Lecture - 15
Non – dimensionalisation

In the last problem, we had looked at solving for roots of a quadratic equation where the equation was slightly perturbed from a state where it was factorizable as two integers, two integer roots into a slightly perturbed state. There we I had stated that the epsilon which is typically a non-dimensional parameter and a small parameter for solving the problem perturbatively is introduced through non-dimensionalisation.

We did not discuss non-dimensionalisation for that problem. We now return to non-dimensionalisation, and what is the optimal way of doing non-dimensionalisation and introducing epsilon into our problem. The important thing to realize is that the choice of typically for a problem for a mathematical model that we want to set up in this case we will look at a simple example.

Now, later we will have to do the same for our interfacial waves problem; typically there are more than one choice for length, time, length and time scales. This leads to some kind of ambiguity for the choice of for the correct choice of non-dimensionalisation for quantities like velocity and so on. Here we have to use our physical intuition in order to choose the scales correctly. Let us look at an example.

(Refer Slide Time: 01:26)

NON- DIMENSIONALISATION

$v_0 = 130 \text{ km/hr} \approx 35 \text{ m/s} \ll \text{escape velocity}$

$\sqrt{\frac{2GM}{R_0}}$

\downarrow

$\approx 11 \text{ km/s}$

$F = m\ddot{x} = -\frac{GMm}{(R+x)^2}$

G : Univ. gravitational const.

M : mass of earth

R_0 : radius "

$G = 6.67 \times 10^{-11} \text{ m}^3 \text{ kg}^{-1} \text{ s}^{-2}$

$M = 5.97 \times 10^{24} \text{ kg}$

$R_0 = 6.37 \times 10^6 \text{ m}$

"Error: R in the denominator should be R_0 , the radius of earth"

So, let us take a simple example, where let us say we are standing on the surface of earth, and we are throwing a ball upwards at a speed v_0 . Now, of course, the distance to which the ball travels will depend on the speed v_0 . We typically if we throw with our hands, we cannot throw the ball very high. When I say very high I mean the distance that it would travel would be very small compare to for example the radius of the earth.

Let us write down some numbers to form our estimates. So, typically v_0 , I will take an upper limit on what, what is the fastest that a human hand can throw a ball. So, typically a fast bowler, for example, in cricket can throw typically at about 130 kilometers per hour. This is approximately it is slightly more than this, but approximately this is 35 meter per second. It is above 36 point something, but I have a rounded it off to 35.

So, this is, this is a representative estimate of how fast can the human hand throw. So, if we have a fast bowler in cricket throwing, the ball is expected to be thrown at a typical velocity of 35 meter per second. Now, you can see that this is much, much less than for example the escape velocity.

We all know how to estimate escape velocity. Recall that the escape velocity is given by the formula $\sqrt{2GM/R}$. Here G is the universal gravitational constant appearing in the law of gravitation, M is the mass of earth, and R naught is the radius of earth. Now, we know that when you throw a ball upwards, the acceleration the force that the earth exerts on the ball via gravity is not really a constant.

It depends on the separation between the ball and the earth, and the center of the earth. Now, typically for the speeds at which we throw a balls the distance at which it travels is so small compare to the radius of the earth that as a first approximation, it is usually safe to ignore that distance and treat the force as if it is a constant that gives us a constant value of force consequently a constant value of acceleration which we know to be small g which is 9.8 meter per second square.

Now, suppose instead of throwing 130 at 130 kilometers per hour, we throw at a much higher speed you know 10 times or may be even 100 times of that. So, this is a hypothetical situation when a where we are launching the ball not my hand, but using some kind of a mechanism which can let us say a launch it at about instead of 130 kilometers per hour, we are launching it at let us say 10 times. Let us compare it with the escape velocity.

If you estimate this, so G is 6.67. So, these are the numbers in SI units. If you calculate, if you plug in it in here, you will get approximately 11 kilometer per second. So, you can see that this is even if I launch it at 1300 kilometers per hour that is much, much less than 11 kilometers per second. So, you can see that 11 into 3600 will be much more than that.

So, now compare a hypothetical situation where I am launching it at a high speed, the speed is high enough such that I do not want to ignore the fact that the as the ball goes upwards, the

force that the earth exerts on the ball actually changes. So, I want to solve the exact equations without making an approximation that the acceleration or the force is a constant. We know how to do this. So, let us do this.

