Lecture - 14
Perturbation methods (contd..)

We were looking at the order symbol in our previous example and we had just defined a function f of ϵ to be of the order another function g of ϵ , if this criteria was satisfied.

(Refer Slide Time: 00:25)

$\lim_{\epsilon \rightarrow 0} \begin{cases} \sin \epsilon = O(\epsilon) \checkmark \\ \sin(7\epsilon) = O(\epsilon) \checkmark \\ \sin(2\epsilon) - 2\epsilon = O(\epsilon^3) \checkmark \\ J_0(\epsilon) = O(1) \checkmark \\ J_0(\epsilon) - 1 = O(\epsilon^2) \checkmark \end{cases}$

$f(\epsilon) = O[g(\epsilon)]$
 $\lim_{\epsilon \rightarrow 0} \left| \frac{f(\epsilon)}{g(\epsilon)} \right| < \infty$

$\sinh(\epsilon) = O(\epsilon)$
 $\frac{\sinh(\epsilon)}{\epsilon} = \frac{e^\epsilon - e^{-\epsilon}}{2\epsilon} = \frac{(1 + \epsilon + \frac{\epsilon^2}{2} + \frac{\epsilon^3}{6} + \dots) - (1 - \epsilon + \frac{\epsilon^2}{2} - \frac{\epsilon^3}{6} + \dots)}{2\epsilon}$
 $= \frac{2\epsilon + \frac{2\epsilon^3}{6} + \dots}{2\epsilon} = 1 + \frac{1}{3}\epsilon^2 + \dots$

$\sinh(x) = \frac{e^x - e^{-x}}{2}$

We also looked at a couple of simple examples and we found that $\sin \epsilon$ is of the order ϵ , $\sin 7\epsilon$ is also of the order ϵ , $\sin 2\epsilon - 2\epsilon$ is of the order ϵ^3 .

$\frac{1}{2}\epsilon$ is of the order 1 and you can try it for yourself using the same infinite series representation that I had given you earlier for $\frac{1}{2}\epsilon$, then $\frac{1}{2}\epsilon$ minus 1 is of the order ϵ^2 . Once again I would like to repeat that the precise value of when we particularly when we say something is of the order 1 the limit actually should be finite.

Whether the limit is actually 1 or not is not important. As long as the limit is finite even, if it the number in the limit comes out to be 1000 the function is still of the order 1. So, now, let us take some more examples. So, for example, $\sinh \epsilon$ is of the order ϵ . This is a claim, let us see whether this is true or not.

So, recall the $\sinh x$ is defined as $\frac{e^x - e^{-x}}{2}$. So, if I use that then, I would like to take this so, $\sinh \epsilon$ would be $\frac{e^\epsilon - e^{-\epsilon}}{2}$ and if I. So, I would like to divide this by ϵ and then take the limit.

So, there is a 2ϵ here. And, then if I expand e to the power ϵ in a Taylor series, then this is $1 + \epsilon + \frac{\epsilon^2}{2} + \frac{\epsilon^3}{6} + \dots$ minus $1 - \epsilon + \frac{\epsilon^2}{2} - \frac{\epsilon^3}{6} + \dots$. And, this whole thing gets divided by 2ϵ .

Now, if I add up there will be some things which cancel out. So, the first term would be 2ϵ . ϵ^2 would cancel each other out and then, we would have $\frac{2\epsilon^3}{6} + \dots$ divided by 2ϵ . And you can see that the first term is 1, if I divide by the denominator and then, there are terms the first term will be something into ϵ^2 .

This something is finite plus something into ϵ it would this will be ϵ^5 . So, this will be ϵ^4 . So, you can see that each of these terms plus \dots , everything here in the limit of ϵ going to 0 is going to 0 and this limit is just going to go to 1. So, $\sinh \epsilon$ by ϵ is indeed of the order ϵ .

Once again, I am emphasizing that even if this limit did not evaluate to 1, but instead evaluate to let us say 100 which is not true in this case, but let us say we took something, where the limit evaluated to 100 as long as we get a finite number it is the statement is correct.

