Lecture - 11
The non-linear pendulum (continued.)

We were looking at the non-linear pendulum, we had written down the equation of motion for the pendulum.

(Refer Slide Time: 00:20)

Non-Linear Pendulum

$s = l\theta$

$m \frac{d^2 s}{dt^2} = -mg \sin \theta$

$\Rightarrow m l \frac{d^2 \theta}{dt^2} + mg \sin \theta = 0$ (NL eqⁿ)

I.C. $\theta(0) = \theta_0$
 $\dot{\theta}(0) = 0$

$\Rightarrow \frac{d^2 \theta}{dt^2} + \left(\frac{g}{l}\right) \sin \theta = 0$

Non-linear in θ
 (Normal modes will not work)

Small angle approx: $\theta_0 \ll 1$

$\theta(t) = a e^{i\omega t}$

$\sin \theta \sim \theta$

$\frac{d^2 \theta}{dt^2} + \left(\frac{g}{l}\right) \theta = 0$ (Linear Const. Coeff. O.d.e)

$\omega_0^2 = \frac{g}{l}$

It was found to be $d^2 \theta / dt^2 + g/l \sin \theta = 0$. We wanted to solve this equation subject to the initial conditions that I give the pendulum an initial angular displacement and 0 angular velocity.

So, $\theta(0)$ is θ_0 and $\dot{\theta}(0)$ is 0. Now the first thing that we noticed already was that the normal mode approximation will not be appropriate, because this is a non-linear equation. So, if you substitute θ is equal to some number a into $e^{i\omega t}$, this non-linear equation we will not be able to satisfy this and do it the way we did it in the case of linear equations.

Now, we also discussed that this equation is typically solved in the small angle approximation where $\sin \theta$ is approximated as θ , this is typically expected to be valid when the initial displacement θ_0 is small. So, when θ_0 is sufficiently small, then you can expand $\sin \theta$ and replace it by this first term in the Taylor approximation as θ .

And then the resultant equation becomes a linear equation in θ ; this equation is amenable to normal mode analysis, here the equilibrium state is 1 where the pendulum is horizontal. So, that is the base state. So, when we write θ is equal to $a e^{i\omega t}$ on the linearized equation it works.

And leads to a frequency relation which tells us that ω_0^2 is equal to g/l . Once again like before the amplitude a has to be determined from initial conditions and it is in general a complex number. Now, before we go further discuss our solution of the non-linear pendulum in terms of elliptic functions, notice that the frequency of the linearized pendulum is purely a function of the system parameters.

The acceleration due to gravity and the length of the pendulum l , the length of the string which we have assumed to be inextensible here. In particular notice that ω_0 , the natural frequency is independent of θ_0 that the angular displacement with which we leave the pendulum at time t equal to 0.

Let us look at the solution to the exact problem without doing this linearization and let us learn about the features of the non-linear problem.

(Refer Slide Time: 02:34)

Energy of the pendulum (at any time t) is:

$$\left. \begin{aligned} \frac{1}{2} m \left(\frac{ds}{dt} \right)^2 + mgl(1 - \cos \theta) &= mgl(1 - \cos \theta_0) \\ \Rightarrow \frac{1}{2} m l^2 \left(\frac{d\theta}{dt} \right)^2 + mgl(1 - \cos \theta) &= mgl(1 - \cos \theta_0) \\ \Rightarrow \frac{1}{2} \left(\frac{d\theta}{dt} \right)^2 &= \left(\frac{g}{l} \right) [\cos \theta - \cos \theta_0] \quad \leftarrow \\ \Rightarrow \left(\frac{d\theta}{dt} \right)^2 &= 2 \omega_0^2 [\cos \theta - \cos \theta_0] \quad \omega_0^2 \equiv g/l \\ \Rightarrow \left(\frac{d\theta}{dt} \right)^2 &= 2 \omega_0^2 [1 - 2 \sin^2(\theta/2) - 1 + 2 \sin^2(\theta_0/2)] \\ \Rightarrow \left(\frac{d\theta}{dt} \right)^2 &= 4 \omega_0^2 [\sin^2(\theta_0/2) - \sin^2(\theta/2)] \quad \leftarrow \end{aligned} \right\}$$

So, we started by looking at the energy of the pendulum and we wrote an equation of this form, we equated instantaneous energy to the initial energy, in this case the initial energy is purely potential energy.

