Lecture - 12
Time period of the non-linear pendulum

We were looking at the phase portrait and we had said that the phase portrait will help us understand the qualitative features of the non-linear pendulum. Let us write the equation of motion of a non-linear pendulum once again.

(Refer Slide Time: 00:27)

$\theta(t) = 2 \sin^{-1} \left[\sin(\theta_0/2) \operatorname{sn} \left\{ K(\sin(\theta_0/2)) - \omega_0 \tau, \sin(\theta_0/2) \right\} \right]$
 Exact solⁿ to the NLP for $\theta(0) = \theta_0, \dot{\theta}(0) = 0$
 QUALITATIVE FEATURES $\omega_0^2 = \frac{g}{l} \rightarrow$ Linearised frequency (ind. of θ_0)
 PHASE PORTRAIT $\frac{d^2 \theta}{dt^2} + \omega_0^2 \sin \theta = 0$
 N^{th} order o.d.e. $\rightarrow N$ 1st order o.d.e's
 $(N=2)$ 2nd order o.d.e. $\rightarrow 2$ 1st order o.d.e's
 $\theta = X(t), \frac{d\theta}{dt} = Y(t)$
 governing eqⁿ $\left\{ \begin{array}{l} \frac{dY}{dt} + \omega_0^2 \sin(X) = 0 \\ \frac{dX}{dt} = Y(t) \end{array} \right\}$
 $\frac{d}{dt} \begin{pmatrix} X \\ Y \end{pmatrix} = \begin{pmatrix} Y \\ -\omega_0^2 \sin(X) \end{pmatrix}$
 $(X^*, Y^*) \rightarrow$ fixed pts.
 $\begin{cases} X=0, Y=0 \\ X=\pi, Y=0 \end{cases}$

The basic idea of drawing a portrait is the following. If we have an n th order o d e, the idea of a phase portrait is to convert it into N first order ode's. So, if we have an N -th order ode it

need not be linear it can be linear or non-linear that does not matter. The idea is to first convert it into N 1st order ode's.

In our case we have a 2nd order ode. So, N is equal to 2 for us. So, we will convert a 2nd order ode to 2 1st order ode's. This ode's will typically be non-linear and will also be coupled to each other. So, let us see how we do this.

So, the first thing is to rewrite theta as another variable X , then the derivative of theta and call it another variable Y ; obviously, X and Y are functions of time just as theta and $d\theta/dt$ are both functions of time. Now, we go back to our governing equation and we see how can we write it as a first order equation.

You can see that if I think of this the first term as dY/dt then it is a first order equation in Y . So, let me write it as $dY/dt + \omega_0^2 \sin X = 0$; that is my first equation for the evolution of the variable Y . What about the evolution of the equation variable X ?

We have to write one more, so I need one more, dX/dt . You can immediately see, that if you take this equation theta is equal to X of t this is a definition. If you take this and differentiate it you would get dX/dt is equal to $d\theta/dt$, but we have defined $d\theta/dt$ to be Y . So, dX/dt is just Y . This follows from the definition.

So, this is the governing equation rewritten as a first order evolution equation for the variable Y , this is from the definition of X and Y .

So, have we written it as a set of 2 1st order ordinary differential equations; you can see that we have, let me use the symbol $\dot{X}$. So, this is $\dot{X}$. So, $\dot{X}$ is equal to Y of t . $\dot{Y}$ which is this is equal to minus $\omega_0^2 \sin X$. Those two are our equations which govern how X and Y evolve in space.