(Refer Slide Time: 03:51)

$\cot \epsilon = O(\epsilon^{-1}) \checkmark$
 $\lim_{\epsilon \rightarrow 0} \frac{\cot(\epsilon)}{\epsilon^{-1}} = \epsilon \frac{\cot(\epsilon)}{\sin \epsilon}$
 $= \epsilon \cdot \frac{1}{\epsilon} = 1$

Unperturbed: $\epsilon = 0$
 Base/Equilibrium state
 $x^2 - 3x + 2 = 0$
 $\Rightarrow \underbrace{x^2 - 3x + 2}_{O(1)} + \underbrace{\epsilon(1 - 2x)}_{O(\epsilon)} = 0$
 $x_0 = 2 \text{ or } 1$

Simple algebraic eqⁿ \rightarrow Perturbation
 Regular Perturbation Technique (RPT)
 $x^2 - (3 + 2\epsilon)x + \epsilon + 2 = 0$
 Solve for $\epsilon \ll 1$
 $\epsilon = 0, \quad x^2 - 3x + 2 = 0$
 $\Rightarrow (x-2)(x-1) = 0$
 $x = x_0 + O(\epsilon)$

So, this is also correct. Another example, $\cot \epsilon$ is of the order ϵ to the power minus 1. So, now, how do we check this? So, let us take the ratio $\cot \epsilon$ by ϵ to the power minus 1. We are interested in this limit. So, you can bring ϵ to the numerator right \cot as $\cos \epsilon$ by $\sin \epsilon$.

Now, for sufficiently small ϵ , the first term in the Taylor series approximation of $\cos \epsilon$ is just 1. The first term in the Taylor series approximation of \sin is just ϵ . So,

this is 1. So, this is also correct. You can plot this function $\epsilon \cot \epsilon$ and you will see that it starts at 1.

So, like that we can explore many examples, but let us look at some applications of this order symbol, we are going to use this order symbol and refer to it repeatedly in this course. So, let us look at some applications. I put this in a box ok. So, now, we will solve some simple algebraic equations using perturbation.

These are what are known as regular perturbative techniques or regular perturbation technique. There is also another class of methods, which are called singular perturbation techniques, we will briefly discuss them later on. This spelling is wrong perturbation technique.

So, let us say, we have to we have a cubic equation or rather we have a quadratic equation and we have to find its roots. So, the equation is given by this. We have to solve this equation or solving implies finding its roots for ϵ less than 1. Now, of course, we can solve this exactly, this has been chosen such that there is an exact solution.

So, we all know, what is the formula for finding the root of a quadratic equation. Let us pretend for the time being that we do not remember that formula. So, let us solve this example in a perturbative fashion. So, recall what I said the first step is non-dimensionalization that include that step usually brings in an ϵ that step is already done here.

So, you already have ϵ in your equations. So, let us not worry about non-dimensionalization right now. The next thing is to check, whether at ϵ equal to 0 your problem is something which can be solved easily. So, if I set ϵ equal to 0 here, then this becomes $x^2 - 3x + 2$ is equal to 0.

This can be factorized easily into this. And so, we know that the unperturbed roots so, unperturbed is when ϵ so, unperturbed is ϵ equal to 0. This is the equivalent of

the equivalent of this in mechanical systems that we have been we have been studying so far is the base or the equilibrium state.

So, you can think of ϵ equal to 0 as our base state or equilibrium state that was an easy state to analyze nothing was moving. And in this case, in the equilibrium or the base state, we can solve this equation and find its roots easily. So, x_0 is equal to 2 or 1.

Now, our perturb problem is this with ϵ ok. And, we are interested in finding out an expression for its roots in the limit of ϵ going to 0. Let us say we do not know the formula that we all use for finding the roots of a cubic. So, let see how are we going to do this.

So, let me reorganize this equation and write it like this. So, I am collecting all the ϵ terms and putting them at the end and this is my unperturbed equation. Now, I will write this as. So, now, you can see that if you think of $f(x)$. So, you can clearly see that if I change the value of ϵ its roots are going to change for ϵ equal to 0 I have 2 n 1.

For ϵ equal to 0.1, I will have some other root slightly different from 2 n 1. For ϵ equal to 0.2, it will be again slightly different from even more different from 2 n 1 and so on and so forth. I am interested in finding an expression for those roots for the perturbed equation in the limit of ϵ going to 0.

Now, you can see that assuming that all the roots x is a symbol for the roots of this equation. If I say that in the limit of x equal to ϵ equal to 0, let us say that the roots are all order 1, which means that they are essentially finite they do not go away to infinity.