So, the exact force, so the exact expression would be, so let say this direction is X we are solving a one-dimensional problem. So, mass into acceleration because the force is always attractive it will be directed towards the center of the earth and we take all quantities in the readily outward direction to be positive, so upward direction is positive. So, the force is negative. And by Newton's law of gravitation the force is just this here small m is the mass of the body that I am launching.

(Refer Slide Time: 06:38)

NON- DIMENSIONALISATION

$v_0 = 130 \text{ km/hr} \approx 35 \text{ m/s} \ll \text{escape velocity}$
 $\sqrt{\frac{2GM}{R_0}} \approx 11 \text{ km/s}$
 $F = m\ddot{x} = -\frac{GMm}{(R+x)^2}$
 $\Rightarrow \ddot{x} = -\frac{GM}{(R+x)^2}$
 $\approx -\frac{GM}{R^2} \rightarrow -g$

G : Univ. gravitational const.
 M : mass of earth
 R_0 : radius " "
 $G = 6.67 \times 10^{-11} \text{ m}^3 \text{ kg}^{-1} \text{ s}^{-2}$
 $M = 5.97 \times 10^{24} \text{ kg}$
 $R_0 = 6.37 \times 10^6 \text{ m}$

Solve the full problem

$$\ddot{x} = -\frac{GM}{(R+x)^2} \quad \begin{matrix} x(0)=0 \\ \dot{x}(0)=v_0 \end{matrix}$$

$$= -\frac{GM}{R^2(1+\frac{x}{R})^2} = -\frac{g}{(1+\frac{x}{R})^2}$$

Now, this cancels out and so we get x double dot is equal to minus GM by R plus x square. Now, I can immediately see that for the typical velocity is which suppose we launch it at 35

meter per second or 130 kilometers per hour it would be the distance that x max the distance then the ball would travel would be far less than R .

And so when we solve this equation as a first approximation, I can just ignore the x in the denominator and just replace this as minus GM by R square. This is essentially minus g , GM by R square is g which is 9.8 meter per second square. Now, suppose I do not want to do that approximation because I want to throw the ball at increasingly higher and higher speeds.

The speeds are sufficiently large that the ball goes distance, but it is still a much bigger distance than what it would if I launch it with 35, but they are still small compare to the radius of the earth, and the velocity is still much smaller than the escape velocity. So, let us see if we can systematically set up a way of non-dimensionalising this problem choosing the scales correctly.

So, how do I choose this? So, I want to solve the full problem. I do not want to make this approximation. This is just an exercise in non-dimensionalisation followed by solving this problem using perturbative techniques. So, I do not want to make this approximation to start with.

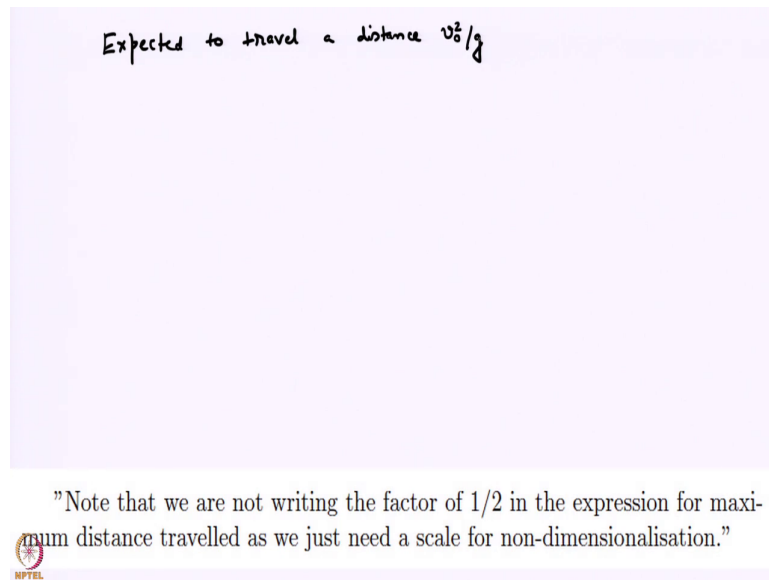

However, I also have an intuition that if v_0 is sufficiently small, then at the lowest order of approximation this should be my this problem x double dot is equal to minus g should be my first approximation. So, with that in mind let us state the problem. So, x double dot double dot is d square x by dt square is equal to minus GM by R plus x square.