And it finally led us after some algebraic manipulations, it led us to an equation which was of this form. Notice that this is already a first order equation and that is because we did not start with the equation of motion, but we started with the first integral which is the energy. Now let us continue further.

(Refer Slide Time: 03:08)

$$\left(\frac{d\theta}{dt}\right) = \pm 2\omega_0 \left[\sin^2\left(\frac{\theta}{2}\right) - \sin^2\left(\frac{\theta_0}{2}\right) \right]^{1/2}$$

$$\Rightarrow \pm 2\omega_0 dt = \frac{d\theta}{\left[\sin^2\left(\frac{\theta}{2}\right) - \sin^2\left(\frac{\theta_0}{2}\right) \right]^{1/2}}$$

$\sin\left(\frac{\theta}{2}\right) \equiv z, \quad \sin\left(\frac{\theta_0}{2}\right) \equiv k \quad 0 \leq k^2 \leq 1$
 $\frac{\theta}{2} = \sin^{-1}(z)$
 $\frac{1}{2} d\theta = \frac{dz}{\sqrt{1-z^2}}$

$\left. \begin{aligned} \theta(0) &= \theta_0 \\ \dot{\theta}(0) &= 0 \\ z(0) &= \sin\left(\frac{\theta_0}{2}\right) \\ \dot{z}(0) &= 0 \end{aligned} \right\} \quad \left. \begin{aligned} \xi(0) &= 1 \\ \dot{\xi}(0) &= 0 \end{aligned} \right\}$

$\left. \begin{aligned} \theta \\ z \end{aligned} \right\} \rightarrow \xi$
 $\frac{z}{k} \equiv \xi$
 $dz = k d\xi$

$$\pm \omega_0 dt = \frac{\cancel{k} dz}{\sqrt{1-z^2} \sqrt{k^2 - z^2}} = \frac{dz}{k \sqrt{1-z^2} \sqrt{1-(z/k)^2}}$$

$$= \frac{\cancel{k} d\xi}{\sqrt{1-k^2\xi^2} \sqrt{1-\xi^2}}$$

So, we found that $d\theta$ by dt is equal to plus minus $2\omega_0$ naught $\sin^2 \theta$ naught by 2 minus $\sin^2 \theta$ by 2 to the power half. Now, our next task will be to integrate this equation and I will show you that we can using a simple set of manipulations, we can convert this into elliptic integrals.

Once we convert this into an elliptic integral, we have already discussed the elliptic integral which can be expressed in terms of the inverse of the elliptic functions and so, that will allow us to express θ as a function of time. So, let us continue. So, I will write this as plus minus $2\omega_0$ naught dt is equal to.

This is just a simple algebraic rearrangement and then let us substitute $\sin \theta$ by 2 to be equal to z $\sin \theta$ naught by 2 equal to K . So, you can see that this is the same K that we had

introduced earlier in the case of elliptic functions this was a measure of the shape of the ellipse.

So, K^2 was between 0 and 1; you can see that if you are defined K as $\sin \theta$ then K^2 is between 0 and 1 and it is never negative. So, now, we have to go from θ to z . So, let us express. So, this is our relation which is allowing us to do this. So, I can write this as $\theta = 2 \sin^{-1} z$.

And so, $\frac{1}{2} d\theta$ is equal to $\frac{1}{\sqrt{1-z^2}} dz$. If I substitute it into this equation, I would write to replace θ by z . So, the equation becomes $\int \frac{dz}{\sqrt{1-z^2}}$ is equal to $\int \frac{dz}{\sqrt{1-K^2 z^2}}$.

Now, we can do one more round of substitutions, but before we do that let me pull out. So, I can cancel the 2 and the 2 here and then I have dz by I will pull out that K^2 from this part and so, the K^2 will come out as K . And this is z by K whole square and now, let me substitute z by Kz .