If I make this assumption, then I can evaluate the sizes of various terms in this equation. So, if x is an order 1 term, then x^2 is also an order 1 term. This is an order 1 term this is of course, an order 1 term this whole thing is an order 1 term, this is an order ϵ term the product of these two is an order ϵ term.

So, you can see that the structure of this perturbed equation is that there was an order one equation which is obtained when epsilon equal to 0. And you have added a perturbation which is probably order epsilon. So, we will say that if you have added a order epsilon perturbation to the equation, the answer to the unperturbed system might have also got perturbed by the same amount ok.

So, we will pose an expansion, we will say that the root x of the perturbed system is the root x_0 of the unperturbed system. x_0 we know is either 2 or 1, plus some correction which are order epsilon. Why is order epsilon? Because, this is order epsilon. So, let me write it in colour this we think is order epsilon. So, how are we going to write these expressions of order epsilon? We will write it like this.

(Refer Slide Time: 11:27)

$$\begin{aligned}
 x &= x_0 + \underbrace{x_1 \epsilon}_{O(\epsilon)} + \underbrace{x_2 \epsilon^2}_{O(\epsilon^2)} + \underbrace{x_3 \epsilon^3}_{O(\epsilon^3)} + \dots \quad x_0 = O(1) \\
 &\quad \underbrace{\hspace{10em}}_{O(\epsilon)} \checkmark \\
 F(\epsilon) &\equiv x_1 \epsilon + x_2 \epsilon^2 + x_3 \epsilon^3 + \dots \\
 F(\epsilon) &\checkmark = O(\epsilon) \checkmark \\
 \lim_{\epsilon \rightarrow 0} \frac{F(\epsilon)}{\epsilon} &= \frac{x_1 \epsilon + x_2 \epsilon^2 + x_3 \epsilon^3 + \dots}{\epsilon} \\
 &= \lim_{\epsilon \rightarrow 0} \left(\underbrace{x_1}_{O(1)} + \underbrace{x_2 \epsilon}_{O(\epsilon)} + \underbrace{x_3 \epsilon^2}_{O(\epsilon^2)} + \dots \right) = x_1 = O(1)
 \end{aligned}$$

We will say x is equal to x_0 which is my unperturbed root, plus a correction which is an order epsilon term in the limit of epsilon going to 0. So, I will write that correction itself as an infinite series and I will write it as a power series in epsilon. Notice that each of these terms, this is an order epsilon term this is an order epsilon square term, this is an order epsilon cube term and so on.

And that is because we are assuming that all the x_n 's are order 1. So, here we are having an order 1 term multiplying an order epsilon term. Here, we have an order 1 term multiplying an order epsilon square the product is of the order epsilon square. And now, here it is order epsilon here it is of the order epsilon cube.

Also notice that this entire thing; this entire series this combined thing this infinite thing is of the order epsilon. How do we see that? Let us call this entire thing some function of epsilon. So, F of epsilon by definition is x_1 of epsilon plus x_2 of epsilon square, plus x_3 of epsilon cube, plus dot dot dot. I am claiming that F of epsilon is order epsilon this is what I have written here.

How do I check that I take F of epsilon by epsilon and the limit epsilon goes to 0. In the numerator we have this and if I divide by epsilon, then I get x_1 plus x_2 epsilon plus x_3 epsilon square plus dot dot dot. You can see that if I take the limit epsilon goes to 0, then each of these terms will go to 0. Because the x 's are all finite and there is a epsilon to the power something in each of these terms.

So, this limit would just be x_1 , which is an order 1 number or a finite number. So, limit F of epsilon by epsilon is a finite number. So, it satisfies our definition and we can say that F of epsilon is order epsilon. I hope this is clear.

(Refer Slide Time: 14:19)

$$\begin{aligned}
 & x = x_0 + x_1 \varepsilon + x_2 \varepsilon^2 + x_3 \varepsilon^3 + \dots \\
 & \Rightarrow (x_0 + x_1 \varepsilon + x_2 \varepsilon^2 + \dots)^2 - (3 + 2\varepsilon)(x_0 + x_1 \varepsilon + x_2 \varepsilon^2 + \dots) + \varepsilon + 2 = 0 \\
 & \quad \quad \quad + (\varepsilon) + 2 = 0 \\
 & O(1) : (x_0^2 - 3x_0 + 2) = 0 \quad x_0 = 1, 2 \\
 & O(\varepsilon^1) : (2x_0x_1 - 3x_1 - 2x_0 + 1) = 0 \\
 & O(\varepsilon^2) : (x_1^2 + 2x_0x_2 - 3x_2 - 2x_1) = 0 \\
 & O(\varepsilon) : 2x_0x_1 - 3x_1 - 2x_0 + 1 = 0 \\
 & \text{Für } x_0 = 1 \quad 2x_1 - 3x_1 - 2 + 1 = 0 \Rightarrow \boxed{x_1 = -1}
 \end{aligned}$$