(Refer Slide Time: 04:32)

$$\theta(z) = 2 \sin^{-1} \left[\sin(\theta_0/2) \operatorname{sn} \left\{ K(\sin \theta_0/2) - \omega_0 z, \sin(\theta_0/2) \right\} \right] \}$$

Exact soln to the NLP for $\theta(0) = \theta_0, \dot{\theta}(0) = 0$

QUALITATIVE FEATURES $\boxed{\omega_0^2 = \frac{g}{L}} \rightarrow \text{Linearised frequency (ind. of } \theta_0)$

PHASE PORTRAIT $\boxed{\frac{d^2\theta}{dt^2} + \omega_0^2 \sin \theta = 0}$

N^{th} order o.d.e. $\rightarrow N$ 1st order o.d.e.'s
 $(N=2)$ 2nd order o.d.e. $\rightarrow 2$ 1st order o.d.e.'s

$\dot{X} = Y(t)$
 $\dot{Y} = -\omega_0^2 \sin(X)$

"These equations govern how X and Y evolve in time (and not space as incorrectly mentioned)"

Let us now plot X and Y and identify some important features of this equation. Notice that, this these two set of equations say that if you choose X is equal to 0 and Y equal to 0. So, this tells you this equation is a non-linear equation, they are coupled to each other, it is non-linear because there is a sin X term they are coupled to each other. And these tell you that if I start from a certain value of X and a certain value of Y at X equal to at time equal to 0; how will X change in time and how will Y change in time.

So, I can draw an X Y plane and I can start at a certain point on that plane; that would be equivalent to setting some initial conditions. I can and I can draw trajectories on that plane that trajectories will be governed by these two equations. In particular note that there are some special points in the plane such that if I use those if I start with those points I will not go

anywhere. By definition those points will be solutions where the right hand side should go to 0.

If with the right hand side of both the equations, if there are such special some special points X^* and Y^* such that $\dot{X} = 0$ and $\dot{Y} = 0$, then you can immediately see that the point is if you start at that point you remain at that point you do not go anywhere.

Those points are called equilibrium points in this context this is the base state or they are also called in the language of phase portraits they are also sometimes called fixed points. You can see immediately see that $X = 0$ $Y = 0$ is a fixed point. What does that physically imply?

It implies that if you take a pendulum hang it vertically downward at its equilibrium position do not give it a initial velocity; $X = 0$ is $\theta = 0$, $Y = 0$ is $\dot{\theta} = 0$. So, if I start my pendulum at the lower most position, do not give it any initial velocity; the pendulum is going to stay there. This is just a mathematical way of saying this simple fact.

You also see that there is a non trivial fixed point of these equations, $X = \pi$ $Y = 0$. This is telling us again one more physical equilibrium situation that if I take the pendulum. So, let us say I have this pen and this is like a pendulum is pivoted here and if the point is here and if I do not give it an initial velocity this is a fixed point of the system, but I can also take it to the topmost point the angle is now π .

(Refer Slide Time: 07:31)

So, X is equal to π I do not give it any initial velocity we know that this is also a fixed point, if you leave the pendulum here it stays there. The reason why it falls down is because this is an unstable point, whenever we try to put it here we always introduce some perturbations and the perturbations causes it to fall. But if you in principle if you could do a very careful experiment where you do not inject any perturbation and bring it exactly at the vertical position it will stay there.

So, these are the two fixed points, of course mathematically you can put more. You can put X is equal to $m\pi$ where m is plus minus 1 plus minus 2 plus minus 3. Those points do not give more physical solutions they are just repetitions of the same two physical points the 0 the lowermost point and the topmost point.

So, this so, X is equal to 0 Y equal to 0 and X is equal to π Y equal to 0 are the two fixed points of this system. We also know that $(0, 0)$ is stable $(\pi, 0)$ is unstable, we also intuitively know this from experience. Now let us draw the phase portrait of a pendulum of this non-linear pendulum and let us examine the trajectories on the phase portrait. This plot of X and Y is called the phase portrait. Let us draw the phase portrait for this pendulum.

(Refer Slide Time: 08:59)

I have already drawn it here you can see that this is X and this is Y . Now let me explain how I have plotted these trajectories. Our equation was so, I will just write it here; our equation was Y dot is equal to minus $\omega_0 \sin X$ and X dot is equal to Y . If I divide both the equations then I get the dt cancels out dY by dX is equal to minus $\omega_0^2 \sin X$ divided by Y .