I will define it as some ζ . So, once again dz is equal to $K d\zeta$ and if you express it in terms of ζ then this just becomes $\int \frac{K d\zeta}{K \sqrt{1-K^2 \zeta^2}}$ into $\int \frac{d\zeta}{\sqrt{1-\zeta^2}}$.

(Refer Slide Time: 07:00)

$$\left(\frac{d\theta}{dt}\right) = \pm 2\omega_0 \left[\sin^2\left(\frac{\theta}{2}\right) - \sin^2\left(\frac{\theta_0}{2}\right) \right]^{1/2}$$

$$\Rightarrow \pm 2\omega_0 dt = \frac{d\theta}{\left[\sin^2\left(\frac{\theta}{2}\right) - \sin^2\left(\frac{\theta_0}{2}\right) \right]^{1/2}}$$

$$\sin\left(\frac{\theta}{2}\right) \equiv z, \quad \sin\left(\frac{\theta_0}{2}\right) \equiv k \quad 0 \leq k^2 \leq 1$$

$$\frac{\theta}{2} = \sin^{-1}(z)$$

$$\frac{z}{k} \equiv q$$

"The symbol used for z/k is the greek alphabet xi and not zeta. It is incorrectly mentioned as zeta"

So, what we have done, you can see why we are doing this. So, what we are doing is we are going from theta to z and from z to zeta. You can see why we are doing this, because we want to convert this into a standard form of an elliptic integral ok and you can already see that this is coming in the form of an elliptic integral that we have seen earlier.

So, now we can integrate both sides and then express the right hand side in terms of elliptic integrals, let us do that. Now, before we go further let us keep track of the initial conditions. So, I will put a box here and recall that my initial condition was theta of 0 is equal to theta 0, theta dot of 0 d theta by dt was chosen to be 0.

I went from theta to z and the transformation was this. So, z of 0 so, when theta is 0. So, at t equal to 0 theta is theta 0. So, this is sin theta naught over 2 and z dot of 0 you can see is 0;

that you can see very easily from this equation. If you take the derivative with respect to time on both sides, you will get a dz by dt on the right hand side.

You will have to take the derivative of $\sin \theta$ by t with θ by 2 with respect to time, that will give you a $\cos \theta$ by 2 into $\dot{\theta}$. If you apply this equation at t equal to 0 then it is $\cos \theta$ by 2 which is $\cos \theta$ naught by 2 into $\dot{\theta}$ and $\dot{\theta}$ is 0, hence $\dot{z}$ is 0.

So, our initial conditions from θ to z transformed like this and let us see what do they transform on ξ . So, ξ of 0 ξ by definition is z by K , z of 0 is $\sin \theta$ by 2 $K \sin \theta$ naught by 2 and K is also defined as recall that K is defined as $\sin \theta$ naught by 2. So, ξ of 0 is normalized to one. You can also see that $\dot{\xi}$ of 0 is equal to 0 alright. So, these are our initial conditions on the three variables.

(Refer Slide Time: 09:42)

Handwritten mathematical derivation on a pink background:

$$\left\{ \frac{d\xi}{dt} = \pm \omega_0 \sqrt{1-k^2\xi^2} \sqrt{1-\xi^2} \right. \quad \left. \begin{aligned} &\xi(0) = 1 \\ &\dot{\xi}(0) = 0 \end{aligned} \right\} \text{ Automatically satisfied}$$

$$\Rightarrow \omega_0 \int_0^z dt = - \int_1^\xi \frac{d\xi}{\sqrt{1-k^2\xi^2} \sqrt{1-\xi^2}}$$

To be explained (pointing to the minus sign) *minus sign* (circled in red)

$$\Rightarrow \omega_0 z = \int_0^\xi \frac{d\xi}{\sqrt{1-k^2\xi^2} \sqrt{1-\xi^2}} - \int_0^\xi \frac{d\xi}{\sqrt{1-k^2\xi^2} \sqrt{1-\xi^2}}$$

$$= \int_0^\xi \frac{d\xi}{\sqrt{1-k^2\xi^2} \sqrt{1-\xi^2}} - \int_0^\xi \frac{d\xi}{\sqrt{1-k^2\xi^2} \sqrt{1-\xi^2}} = - \int_\xi^1 \frac{d\xi}{\sqrt{1-k^2\xi^2} \sqrt{1-\xi^2}}$$

NPTEL logo is visible in the bottom left corner.

