So now, let us consider the 2 cases where ϕ_n

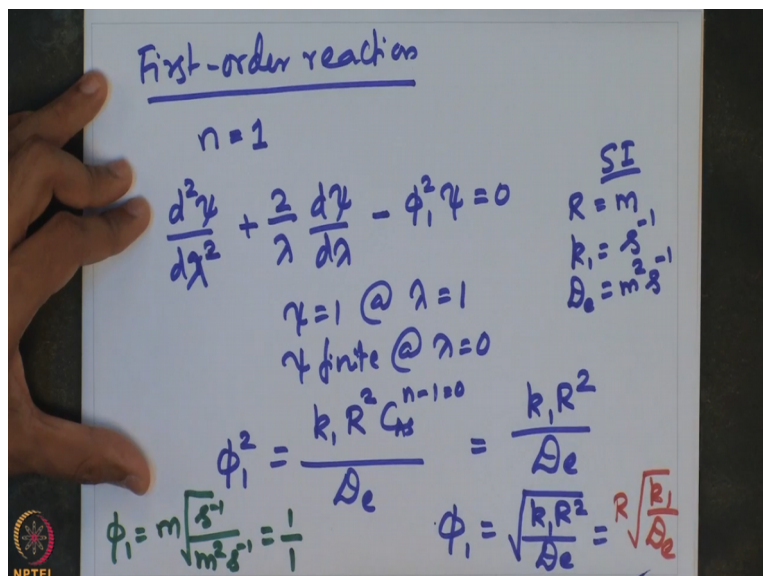

square is, ϕ_n square is large and ϕ_n square is actually small. So, if ϕ_n square is large, then it means that the diffusion rate of the species is very very small.

(Refer Slide Time: 15:18)

And therefore, if ϕ_n square is large, it means that the diffusion rate is small; which implies that the internal diffusion is controlling the overall reaction rate. Suppose if ϕ_n square is small, then it means that the surface reaction might be controlling the overall rate. So, if one knows what is the thiele modulus for a given system that we are looking at, given catalytic reaction and the reaction that is happening, then based on thiele modulus, value of thiele modulus, one can actually find out whether the reaction is likely to be internal diffusion controlled or it is likely to be the surface reaction control. Suppose we take a first order case, first order reaction case, let us consider the;

(Refer Slide Time: 17:01)

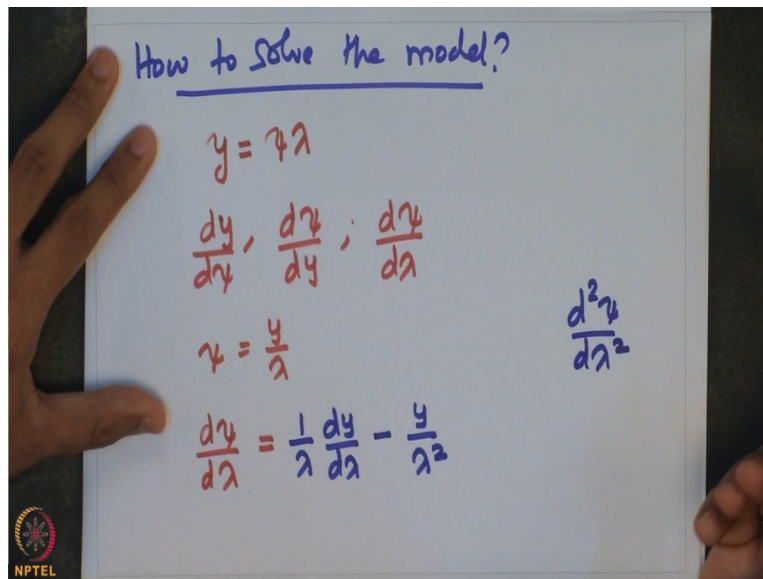

Suppose, let us consider first order reaction here. Where now, order of the reaction n is essentially $= 1$. And the model equation in the dimensionless form is essentially $d^2 \psi / dr^2 + 2/r \cdot d\psi/dr - \phi^2 \psi = 0$. And the boundary conditions are essentially $\psi = 1$ @ $r = 1$. And ψ is finite @ $r = 0$. So, what will be the expression for ϕ^2 ?