This is an equation which can be readily integrated. If I integrate it then I get Y^2 over 2 minus $\omega_0^2 \cos X$ is equal to constant integral $\sin X$ is equal to minus $\cos X$. Now

you can see that on the X Y plane I can choose different values of the constant and I can plot curves in the implicit form Y and X, this is what I have drawn here.

The X axis is the horizontal axis the Y axis is the vertical axis. I have used you can see that I can write it in this form if you want to go from the implicit to the explicit form I can write this as there is a half and there is plus minus. So, for any value of c you will get a curve and for every value of c you will get two such curves; one on the upper half plane and one on the lower half plane.

I have plotted it for different-different values of c. So, these are what are known as phase space trajectories. For each value of c we get a phase space trajectory. What is the physical meaning of c? You can see that c is related to the energy of the system, c is not exactly energy it is a function of the energy.

(Refer Slide Time: 11:31)

In fact, this equation is nothing but another version of an equation we have already written before.

(Refer Slide Time: 11:48)

Energy of the pendulum (at any time t) is:

$$\frac{1}{2} m \left(\frac{ds}{dt} \right)^2 + mgl(1 - \cos \theta) = mgl(1 - \cos \theta_0) \}$$

$$\Rightarrow \frac{1}{2} ml^2 \left(\frac{d\theta}{dt} \right)^2 + mgl(1 - \cos \theta) = mgl(1 - \cos \theta_0)$$

$$\Rightarrow \frac{1}{2} \left(\frac{d\theta}{dt} \right)^2 = \left(\frac{g}{l} \right) [\cos \theta - \cos \theta_0] \leftarrow$$

$$\left\{ \Rightarrow \left(\frac{d\theta}{dt} \right)^2 = 2\omega_0^2 [\cos \theta - \cos \theta_0] \leftarrow \omega_0^2 \equiv g/l \right.$$

$$\Rightarrow \left(\frac{d\theta}{dt} \right)^2 = 2\omega_0^2 [1 - 2\sin^2(\theta/2) - 1 + 2\sin^2(\theta_0/2)]$$

$$\Rightarrow \left(\frac{d\theta}{dt} \right)^2 = 4\omega_0^2 [\sin^2(\theta_0/2) - \sin^2(\theta/2)] \left. \right\} \leftarrow$$

So, if you if we go back to our old equations then you can see that the equation that we wrote down here is actually just being written down there you know on the face portrait in terms of X and Y ; $d\theta$ by dt is $X Y$ square. So, if you bring the 2 to the left hand side this is half Y square minus ω_0 square $\cos X$ is equal to minus ω_0 square $\cos \theta_0$.

So, you can see that the constant that we have in our phase portrait is actually related to the energy, it is not quite the energy because something has been subtracted from energy by the time we arrive at this step. So, it is a function of the energy; is actually a function of the

energy e or the initial energy this is a conservative system. So, the energy stays the same at all times.

Now by choosing different-different values of this constant, you are essentially initializing the system by giving it different amounts of energy. Note that these each of these trajectories each trajectory corresponds to a certain amount of energy. So, if I take my pendulum and give it leave it at 20 degree angle I am injecting it certain amount of gravitational potential energy with that energy it will keep oscillating at twenty degrees.

If I leave it at a larger angle it will execute it has it starts with a bigger energy. So, it will execute a more energetic motion, but it will still be periodic. You can see that each of these trajectories have a sense. So, you can work this out that each of these trajectories goes in the clockwise sense.

In particular there is one such trajectory which corresponds to these two. Notice that we had drawn these trajectories for the special case of ω_0^2 by assuming that ω_0^2 is equal to 1. Now, there are 2 kinds of very special trajectories which occurs when c is equal to 1.

You can see that if c is equal to plus 1 then I get these two trajectories. What is special about them? These trajectories separate two kinds of solutions; we have one kind of solutions which are represented by this, these are oscillatory solutions whereas, these are rotary solutions.

So, physically what does this mean? It means that if you give it an initial energy such that if you leave it here then this is an oscillatory solution. But if I start from this angle let us say and I give it so, and I give it a kick which is so hard that it actually goes over the top and comes back. Then you can see that this pendulum is going to have a rotary solution. So, these kind of solutions are rotary solutions.