So, what we have said? That x is equal to x_0 plus ϵ plus dot dot dot dot. And, what we want to determine is, we want to determine these corrections x_1 x_2 x_3 and so on and so forth. Let us see how do we do this. The process is simple, we just substitute this into our governing equation and then we collect coefficients for every power of ϵ .

So, our equation let me rewrite it here. So, I am just writing the equation in the old form. So, we have to substitute it here. So, what do we obtain? We get $x = 0$ remember that we know what is the value of $x = 0$. I am just keeping it symbolic here because it will make my algebra a little bit easier.

So, I will get x^0 plus x^1 epsilon plus x^2 epsilon square, I will just go up to x^2 you can go up to higher powers if you want. So, this is squared I am substituting. So, x^2 is just this term minus 3 plus 2 epsilon into again x^0 plus x^1 plus x^2 epsilon square plus epsilon plus 2

is equal to 0. Now, our task is to collect coefficients of all powers of epsilon, we will start with order epsilon to the power 0 which is 1. So, our order 1 term we will collect.

Even before we do this, we expect the order 1 term to be just proportional to the unperturbed problem that we had written before or in other words, when we took our original equation and put epsilon equal to 0 that would give our unperturbed system. So, our order 1 terms would be I am only writing the coefficients I am not writing in this case there is no its epsilon to the power 0. So, you can see that there will be an x_0 square coming from here.

So, let me use a different colour. So, there is an x_0 square coming from here because this term is squared. So, that is an order 1 term. So, x_0 square there will not be any further order 1 terms from this first term squared. Everything will be of a higher order term, either order epsilon or order epsilon square and so on. Do we get any order 1 term from the product of these 2?

Yes, you can see that if I open up this bracket by multiplying, I will get minus 3 x_0 that does not contain any epsilon. So, that is an order 1 term everything else we will contain an epsilon. And so, we will not account for it here. Is there any order 1 term here?

Yes, plus 2 epsilon is an order epsilon term so this. So, this is the coefficient of epsilon to the power 0. What is the coefficients of epsilon or epsilon order epsilon to the power 1? So, let me call it epsilon to the power 1. So, from the first term, what do we find? The product of x_0 and x_1 epsilon will give you a twice $x_0 x_1$ that will have an epsilon as its coefficient.

We are not going to write the coefficient. Is there any order epsilon term here from the first term? No, what about the second term? If you open up the bracket, then you expect minus 3 x_1 that contains an epsilon, but you also expect the product of these two to be an order epsilon term. So, that is minus 2 x_0 . That is all we will get from here and then at the end we will have this term.

I am writing it 1 because I am collecting the coefficients of epsilon. So, this will get multiplied by epsilon, if I put it together order epsilon square. Order epsilon square also we

proceed in the same way. So, from the first square term you can see that x^1 squared would have a ϵ square. Then, the product of x^0 and x^2 would there would be a 2 there and then ϵ square there, anything else from here? No.

Then, from the product of this term, you can see that we would get a minus $3x^2$. We will also get a minus $2x^1$ and that is the coefficient of ϵ square. We can continue like this, but the important thing is if you have to solve this equation, then the power of then the coefficient of every power of ϵ has to be separately 0 because this equation as a whole is 0.

So, our equations we get a series of equations for x^0, x^1, x^2 . And so, I am just erasing the ϵ and I am just setting it equal to 0. Remember that our goal is to determine x^1, x^2, x^3 and so on. x^0 is actually known to us. So, this equation is already known to us, we have solved this equation and determined that x^0 is equal to 1 or 2.

So, x^0 is also already known to us. So, now, let us take the order ϵ equation and work out what is the value of x^1 . So, at order ϵ , we have our equation twice $x^0 x^1$ minus thrice x^1 minus twice x^0 plus 1 is equal to 0. Now, if I choose for x^0 .