Now, I will launch it at time t equal to 0 at it was at 0 my origin of my coordinate system is here. So, this is x in the vertical direction. And I am launching it with some velocity v_{naught} . Now, let us say that I am I want to write it like this. So, I pull an R out. So, it will come out as R square, and then I will have x by R whole square.

I am doing this because I want to write minus GM by R square as a single variable which is g small g . So, this is minus g by 1 plus x by R whole square. This is a very useful form because it tells us that if x max is less than R , then a first approximation is just x double dot is equal

to minus g . So, the acceleration is a constant. Now, I will let us try to first non-dimensionalised this problem appropriately.

(Refer Slide Time: 09:55)

Expected to travel a distance v_0^2/g

"Note that we are not writing the factor of $1/2$ in the expression for maximum distance travelled as we just need a scale for non-dimensionalisation."

NPTEL

So, if I launch the my projectile with the speed v_0 , I expect it to travel expected to travel a distance v_0^2 by g . You can get this from a simple estimate assume that acceleration is constant. And if you launch something with speed v_0 , then how much is the distance travelled in some time t . So, this is the maximum distance that it would travel before which after which it would start falling.

(Refer Slide Time: 10:33)

Expected to travel a distance $v_0^2/g = L \checkmark$

Time taken: $\frac{v_0^2/g}{v_0} = v_0/g = T \checkmark$

Governing: $\frac{d^2x}{dt^2} = \frac{-g}{[1 + (\frac{x}{R})]^2}$

$\tilde{x} = \frac{x}{v_0^2/g}, \quad \tilde{t} = \frac{t}{(v_0/g)}$

$\frac{[v_0^2/g]}{[Rg]} = \frac{L^2/T^2}{L \frac{L}{T^2}} = 1$

$\frac{v_0^2/g}{v_0^2/g^2} \frac{d^2\tilde{x}}{d\tilde{t}^2} = \frac{-g}{[1 + \frac{v_0^2}{Rg}\tilde{x}]^2}$

$\Rightarrow g \frac{d^2\tilde{x}}{d\tilde{t}^2} = \frac{-g}{[1 + \tilde{x}]^2} \Rightarrow \frac{d^2\tilde{x}}{d\tilde{t}^2} = \frac{-1}{[1 + \tilde{x}]^2}$

$\tilde{x}(0) = 0$
 $\frac{d\tilde{x}}{d\tilde{t}}(0) = 1$

Now, it would travel this distance time taken would be if I know my distance and if I divided by the speed with which it travels, then I get a time, so that is v_0 by g . So, this is my choice of length scale, this is my choice of time scale. This is something v_0 by g is some quantity which has the units of time v_0 square by g is some quantity which has the units of length. We are going to non-dimensionalise by these scales my governing equation.

Note that the choice of distance and the choice of time is not unique. If I had gone back to my equation and if I had not done this step where I have replaced GM by R square, then I had more dimensional quantities like G capital M and R square, in particular, I could have non-dimensionalised by my x with the radius of the earth. I encourage you to try that, but first let us do it in the intuitively correct way.

So, I expect it to travel a distance L before it starts falling back, I expect it to travel that distance in this time which is given by v_0 by T . Now, let us scale my equations. So, I will write it now in terms of $d^2 x$ by dt^2 is equal to minus g by $1 + x$ by R whole square.

This is just the equation that we had written earlier. Now, I define a non-dimensional x which is an x with the tilde which is x the dimensional x divided by something with the units of with the dimensions of length I will choose that to be v_0^2 by g – this scale. I also have to define non-dimensionalised time. I will define a new time variable t tilde, it is a non-dimensional variable. So, dimensional time divided by something with a dimensions of time which is this.

Now, using these scales, I have to non-dimensionalise my governing equation, so governing equation. Notice that this is a non-linear equation. If you solve the full problem, it is a non-linear equation in x may or may not be solvable analytically, but we are try to going we are going to try to solve this using a perturbative procedure. So, first let us non-dimensionalise it.