So, these special trajectories separate two kinds; outside them we have rotary solutions, inside them we have oscillatory solutions. It is now possible to understand why did we choose a negative sign in our earlier exercise.

(Refer Slide Time: 15:13)

$$\Rightarrow \left\{ \frac{d\xi}{dt} = \pm \omega_0 \sqrt{1-k^2\xi^2} \sqrt{1-\xi^2} \right. \quad \left. \begin{matrix} \xi(0)=1 \\ \dot{\xi}(0)=0 \end{matrix} \right\} \text{ Automatically satisfied}$$

$$\Rightarrow \omega_0 \int_0^\tau dt = - \int_1^{\xi} \frac{d\xi}{\sqrt{1-k^2\xi^2} \sqrt{1-\xi^2}}$$

To be Explained

minus sign

$$\Rightarrow \omega_0 \tau = \int_0^{\xi} \frac{d\xi}{\sqrt{1-k^2\xi^2} \sqrt{1-\xi^2}} - \int_0^{\xi} \frac{d\xi}{\sqrt{1-k^2\xi^2} \sqrt{1-\xi^2}}$$

Complete elliptic integral of the 1st Kind " " " " " "

$$\Rightarrow \omega_0 \tau = K(k) - \text{sn}^{-1}(\xi) \Rightarrow \text{sn}^{-1}(\xi) = K(k) - \omega_0 \tau$$

$$\xi(\tau) = \text{sn}[K(k) - \omega_0 \tau, k]$$

So, here recall that we have chosen a negative sign. You can see that this is an expression for $d\xi/dt$. I am starting the pendulum at some initial angle $\theta(0)$ that corresponds to $\xi(0) = 1$. So, on the phase portrait, I am starting somewhere on the X axis and there will be a trajectory which will be going like this which will be passing through that point in that sense.

So, you can immediately see that I will be going into the negative lower half of the plane, ok. So, the that the lower part of the curve is identified by this minus sign, ok, so that is why we

chose the negative sign. You can also see that the fixed points on this is this, this, this and so on.

This is the stable fixed point. That point is the unstable fixed point. You can see that there are two trajectories which are coming into the fixed point and there are two trajectories which are going out of the fixed point and all of these are this sense, ok. So, this fixed point is the same as that fixed point.

Now the question is, if you make the if you keep going so, you can see that the lower value there is a lower value of c there is no upper value of c you can give it as much energy as you want, but there is a minimum value of c and that is minus 1.

(Refer Slide Time: 17:29)

So, this is the minimum value that we can give to c . However, there is no upper limit on what is the maximum value. So, for example, if we give 2 then we recover this trajectory and the negative of that is this trajectory. So, we just take the plus and the minus sign there and give it c is equal to plus 2. If we give it 3, then our trajectory goes even further. So, these are rotary solutions which move faster and faster.

Now let us ask that for the oscillatory solutions. So, I am looking at these kind of solutions, where it goes like this. As I go from smaller and smaller amplitude to larger and larger amplitude what happens to the time period. Looking at this phase portrait, it is not obvious that the time period is independent of the amplitude. In this case is T a function of θ_0 that is the question that we are asking. So, let us answer that question in an approximate manner.

(Refer Slide Time: 18:35)

$\pm 2\omega_0 dt = \frac{d\theta}{\sqrt{\sin^2(\theta_0/2) - \sin^2(\theta/2)}}$ $T = \text{time period}$

$2\omega_0 \frac{T}{4} = \int_0^{\theta_0} \frac{d\theta}{\sqrt{\sin^2(\theta_0/2) - \sin^2(\theta/2)}}$

$\Rightarrow \omega_0 \frac{T}{2} = \int_0^{\theta_0} \frac{d\theta}{\sqrt{\sin^2(\theta_0/2) - \sin^2(\theta/2)}}$

$z = \frac{\sin(\theta/2)}{\sin(\theta_0/2)}, \quad k \equiv \sin(\theta_0/2)$

$T = \frac{4}{\omega_0} \int_0^1 \frac{dz}{\sqrt{1 - k^2 z^2} \sqrt{1 - z^2}} = \frac{4}{\omega_0} K(k)$

$k \ll 1$

So, we have seen that; now suppose we leave the pendulum at this θ some value of θ naught we are interested in the oscillatory solutions, not the rotary solution and we are trying to compute the time period of the oscillatory solution. If I leave it at a positive value of θ naught, I expect the pendulum to go to the other side at the same angle θ naught and then come back.