So, I have two choices of x^0 for x^0 equal to 1 this equation becomes twice x^1 minus thrice x^1 minus 2 plus 1 is equal to 0 and this would imply x^1 is equal to minus 1. So, we have determined x^1 is equal to minus 1. Similarly, we can solve for the same x^0 is equal to 2. So, we have to; we have to propagate the value of x^1 here.

(Refer Slide Time: 21:27)

For $x_0 = 1, x_1 = -1$

$$O(\epsilon^2) : x_1^2 + 2x_0x_2 - 3x_2 - 2x_1 = 0$$

$$\Rightarrow 1 + 2x_2 - 3x_2 + 2 = 0$$

$$\Rightarrow x_2 = 3$$

$$x = x_0 + x_1\epsilon + x_2\epsilon^2 + \dots$$

$$x = 1 - \epsilon + 3\epsilon^2 + O(\epsilon^3)$$

For $x_0 = 2, x_1 = 3, x_2 = -3$

$$O(\epsilon) : 2x_0x_1 - 3x_1 - 2x_0 + 1 = 0 \Rightarrow 2x_1 - 3x_1 - 4 + 1 = 0$$

$$\Rightarrow x_1 = +3$$

"Notice the mistake: The $O(\epsilon)$ equation for $x_0 = 2$ is $4x_1 - 3x_1 - 4 + 1 = 0$ which leads to $x_1 = 3$ ".

So, for x_0 is equal to 1 x_1 is equal to minus 1, which we just found out. Let us write down the expression at order epsilon square; at order epsilon square we found it to be x_1^2 plus twice x_0x_2 minus thrice x_2 minus twice x_1 is equal to 0.

If I use this value of x_0 and this value of x_1 , then this equation becomes 1 plus twice x_2 minus thrice x_2 plus 2 is equal to 0. This implies x_2 is equal to plus 3. So, we have determined our expansion up to order epsilon square for the root x_0 is equal to 1 it is. So, our equation has the form x_0 plus x_1 epsilon plus x_2 epsilon square plus dot dot dot. We are not determining beyond that and we have determined that x for x_0 equal to 1 x_1 is minus 1.

So, I get minus epsilon and x_2 is 3. So, I get a plus 3 epsilon square. So, this is a perturbative expansion for one root what I am missing here? Is an order epsilon cube is an infinite series

whose order is order epsilon cube. These are further higher order corrections. What about the second root? Our base state or the unperturbed problem had 1 and 2.

So, we will have to redo this exercise for that problem also. You can check that for x_0 is equal to 2 you will get x_1 is equal to 3 and x_2 is equal to minus 3. So, first let us write the order epsilon equation, the order epsilon equation was twice x_0 minus thrice x_1 minus twice x_0 plus 1 is equal to 0.

This was our order epsilon equation and if you substitute x_0 is equal to 2, then you get twice x_1 minus thrice x_1 minus 4 plus 1 is equal to 0. So, this implies x_1 is equal to plus 3, which is what we have found here. Order epsilon square basically this equation.

(Refer Slide Time: 24:11)

For $x_0 = 1, x_1 = -1$

$O(\epsilon^2): x_1^2 + 2x_0x_2 - 3x_2 - 2x_1 = 0$
 $\Rightarrow 1 + 2x_2 - 3x_2 + 2 = 0$
 $\Rightarrow x_2 = 3$

$x = x_0 + x_1\epsilon + x_2\epsilon^2 + \dots$
 $x = 1 - \epsilon + 3\epsilon^2 + O(\epsilon^3), x = 2 + 3\epsilon - 3\epsilon^2 + O(\epsilon^3)$

For $x_0 = 2, x_1 = 3, x_2 = -3$

$O(\epsilon): 2x_0x_1 - 3x_1 - 2x_0 + 1 = 0 \Rightarrow 2x_1 - 3x_1 - 4 + 1 = 0$
 $\Rightarrow x_1 = +3$

$O(\epsilon^2): x_1^2 + 2x_0x_2 - 3x_2 - 2x_1 = 0 \Rightarrow 9 + 4x_2 - 3x_2 - 6 = 0$
 $\Rightarrow x_2 = -3$

x^1 square plus twice x naught x^2 minus thrice x^2 minus twice x^1 is equal to 0. If you substitute, you will have to substitute x naught is equal to 2 and x^1 is equal to 3. So, x^1 is equal to 3 implies this is 9, x naught is 2. So, plus 4 x^2 minus 3 x^2 minus 6 is equal to 0.