So, if you so I will have a v_0^2 by g in the numerator and I will have v_0^2 by g square in the denominator, and then this will become $d^2 x$ tilde by dt tilde square. And then I will have minus g $1 + x$ I can see that I will have a v_0^2 by $R g$ into x tilde whole square. You can see that this quantity v_0^2 by $R g$ is non-dimensional this is length square by time square length by time square. So, this is a non-dimensional number, I will call it epsilon.

What we have on the left hand side after cancellation, you can see is just $d^2 x$ tilde by dt tilde square, and then on the right hand side I have minus g by $1 + \epsilon x$ tilde whole square. I can cancel out the g . What about my initial conditions? My initial conditions is x tilde of 0 is anyway 0, dx tilde by dt tilde at time t equal to 0 would be 1. So, I have to solve this equation with those initial conditions. Let us estimate the value of epsilon.

(Refer Slide Time: 15:22)

$$\begin{aligned}\epsilon &= \frac{v_0^2}{Rg} \\ &= \frac{v_0^2}{R} \frac{R^2}{GM} \\ &= \frac{v_0^2}{\frac{GM}{R}} = \left[\frac{v_0}{\sqrt{\frac{GM}{R}}} \right]^2 = \left[\frac{v_0}{v_{\text{escape}}} \right]^2\end{aligned}$$

Note that we are ignoring the factor of 2 in escape velocity. This does not affect the validity of our argument that even with $v_0 = 1300$ kms/hr, $\epsilon \ll 1$

v_0 square by Rg . And you can see that if I use the formula for small g that I had given earlier, then small g was so it is $1/g$. So, it will be R^2/GM . And this is equal to v_0 square divided by GM/R . Now, this is equal to v_0 by square root GM/R whole square. What is square root GM/R ? We have seen the 2 times square root GM/R is the escape velocity; square root of 2 times GM/R is the escape velocity. So, this epsilon is nothing but v_{escape} whole square.

We have seen that even if we make v_0 as instead of 135 kilometers per hour we even if we make it 1350 – 10 times. If I make it instead of 130, I make it 1300 kilometers per hour, so it will travel 1300 kilometers in an hour. This travels 11 kilometer in a second. So, in 3600 seconds which is an hour, it will travel much much more than 1300. So, even if we make it 10 times, this ratio v_0 square, v_0 by v_{escape} .

(Refer Slide Time: 17:10)

$$\begin{aligned}
 \epsilon &= \frac{v_0^2}{Rg} \\
 &= \frac{v_0^2}{R} \frac{R^2}{GM} \\
 &= \frac{v_0^2}{\frac{GM}{R}} = \left[\frac{v_0}{\sqrt{\frac{GM}{R}}} \right]^2 = \left[\frac{v_0}{v_{\text{escape}}} \right]^2 \ll 1
 \end{aligned}$$

$\tilde{x} = \tilde{x}_0(\tilde{t}) + \epsilon \tilde{x}_1(\tilde{t}) + \epsilon^2 \tilde{x}_2(\tilde{t}) + \dots$

$\epsilon \rightarrow 0 \quad \left[\frac{d^2 \tilde{x}}{d\tilde{t}^2} = -1 \right]$

$\checkmark \quad O(\epsilon) \quad \left[\frac{d^2 \tilde{x}}{d\tilde{t}^2} = \frac{-1}{(1 + \epsilon \tilde{x})^2} \right]$
 $\tilde{x}(0) = 0 \quad O(\epsilon)$
 $\frac{d\tilde{x}}{d\tilde{t}}(0) = 1$

Let us write escape is much much less than 1. However, if we throw it at sufficiently large v_0 , those corrections to the gravitational force might become important ok. So, let us find out a way to solve the full problem in a perturbative manner. Assuming that epsilon is less than 1 is much much less than 1 and so we can solve it perturbatively, but epsilon may not be so small that we can consider force to be a constant.

So, our scale problem looks like this. How do we know that this is the correct way of non-dimensionalising? First, check whether when epsilon goes to 0, do you recover the correct equation or not that you would expect on physical grounds. So, if you said epsilon equal to 0, you get the equation $d^2 \tilde{x} = -1$, your unperturbed problem is just this.