So, in this part if I split these trajectories and it will come back up to here. So, if I split this trajectory into four parts then it goes if the total time is T , then when it is here so this is time T equal to 0 this is T by 4 this is $2T$ by 4. Then when it again comes back this is $3T$ by 4 and then this is T . By symmetry I know that each of these parts takes equal amount of time.

So, I will just T is the time period, and so I am just going to integrate this equation in the last part when it goes from here to there. So, my time is varying from $3T$ by 4 to T . In the phase portrait, what does that correspond to? In the phase portrait it corresponds to this part of the motion.

It just corresponds to this part of the trajectory; this one fourth of the trajectory. This entire thing which looks like an ellipse, but really is not an ellipse can be split up into four parts its very symmetric. So, it can be split up into four parts. I am just looking at the time taken to go in the last part and I will multiply that by 4; that will give me the time period of the total motion.

So, I say and you can immediately see that now I have to take the plus sign because I am integrating in the upper half of the phase space portrait. So, if I integrate this it will look like $\int_0^{T/4} \omega \, dt$ from angle the angle is 0 when T is equal to $3T$ by 4 and the angle is again θ naught when t is equal to capital T . So, $3T$ by T minus $3T$ by 4 is T by 4 and I get this integral. So, we can write this as; now it is essentially the same thing.

Now, I can immediately do the same exercise that we did earlier, convert this into an elliptic integral. However, I am going to do an approximation on the elliptic integral and not use the

elliptic functions per se. So, let us see how we do that. So, I define Z is equal to $\sin \theta$ by 2 divided by $\sin \theta$ naught by 2 and K is $\sin \theta$ naught by 2. So, Z is basically $\sin \theta$ by 2 divided by K .

If we do this then it can be shown with a little bit of algebra that this equation just converts to $4 \int_0^1 \frac{dZ}{\sqrt{1 - K^2 Z^2}}$. You can see that when the upper limit is θ naught then Z is 1, so it is 0 to $1 \, dZ \sqrt{1 - K^2 Z^2}$. Let me write Z that manner into $\sqrt{1 - K^2 Z^2}$ and we have seen that this is just $4 \int_0^1 \frac{dZ}{\sqrt{1 - K^2 Z^2}}$ into big K of small k , the complete elliptic integral of the first kind.

However, we can do an approximation on this integral. Suppose I do not know what this function looks like. Let me do an approximation on this integral for small k ; k remember is $\sin \theta$ by 2. If my angle is small, but not very small I can do a Taylor series approximation and retain more and more terms in the Taylor series approximation. And the hope is that, that will give me a glimpse into what is the first correction due to non-linearity. So, let us do that.

(Refer Slide Time: 23:48)

$$\begin{aligned}
 T &= \frac{4}{\omega_0} \int_0^1 \frac{dz}{(1-z^2)^{1/2}} [1-k^2 z^2]^{-1/2} \\
 &= \frac{4}{\omega_0} \int_0^1 \frac{dz}{(1-z^2)^{1/2}} \left[1 + \frac{1}{2} k^2 z^2 + \frac{3}{8} k^4 z^4 + \dots \right] \\
 &= \frac{4}{\omega_0} \left[\frac{\pi}{2} + \frac{k^2}{2} \int_0^1 \frac{z^2 dz}{(1-z^2)^{1/2}} + \dots \right] \\
 &\quad \left(\int_0^1 \frac{1-(1-z^2)}{(1-z^2)^{1/2}} dz = \sin^{-1} z \Big|_0^1 - \int_0^1 \sqrt{1-z^2} dz \right) \\
 &\rightarrow = \frac{4}{\omega_0} \left[\frac{\pi}{2} + \frac{\pi k^2}{8} + \dots \right]
 \end{aligned}$$