This implies x^2 is equal to minus 3, x^2 is equal to minus 3. So, one can systematically go and find better and better approximations to the problem. Let us try to understand, what exactly is this are these expressions where exactly are these expressions coming from.

So, this is one expression this is corresponding to the root 1 the unperturbed root 1 and then I will have another expression, which is $2 + 3\epsilon - 3\epsilon^2$. I am just using these three values. So, let me put this in red. So, this is one expression and that is another expression.

I have written it up to epsilon square and then I can carry forward to higher powers if I need. So, this 1 has plus order epsilon cube ok. So, let us now try to understand where does this expressions come from. For this we are going to use the exact solution.

(Refer Slide Time: 26:19)

$$\begin{aligned}
 & x^2 - (3+2\varepsilon)x + \varepsilon + 2 = 0 \quad \leftarrow \boxed{\varepsilon = 0.1} \\
 & x^{(1/2)} = \frac{(3+2\varepsilon) \pm \sqrt{(3+2\varepsilon)^2 - 4(\varepsilon+2)}}{2} \quad x^2 - 3 \cdot 2x + 2 \cdot 1 = 0 \\
 & = \frac{(3+2\varepsilon) \pm \sqrt{1+4\varepsilon(\varepsilon+2)}}{2} \quad \checkmark \quad \varepsilon \ll 1 \\
 & [1+4\varepsilon(\varepsilon+2)]^{1/2} = 1 + 4\varepsilon - 6\varepsilon^2 + \dots \\
 & x^{(1/2)} = \frac{(3+2\varepsilon) \pm (1+4\varepsilon-6\varepsilon^2) + \dots}{2} \\
 & \boxed{x^{(1)} = 2 + 3\varepsilon - 3\varepsilon^2 + O(\varepsilon^3)} \quad \checkmark \quad \boxed{x^{(2)} = 1 - \varepsilon + 3\varepsilon^2 + O(\varepsilon^3)} \quad \checkmark
 \end{aligned}$$

Our equation was x square minus 3 plus twice epsilon into x plus epsilon plus 2 is equal to 0. x 1 comma 2 the 2 roots let us say is minus b plus minus. Now, I am writing down the formula for the roots of a quadratic equation. Now, simplify this, then you can write this as the inside part if you open up the square, then you can write this as 1 plus 4 epsilon into epsilon plus 2.

Now, 1 plus 4 epsilon into epsilon plus 2 to the power half, I am just looking at the discriminant. This you can expand it in using the binomial expansion and this will have 1 plus 4 epsilon minus 6 epsilon square plus dot dot dot. This is all this is for epsilon less than 1.

So, if you now go and plug this expression into this, then you will get x 1 2 is equal to 3 plus 2 epsilon plus minus 1 plus 4 epsilon minus 6 epsilon square plus dot dot dot of course,

divided by 2. And so, this will give you for the plus 1, you will get 1 expression for the minus for the plus here you will get 1 for the minus you will get another expression.

So, corresponding to the ok. So, let me not use $x^{1/2}$ like this because $1/2$ are actually the roots also. So, this is the 1 or 2. So, the first root and this root corresponds to 2 the unperturbed root is 2. So, you will get $2 + 3\epsilon - 3\epsilon^2 + \text{order } \epsilon^3$.

The second root so, you can check which one comes from which one of them one of this expression will come from taking the plus sign the other will come from taking the minus sign. The other root is $1 - \epsilon + 3\epsilon^2 + \text{order } \epsilon^3$.

So, what perturbation is doing? Is basically it is taking the exact solution and it is expressing it in a series form. And so, we are getting this series. I leave it to you to check the accuracy of this roots. So, for example, take $x^{1/2}$ is equal to a small number compared to 1, let us say 0.1 sorry, ϵ to be a small number 0.1.

Plug it back into this equation, you will get some equation. So, in this case you will get the equation $x^2 - 3.2x + 2.1 = 0$. Calculate the exact roots of this equation from this expression using your calculator. Calculate the same roots using this and that and check the accuracy. You will find that these expressions do a reasonably good job at finding the roots.

We will continue our discussion of perturbation methods in the next video.