This is just equivalent to saying that if my epsilon is extremely small ok, so in the limit of epsilon go in rather you should think of it like this, in the limit of epsilon being extremely

small, I just recover the fact that force is a constant and acceleration is just g . This is just the scale version of that.

However as if ϵ is small, but not very small, then I can use a perturbative procedure to on this equation. I encourage you to try this non-dimensionalisation by choosing other scales. So, for example, we have chosen the length, the length scale to be v_0^2/g . You could have chosen the length scale to be the radius of the earth, you could have chosen the time scale to be the time taken to cover the radius of the earth at a speed v_0 .

Try choosing those scales and non-dimensionalising your problem, and see what happens to the problem in the limit of ϵ going to 0. You will typically find that it will reduce to either something which does not make mathematical sense or it violates your basic intuition that for sufficiently small ϵ taking acceleration to be constant is a valid approximation.

So, now this non-dimensionalisation has added a non-dimensional parameter to our problem which is ϵ . In this problem, it is the square of the speed with which we are launching our projectile to the escape velocity of the earth, provided we do not launch our projectile at the escape velocity, ϵ is usually going to be much lower than 1. Let us solve this problem perturbatively, and find out what does the perturb solution look like.

So, just like before we think of this as an order ϵ term because x is an order one term. So, we are saying that x is of order one after non-dimensionalisation if we have non-dimensionalised correctly and so this whole thing is an order ϵ term. So, and the left hand side is again order 1 because there is no ϵ anywhere.

So, let us see that we are going to set up a perturbation approximation to the solution which will be x_0 which will be your function of t plus ϵx_1 plus $\epsilon^2 x_2$ plus dot dot dot. We are going to substitute this into our equation and initial conditions, and then work out the solutions to this problem at every order of ϵ .

Once we get that, then we will have to solve the differential equations at every order. And important thing to notice is that this procedure will reduce a non-linear differential equation

into a series of linear, but in homogeneous differential equations. It will be easier to solve those equations because they are linear.

However, the right hand side of the equation in homogeneity will become more and more complicated as we go to higher orders. Let us do this exercise and understand how it works. We are going to first let us work on the initial conditions first. So, our initial conditions were so let me write down the expansion again.

(Refer Slide Time: 22:05)

$$\begin{aligned}
 &\rightarrow \tilde{x}(\tilde{t}) = \tilde{x}_0(\tilde{t}) + \epsilon \tilde{x}_1(\tilde{t}) + \epsilon^2 \tilde{x}_2(\tilde{t}) + \dots \\
 &\tilde{x}(0) = 0 \rightarrow \tilde{x}_0(0) + \epsilon \tilde{x}_1(0) + \epsilon^2 \tilde{x}_2(0) + \dots = 0 \\
 &\frac{d\tilde{x}}{d\tilde{t}}(0) = 1 \rightarrow \left\{ \begin{aligned} &\frac{d\tilde{x}_0}{d\tilde{t}}(0) + \epsilon \frac{d\tilde{x}_1}{d\tilde{t}}(0) + \epsilon^2 \frac{d\tilde{x}_2}{d\tilde{t}}(0) + \dots = 1 \end{aligned} \right\} \\
 &O(1): \quad \boxed{\tilde{x}_0(0) = 0 \quad \frac{d\tilde{x}_0}{d\tilde{t}}(0) - 1 = 0} \\
 &O(\epsilon): \quad \boxed{\tilde{x}_1(0) = 0 \quad \frac{d\tilde{x}_1}{d\tilde{t}}(0) = 0} \\
 &O(\epsilon^2): \quad \boxed{\tilde{x}_2(0) = 0 \quad \frac{d\tilde{x}_2}{d\tilde{t}}(0) = 0} \\
 &\text{L.H.S.} = \frac{d^2 \tilde{x}_0}{d\tilde{t}^2} + \epsilon \frac{d^2 \tilde{x}_1}{d\tilde{t}^2} + \epsilon^2 \frac{d^2 \tilde{x}_2}{d\tilde{t}^2} + \dots
 \end{aligned}$$

So, x of t tilde is x_0 tilde. This is my base state solution, I expect the base state solution to give me the lowest order approximation as ϵ goes to 0, the lowest order is just force is equal to constant. So, it should just tell me the $d^2 x_0$ by dt^2 is equal to minus 1 plus. Now, my initial condition is this.