So, you can see that T is equal to 4 by ω_0 $\int_0^1 \frac{dz}{(1-z^2)^{1/2}}$ by 1 minus Z square to the power half and I will take the other term because that contains K . So, this is 1 minus K square Z square to the power minus half. And now I can use binomial theorem for small k and expand this.

And if I just use binomial theorem I get; now I can integrate term by term. So, the first term is just $\sin^{-1} Z$ when I impose the limits that gives me π over 2 . The second term is this integral 0 to 1 ; I will put a K square here by $2 Z$ square dZ divided by 1 minus Z square to the power half plus dot dot dot let us not worry about the other terms.

Now, this term this integral can be easily done using elementary methods. So, you can for example, write it as 1 minus or rather 1 minus 1 minus Z square divided by 1 minus Z square to the power half dZ and then the first integral is just $\sin^{-1} Z$ from 0 to 1 minus square

root 1 minus Z square 0 to 1 dZ. And this can be easily solved with the trigonometric substitution.

If you do all of these things you will just find that the second integral is just pi by 8 or rather pi by 4. So, I am just going to write that this is equal to 4 by omega naught into pi by 2 plus pi K square by 8 plus dot dot dot.

(Refer Slide Time: 26:27)

The image shows a handwritten derivation of the period T of a simple pendulum. The derivation starts with the formula for the period of a simple pendulum, $T = 2\pi \sqrt{\frac{l}{g}}$, and then uses a binomial expansion to approximate the period for small angles. The expansion is written as:

$$T = 2\pi \left(\frac{l}{g}\right)^{1/2} \left[1 + \frac{k^2}{4} + \dots \right]$$

where $k = \sin(\theta_0/2)$. The next term in the expansion is shown as $\frac{\sin^2(\theta_0/2)}{4}$, which is labeled as a " θ_0 dependent term". The final expression is:

$$T = 2\pi \left(\frac{l}{g}\right)^{1/2} \left[1 + \frac{\sin^2(\theta_0/2)}{4} + \dots \right]$$

The NPTEL logo is visible in the bottom left corner of the slide.

So, our expression for T looks like T is equal to 4 omega naught is 1 by g to the power. So, it was 1 by omega naught. So, it becomes 1 by g to the power half, and then we have a pi by 2 plus pi K square by 8 plus dot dot dot. Incidentally the next term can also be calculated with a little bit effort and then that term is 9 pi K 4 by 128. It just requires doing one more integral.

And you can write this as T is equal to; if I pull out a π by 2 out of the bracket then I have $2\pi \sqrt{l/g}$ the familiar time period of a simple pendulum $1 + \dots$. If I pull out a π by 2 outside then this becomes K^2 by 4 plus dot dot dot. And this is telling us something very very interesting.

$1 + \sin^2 \theta / 2 + \dots$ divided by 4 plus dot dot dot dot. This is telling us that the time period of a pendulum of a non-linear pendulum is not independent of θ naught. This is an approximation to the time period notice that we have ignored higher order terms in the dot dot dot expressions.

So, this is a θ naught dependent term. This is a very important conclusion that we will see again when we meet interfacial waves; non-linear interfacial waves particularly. We will see that linear interfacial waves are governed by a dispersion relation where the amplitude of the wave does not figure in the dispersion relation.

Here also if you take a linearized pendulum the time period of the pendulum or the frequency of the pendulum does not depend on the amplitude of initial perturbation that is given to the pendulum. However, that is not the complete story the; an actual pendulum this is there is an actual dependence of the time period.

And if you take 2 pendulums and leave one at 1 degrees and the other at 45 degrees their time periods will be slightly different. This will have an effect on their motion at long times. We will see that when we do perturbation methods.