So, ϕ^2 will be k_1 , which is the rate constant for the first order reaction, multiplied by R^2 into $C_A S$ to the power of $n - 1$, but n is 1. So therefore, $C_A S$ to the power of $n - 1$, that is essentially $= 0$, divided by the effective diffusivity which is essentially $= k_1 R^2 / D_e$. So now, Thiele modulus now is essentially square root of this expression. So, ϕ is essentially $= k_1 R^2 / D_e$, which can be read, so I can now pull out r from here.

So, that is R into square root of k_1 / D_e . So, what are the units of ϕ ? So, let us look at the units of ϕ . Units of R is, let us say meter. If I use SI units. Units of R is meter. What will be the units of rate constant k_1 for a first order reaction? It is second inverse. And what are the units of effective diffusivity? Is metre square second inverse. So, if I now substitute this into the expression for Thiele modulus, I can see that the units of ϕ is, radius is given by metre and square root of the units for rate constant is second $- 1$.

And the units for diffusivity is metre square second $- 1$. So essentially you will see that the dimensions of Thiele modulus is actually no dimension. It is a dimensionless quantity. So, it is a dimensionless quantity which actually looks at the ratio of surface reaction to the diffusion rate or it actually captures the relative effects of surface reaction and the surface reaction rate and the diffusion rate. It is a quantitative number which helps in identifying whether the surface reaction rate is dominating or the diffusion rate is actually dominating.

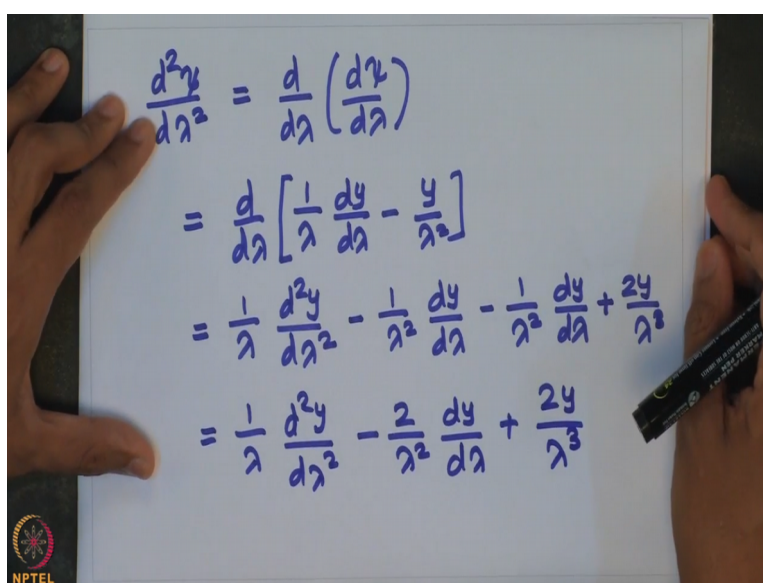

(Refer Slide Time: 20:01)

So, how to solve this equation? So, how do we solve this model? So, in order to solve the model, we need to make a simple substitution. So, let us introduce a substitution where we define a quantity called y , which is essentially $= \psi$ times λ . So, from here, we can see that $d y$; we can find out $d y$ by $d \psi$. We can also, of course we can find out $d \psi$ by $d y$. We, but what we require is actually $d \psi$ by $d \lambda$.

So, how do we find $d \psi$ by $d \lambda$. So, let us rewrite this expression as, ψ is $= y$ by λ . And so now, $d \psi$ by $d \lambda$ is essentially given by 1 by λ into $d y$ by $d \lambda$ $- y$ by λ square. What is next? We need to find out what is $d^2 \psi$ by $d \lambda$ square. So, let us find out what that is.