So, what does it translate to? So, we will have to use this to obtain initial conditions for every order. So, how do we do this? So, we say $x_0 + \epsilon x_1 + \epsilon^2 x_2 + \dots = 0$. This is obtained by substituting the above into this equation. We also obtain this is x_0 at 0 equal to 1. I can satisfy the first equation by choosing, I am equating the coefficient of every power of ϵ to be 0. So, I will have and so on.

I have to for the second one I have to be a little bit more careful. I, there is an order one term here, this is an order ϵ , this is an order ϵ^2 . So, if I collect all the order one terms which are basically coefficients of ϵ to the power 0, then I get. So, so this is all let me write it at the same horizontal level.

So, this is order 1 – this and this. Then at order ϵ , we will have. Then at order ϵ^2 , we will have. And like before if I shift the one to the left hand side here, then I have 0 on the right hand side. So, I have to set all the coefficients to 0 in order to satisfy.

So, this, is my initial condition. These are my initial conditions at order 1. This is my initial condition at order ϵ . This is my initial condition at order ϵ^2 . So, you can see that we have 0 initial conditions at every order except 1, except at the lowest order. So, this will particularly simplify the algebra ok.

So, now what we have to do is, we have to go back and substitute this form into our governing differential equations. Let us do that. So, if I substitute, then the left hand side becomes the left hand side of my equation becomes $d^2 x_0 + \epsilon d^2 x_1 + \dots$ plus $\epsilon d^2 x_1 + \dots$.

(Refer Slide Time: 26:46)

$$\text{R.H.S.} = \frac{-1}{\left[1 + \epsilon(\tilde{x}_0 + \epsilon\tilde{x}_1 + \epsilon\tilde{x}_2 + \dots)\right]^2}$$

”Note the mistake: R.H.S = $\frac{-1}{[1 + \epsilon(\tilde{x}_0 + \epsilon\tilde{x}_1 + \epsilon^2\tilde{x}_2 + \dots)]^2}$.”

The right hand side has to be worked on. The right hand side is 1 plus x tilde whole square which is or epsilon x tilde whole square. So, this is epsilon into x naught tilde plus epsilon x 1. And now I will have to bring it up in the numerator using binomial expansion.

(Refer Slide Time: 27:16)

$$\begin{aligned}
 \text{R.H.S.} &= \frac{-1}{\left[1 + \varepsilon(\tilde{x}_0 + \varepsilon\tilde{x}_1 + \varepsilon\tilde{x}_2 + \dots)\right]^2} \\
 &= -\left[1 + \varepsilon(\dots)\right]^{-2} \\
 &= -\left[1 - 2\varepsilon(\tilde{x}_0 + \varepsilon\tilde{x}_1 + \varepsilon\tilde{x}_2 + \dots) \right. \\
 &\quad \left. + 3\varepsilon^2(\tilde{x}_0 + \varepsilon\tilde{x}_1 + \varepsilon\tilde{x}_2 + \dots) \dots \dots \right] \\
 \text{L.H.S.} &= \text{R.H.S.}
 \end{aligned}$$

So, this just becomes 1 plus epsilon the same thing to the power minus 2. And if you expand it, you are going to get. So, the power the exponent comes as a coefficient, then we just have this, then there will be more terms in the expansion. So, now, I have to set left hand side is equal to right hand side.

Collect all terms which are order 1 that will give me my equation governing x_0 tilde. Collect all terms order epsilon that will give me an equation governing x_1 tilde. In this equation, you will find that x_0 tilde appears on the right hand side. We cannot solve the order epsilon equation unless we have solve the order 1 equation. This is also true at every order. At every order, we can only solve it at that order provided we have solved at all previous orders.

In the next video, we will do this, we will continue this, we will write down the equations obtained at every order, pair them with the initial conditions that I wrote in the previous slide,

and then solve them individually. You will see that at every order, we will get a linear differential equation, but it will become inhomogeneous as we go to higher and higher orders, and that will give us once we solve those equations it we will recover our perturbative solution to the non-linear ordinary differential equation.
