**Lecture - 49**  
**Shape oscillations of a spherical interface (contd..)**

We were looking at perturbations of a interface which was spherical in the base state. In the base stage there was no velocity in the fluid inside as well as outside. The restoring force was purely due to surface tension we are ignoring gravity here and we have using variable separable solutions to the Laplace equation, we have guessed the form for the velocity potential the perturbation velocity potential in the fluid outside as well as inside, we also have guess the form for eta which is the perturbation at the surface.

$P_l(x) \rightarrow$  Legendre polynomials  
 $P_0(x) = 1 \quad -1 \leq x \leq +1$   
 $P_1(x) = x \quad x = \cos \theta$   
 $P_2(x) = \frac{1}{2}(3x^2 - 1)$   
 $\vdots$   
 $\downarrow$   
 $\phi_{out} = A x^{-(l+1)} P_l(\cos \theta) e^{i\omega t}$   
 $\phi_{in} = B x^l P_l(\cos \theta) e^{i\omega t}$   
 $\eta(\theta, t) = E P_l(\cos \theta) e^{i\omega t}$   
 $F(x, \theta, t) \equiv x - (R_0 + \eta(\theta, t))$   
 $\frac{DF}{Dt} = 0 \Rightarrow \frac{\partial F}{\partial t} + (\vec{u} \cdot \vec{\nabla}) F = 0 \quad \text{at } x = R_0 + \eta$

Diagrams: A coordinate system with  $x$  and  $\theta$  axes. A circle representing the interface at  $x = R_0 + \eta(\theta, t)$ . A small circle with a dot inside, labeled  $\downarrow \frac{1}{x} \frac{d}{dx} [x^2 \frac{dP_l(x)}{dx}]$ .

Now, using this we are going to conduct a normal mode analysis. Before we do that let us write down the boundary conditions. We have seen earlier that the kinematic boundary condition is expressed by DF by Dt the total derivative of a function F is equal to 0.

The function F is chosen in such a manner that its value is constant all over the surface. So, F in this case is going to be a function of r theta and t and this will be defined as r minus R 0 plus eta and eta itself is a function of theta comma t. You can see that the perturb interface is given by r is equal to R 0 plus eta.

Shape oscillations of drops & bubbles

Base-state: Interface  $\rightarrow$  Spherical of radius  $R_0$

Velocities  $\rightarrow 0$

$p_{in} - p_b^0 = \frac{2\gamma}{R_0}$   $\leftarrow$  Surface tension

Axisymmetric  $\rightarrow \frac{\partial}{\partial \varphi} \rightarrow 0$

$\nabla^2 \phi = 0$

$\Rightarrow \frac{1}{\lambda^2} \frac{\partial}{\partial \lambda} \left[ \lambda^2 \frac{\partial \phi}{\partial \lambda} \right] + \frac{1}{\lambda^2 \sin \theta} \frac{\partial}{\partial \theta} \left[ \sin \theta \frac{\partial \phi}{\partial \theta} \right] = 0$

$\Rightarrow \frac{\partial^2 \phi}{\partial \lambda^2} + \frac{2}{\lambda} \frac{\partial \phi}{\partial \lambda} + \frac{1}{\lambda^2} \cot \theta \frac{\partial \phi}{\partial \theta} + \frac{1}{\lambda^2} \frac{\partial^2 \phi}{\partial \theta^2} = 0$

$\phi = \Phi(\lambda) F(\theta) e^{i\omega t}$

NPTEL

Recall the picture that we had drawn earlier. So, any point on the interface is given by  $r$  is equal to the unperturbed radius plus some  $\eta$ . So, by definition capital  $F$  is 0 at the surface at the perturb surface. So, we have to. So, this is the kinematic boundary condition and we have to take the total derivative of  $F$  and equate it to 0. So, the total derivative is. So, we are continuing from here. So, this is  $\frac{dF}{dt} = \frac{\partial F}{\partial t} + \mathbf{u} \cdot \nabla F$ ; I will write it as  $\frac{d\phi}{dt}$  in the perturbation velocity potential and this is to be applied at  $r$  is equal to  $R_0$  plus  $\eta$ .