So, now, let us rewrite what we had written in the earlier page. So, we had written $t \dot{z}$ by dt is equal to plus minus $\omega_0^2 (1 - K^2 z^2)$ into $1 - z^2$.

Notice we have also seen that the initial condition is 0, notice that this is redundant; because, in this equation in this equation if you put time t equal to 0. So, then the left hand side becomes $\dot{z}$. So, $\dot{z}$ of 0 is equal to the right hand side evaluated at time t equal to 0 and you can see that this term would take the product to 0 because z of 0 is 1.

So, the whole thing is automatically 0. So, this condition is automatically satisfied. This is not surprising; the reason is because we have derived all this with taking into account 0 velocity initial conditions. So, the 0 velocity initial condition is built in into the form of this differential equation.

In any case, this is a first order differential equation and we would not have been able to satisfy. They will only once we integrate this there will be only be one constant of integration and we cannot satisfy 2 boundary conditions or 2 initial conditions using 1 constant. So, it is this condition is automatically taken care of and we only need to determine the unknown constant that appears here using this.

So, that is consistent. So, let us continue further and so, if I integrate this equation then I will write this as $\omega_0^2 \int_0^t dt$ is equal to minus and I will explain why I choose the minus sign, let me just go ahead and I will remember to explain the minus sign, I will also explain the limit, but let me write down.

So, what I have done here is I have integrated it from time t equal to 0 up to some time τ . On the right hand side, I have replaced the z that appears with a dummy variable l and I have put the z in the limit of integration this thing comes, because when time is equal to 0 z is equal to 1.

So, we are integrating from 1 to some value of z which is the value the z takes when time is τ . So, you can see that this is going to, we are integrating it up to some time t and if I

carry this forward, then you can see that I can write this as so, once again. So, we will explain why we are taking this minus sign.

But let us right now, let us take this forward with the minus sign and in the next exercise I will explain why did we choose the minus sign. So, you can see that this integral minus 1 to zeta with an integrand can be written as 0 to 1. So, what I am doing is you can see how I have written this.

This integral, I am not writing the integrand because it is the same in both the terms, but this integral 0 to 1 can be split up into 0 to some value of ξ plus zeta to some value to 1 and then this is 0 to the ξ . So, this part can be written as these, this part is just this term the first term and the third term cancels each other.

And what I have left is an integral which is ξ to 1, but what my original integral was 1 to ξ . So, this integral can just be written as minus of 1 to ξ , that is the argument using which I am splitting it like this.

(Refer Slide Time: 14:39)

[illegible]

So, the argument that I am using here is, I am writing the first integral. So, the first integral is 0 to 1 and the second integral is 0 to x_i and I am writing this as 0 to x_i plus x_i to 1 minus 0 to x_i . And this the first and the third cancelled each other and the second one can be written as minus 1 to x_i which is our original integral. So, that is the argument which I am using here ok.

So, this is useful because, you can see immediately that both the integrands are exactly in the form of elliptic integrals. Now, this is what is known as complete elliptic integral of the first kind and this is what is known as incomplete elliptic integral of the first kind. You can see this is a the first one is a definite integral, the second one is an indefinite integral.

And so, this is the first one is called complete and the second one is called incomplete and we have seen earlier that these are related to $\sin$ inverse ok. Now, there is a very standard way of

writing down the first integral, I will just use that standard notation. The standard notation so, you can see that this, the first integral the complete elliptic integral of the first kind depends on one particular parameter.

I is anyway going to be integrated over and the limits of integration are constants, they are just numbers. So, this integral is just a function of k small k . So, the way to write the complete elliptic integral is the symbol K and K is actually a function of small k , small k recall is the modulus of the elliptic function.