(Refer Slide Time: 21:22)

So, $\frac{d^2 \psi}{d\lambda^2}$ by $\frac{d\psi}{d\lambda}$ is essentially given by, $\frac{d}{d\lambda}$ of $\frac{\psi}{\lambda}$. And that is $= \frac{d}{d\lambda} \left(\frac{\psi}{\lambda} \right)$; We already know what is $\frac{d\psi}{d\lambda}$. We just found out what is $\frac{d}{d\lambda} \left(\frac{\psi}{\lambda} \right)$. So, we substitute that here. So, that will be $\frac{1}{\lambda} \frac{d\psi}{d\lambda} - \frac{\psi}{\lambda^2}$. That is $= \frac{1}{\lambda} \frac{d\psi}{d\lambda} - \frac{\psi}{\lambda^2}$. So, we substitute that into $\frac{d^2 \psi}{d\lambda^2} + \frac{2}{\lambda} \frac{d\psi}{d\lambda} - \phi_1^2 \psi = 0$.

So now, we can, so this is $= \frac{1}{\lambda} \frac{d\psi}{d\lambda} - \frac{\psi}{\lambda^2}$, $\frac{d^2 \psi}{d\lambda^2} + \frac{2}{\lambda} \frac{d\psi}{d\lambda} - \phi_1^2 \psi = 0$. So, we know what is the second derivative. We also know what is the first derivative. And we can now substitute that into the model equation. Let us do that. So, what is the model equation.

(Refer Slide Time: 22:59)

The image shows a whiteboard with handwritten mathematical steps. The first line is the original equation: $\frac{d^2 \psi}{d\lambda^2} + \frac{2}{\lambda} \frac{d\psi}{d\lambda} - \phi_1^2 \psi = 0$. The second line shows the substitution of the first derivative term: $\frac{1}{\lambda} \frac{d^2 \psi}{d\lambda^2} - \frac{2}{\lambda^2} \frac{d\psi}{d\lambda} + \frac{2\psi}{\lambda^3}$. The third line shows the cancellation of terms: $+\frac{2}{\lambda} \left[\frac{1}{\lambda} \frac{d\psi}{d\lambda} - \frac{\psi}{\lambda^2} \right] - \phi_1^2 \frac{\psi}{\lambda} = 0$. The fourth line shows the simplified equation: $\frac{1}{\lambda} \frac{d^2 \psi}{d\lambda^2} - \phi_1^2 \frac{\psi}{\lambda} = 0$. The final line shows the boxed result: $\Rightarrow \frac{d^2 \psi}{d\lambda^2} - \phi_1^2 \psi = 0$. There is an NPTEL logo in the bottom left corner of the whiteboard image.

The model equation is $\frac{d^2 \psi}{d\lambda^2} + \frac{2}{\lambda} \frac{d\psi}{d\lambda} - \phi_1^2 \psi = 0$. So, from this expression, we can substitute $\frac{d^2 \psi}{d\lambda^2}$ by $\frac{d}{d\lambda} \left(\frac{d\psi}{d\lambda} \right)$. And so, that is essentially $= \frac{1}{\lambda} \frac{d\psi}{d\lambda} - \frac{\psi}{\lambda^2}$. So, we substitute that into $\frac{d^2 \psi}{d\lambda^2} + \frac{2}{\lambda} \frac{d\psi}{d\lambda} - \phi_1^2 \psi = 0$. And now we need to substitute for the first derivative.

So that will be $\frac{2}{\lambda} \left(\frac{1}{\lambda} \frac{d\psi}{d\lambda} - \frac{\psi}{\lambda^2} \right)$ into $\frac{d^2 \psi}{d\lambda^2} + \frac{2}{\lambda} \frac{d\psi}{d\lambda} - \phi_1^2 \psi = 0$. So, from here, we can see that this term cancels out this term. And this term cancels out with this term. And so essentially the model equation is $\frac{d^2 \psi}{d\lambda^2} - \phi_1^2 \psi = 0$.

Which essentially means that the model equation is reduced to $d^2 y$ by $d \lambda^2 - \phi^2 y = 0$. So, what we have seen in today's lecture is we started from the model equation that we derived in the previous lecture. And then we non-dimensionalized the equation. We found out what is the Thiele modulus, the dimensionless quantity which characterises the ratio of or captures the ratio of surface reaction rate to diffusion rate.

And then we introduced the transformation of $y = \psi \lambda$ which is required to solve the model that we are looking at. In the next lecture we will actually solve the model. And we will see what the profile of concentration with respect to position and what is the kind of insights that we can obtain from the solution of the model equation. Thank you.