(Refer Slide Time: 02:27)

$$\begin{aligned}
 (\vec{u} \cdot \vec{\nabla}) F &= \left( \frac{\partial \phi}{\partial r} \right) \left( \frac{\partial F}{\partial r} \right) + \frac{1}{r^2} \left( \frac{\partial \phi}{\partial \theta} \right) \frac{\partial F}{\partial \theta} \\
 F &\equiv r - R_0 - \eta(\theta, t) \quad \text{Linearised analysis} \\
 \Rightarrow (\vec{u} \cdot \vec{\nabla}) F &= \left( \frac{\partial \phi}{\partial r} \right) 1 + \frac{1}{r^2} \left( \frac{\partial \phi}{\partial \theta} \right) \left( -\frac{\partial \eta}{\partial \theta} \right) \\
 &\quad \uparrow \quad \text{ignore} \\
 \frac{\partial F}{\partial t} + (\vec{u} \cdot \vec{\nabla}) F &= 0 \quad \text{at } r = R_0 + \eta \\
 \Rightarrow -\frac{\partial \eta}{\partial t} + \left( \frac{\partial \phi}{\partial r} \right) &= 0 \quad \text{at } r = R_0 + \eta \leftarrow \\
 &\quad \uparrow \\
 \Rightarrow \frac{\partial \eta}{\partial t} &= \left( \frac{\partial \phi}{\partial r} \right)_{r=R_0} \rightarrow \textcircled{1} \\
 &\quad \left( \frac{\partial \phi}{\partial r} \right)_{r=R_0+\eta} = \left( \frac{\partial \phi}{\partial r} \right)_{r=R_0} + \dots \quad \times
 \end{aligned}$$

So, let us work out the form for  $\vec{u} \cdot \nabla$  of  $F$  the second term in the total derivative operator. So, this in spherical axisymmetric coordinates would be  $\frac{\partial \phi}{\partial r}$  by  $\frac{\partial F}{\partial r}$  plus  $\frac{1}{r^2} \frac{\partial \phi}{\partial \theta}$  by  $\frac{\partial F}{\partial \theta}$ . Remember that  $F$  is defined as  $r$  minus  $R_0$  minus  $\eta$  which is a function of  $\theta$  and  $t$ .

So, I can write the right hand side of this expression as  $\vec{u} \cdot \nabla$  of  $F$  is equal to  $\frac{\partial \phi}{\partial r}$  by  $\frac{\partial F}{\partial r}$  and  $\frac{\partial F}{\partial r}$  is just 1 is just the derivative of small  $r$  with respect to itself plus  $\frac{1}{r^2} \frac{\partial \phi}{\partial \theta}$  by  $\frac{\partial F}{\partial \theta}$  will keep it that into  $\frac{\partial F}{\partial \theta}$  which is minus  $\frac{\partial \eta}{\partial \theta}$ .

Now, recall that we are going to do a linearised analysis, that is our first approximation  $\eta$  is the perturbation velocity potential  $\eta$  is the perturbation at the free surface. So, you can see that this is a product of two perturb quantities. So, this is going to be an order  $\epsilon^2$

term if you had non dimensionalized carefully and we had found the size of every term. So, this would have been if we had done the perturbation expansion this would have been an order epsilon term. So, I am going to ignore this term. So, ignore.

And so, now, our kinematic boundary condition was  $\frac{\partial F}{\partial t} + \mathbf{u} \cdot \nabla F$  is equal to 0. So, and this is at  $r$  is equal to  $R_0 + \eta$ . So,  $\frac{\partial F}{\partial t}$  is just minus  $\frac{\partial \eta}{\partial t}$  and  $\mathbf{u} \cdot \nabla F$  is just this term because we have ignored the second term. So, plus  $\frac{\partial \phi}{\partial r}$  equal to 0 at  $r$  equal to  $R_0 + \eta$ . Now this condition applies only to this derivative because  $\eta$  by definition does not depend on  $r$ . So, we do not have to worry about this condition on  $\frac{\partial \eta}{\partial t}$  only the second term is what we will have to worry about that where does this derivative get evaluated.

Like before you can see that  $\frac{\partial \phi}{\partial r}$  at  $r$  equal to  $R_0 + \eta$  may be written in a Taylor series as  $\frac{\partial \phi}{\partial r}$  at  $r$  equal to  $R_0$ . It is not 0 here its  $R_0$  because in the base state the drop or the bubble has a finite radius. So, this is  $\frac{\partial \phi}{\partial r}$  evaluated at the base state and then we are doing an expansion in  $r$ .