It is related to the shape of the ellipse. In this case small k is $\sin \theta_0/2$. So, the magnitude of small k is determined by the initial angular displacement that I am giving to the pendulum, minus this is second one is just $\operatorname{sn}^{-1}(\zeta)$. So, you can see that I can now write this as $\operatorname{sn}^{-1}(\zeta) = k^{-1} \omega_0 \tau$.

And we can rewrite that as I can shift the sn to the other side that would give me a ζ of τ is sn and recall now, that I am going to now remember that sn actually depends on 2 arguments the first one is u . So, the value of u is $K(k) - \omega_0 \tau$ and the second one is small k itself.

So, you can see that we have solved the pendulum in this form, in terms of the sn function. Let us go back to our old variables; we had recall that we had gone from θ to z to ζ .

(Refer Slide Time: 18:29)

$$\theta(z) = 2 \sin^{-1} \left[\sin(\theta_0/2) \operatorname{sn} \left\{ K(\sin \theta_0/2) - \omega_0 \tau, \sin(\theta_0/2) \right\} \right]$$

Exact soln to the NLP for $\theta(0) = \theta_0, \dot{\theta}(0) = 0$

QUALITATIVE FEATURES $\boxed{\omega_0^2 = \frac{g}{L}} \rightarrow \text{Linearised frequency (ind. of } \theta_0)$

PHASE PORTRAIT

So, so if you do the reverse transformation, you can show that theta as a function of tau is equal to $2 \sin^{-1} \sin \theta_0 \operatorname{sn} \theta_0 \tau$.

I am replacing all the small case with $\sin \theta_0/2$, sn has two arguments. This is the exact solution to the non-linear pendulum for theta is equal to theta naught, theta dot is equal to theta of 0 is equal to theta naught theta dot of 0 is equal to 0 or other complicated looking formula.

You can see that the sine inverse comes, because we have we had written our answer in terms of zeta and then when we go back from zeta to z to theta there is a sine transform in this. So, you can see that there is a transform which expresses z as $\sin \theta_0/2$. So, this is the transform that I am talking about.

So, $\sin \theta$ by 2 is equal to z . So, when we wrote down our final exact answer in terms of z , we have to go back to first z and then we have to go back to θ that will involve a sine inverse; so, the final answer contains a sine inverse. Now, you can see that this is a very rather complicated looking formula.

It is difficult to visualize what does the solution look like, one can anticipate that θ will be an oscillatory function it is an oscillatory function; however, this is telling us that for large angles θ naught much greater than let us say 1, it is not going to be a sinusoidal or a cosine function of time.

We will plot this later, when we do perturbation methods at that time I will show that even if we did not know elliptic functions we can solve this equation in an approximate manner using perturbative techniques, at that time we will compare this exact solution with the perturbative solution.

Now, let us explore this solution a little bit further in order to understand what are the qualitative features, what are the qualitative features of a non-linear oscillator, this represents a non-linear oscillator and so, it is interesting to ask what are the qualitative features of a non-linear oscillator.

So, for that we can either plot this function or we could try to extract some other information from it and see what can we understand qualitatively about a non-linear oscillator. We will definitely plot this as I said earlier, but let us explore a more qualitative way of understanding the important features of a non-linear oscillator which distinguishes it from a linear oscillator.

Recall that we have found that the linear oscillator when $\sin \theta$ is replaced by θ then ω^2 was given by g/l , I had also pointed out that the frequency, the linearized frequency or other frequency squared is independent of θ naught.

Now, would this also continue to be true for a non-linear oscillator would the time period of the pendulum remain the same independent of how much I give it any. So, if I take 2 identical

pendulums and under identical conditions, if I start one at an angle of 1 degree, it would oscillate at a small angle and if I leave it the other one at an angle of 45 degrees, it would oscillate on either side up to angle 45 degree.

Would the time period of both the pendulums be the same? Linear theory says yes, they would be the same. The question is for initial angles as large as 45 degree, is the linearized approximation a good approximation? So, for that we will explore something called a phase portrait, which will tell us the qualitative features of the non-linear ordinary differential equation that we have just solved exactly.

So, this is a very useful tool of visualization particularly, when there is only 1 or at most 2 degrees of freedom, in this particular case the phase portrait can be drawn quite easily, we will do it in the next video.