So, you will see that there will be a second term in the Taylor series. I leave it to you the second time will also be evaluated at  $r$  equal to  $R_0$ , but I leave it to you to convince yourself that the second term will be an order epsilon square term. It will be a non-linear term because it will involve derivative of  $\phi$  and then it will involve an  $\eta$ .

So, the product of those two is an order epsilon square term we are going to ignore this because this is a non-linear contribution. So, like before our kinematic boundary condition just reduces to  $\frac{\partial \eta}{\partial t}$  is equal to  $\frac{\partial \phi}{\partial r}$  evaluated at the unperturbed surface  $r$  equal to  $R_0$  let me call this some equation. So, I will call this may be equation 1 and then let us proceed from here.

(Refer Slide Time: 06:27)

$$\frac{\partial \eta}{\partial t} = \left( \frac{\partial \phi}{\partial r} \right)_{r=R_0}$$

LKBC:  $\frac{\partial \eta}{\partial t} = \left( \frac{\partial \phi^{in}}{\partial r} \right)_{r=R_0} = \left( \frac{\partial \phi^{out}}{\partial r} \right)_{r=R_0}$  (1a) & (1b)

PBC:  $(p^{in} - p^{out})_{r=R_0+\eta} = T (\nabla \cdot \hat{n})_{r=R_0+\eta} \rightarrow (2)$

$$\frac{p^{in}}{p^{in}} + \frac{\partial \phi^{in}}{\partial t} = C + \frac{2T}{R_0}$$

$$\frac{p^{out}}{p^{out}} + \frac{\partial \phi^{out}}{\partial t} = C$$

$$\frac{p_b^{in}}{p^{in}} + \frac{p_b^{out}}{p^{out}} + \frac{\partial \phi^{in}}{\partial t} = C + \frac{2T}{R_0}$$

$$\frac{p_b^{out}}{p^{out}} + \frac{\partial \phi^{out}}{\partial t} = C$$

$$\frac{p_b^{in}}{p^{in}} - \frac{p_b^{out}}{p^{out}} = \frac{2T}{R_0}$$

$$\frac{p_b^{in}}{p^{in}} = C + \frac{2T}{R_0}$$

$$\frac{p_b^{out}}{p^{out}} = C$$

So, now we have found that our kinematic boundary condition,  $\frac{\partial \eta}{\partial t}$  is  $\frac{\partial \phi}{\partial r}$  evaluated at  $r = R_0$ , but you see now we have two fluids in the inner fluid the velocity perturbation potential is  $\phi^{in}$  and in the outer fluid the velocity perturbation potential is  $\phi^{out}$ .

So, this derivative can be evaluated using either of those two potentials that derivative has to be evaluated if we come from the inner side, then it becomes  $\frac{\partial \phi^{in}}{\partial r}$  and if we come from the outer side approaching the interface then it becomes  $\frac{\partial \phi^{out}}{\partial r}$ . So, we expect that for this problem these two derivatives should be equal. It does not matter whether I use the inner fluid whether I approach from outwards or whether I approach from inwards, they should evaluate to the same value which is  $\frac{\partial \eta}{\partial t}$ .

So, you can see that the kinematic boundary condition now has two equations there are two equalities this and this. I am going to call this equation 1a and 1b, this is our linearized kinematic boundary condition. So, linearized kinematic boundary. So, that takes care of one boundary condition what about the other?

So, the other boundary condition is the pressure boundary condition. So, the pressure boundary condition which basically says that the difference between  $p$  in minus  $p$  out at  $r$  is equal to  $R_0$  plus  $\eta$  in the perturb state is  $T$  times the divergence of the unit normal and this divergence has to be evaluated at the perturb free surface we have seen this boundary condition before. Recall that  $p$  in and  $p$  out are the total pressure they are they can be written as a some of base perturbation.

So, let me call this maybe equation 2 and we also have the linearized Bernoulli equation. So, the linearized Bernoulli equation in this case is  $p$  in by  $\rho$  in plus  $\frac{1}{2} \frac{d\phi}{dt}$  in this is the unsteady Bernoulli equation linearize. So, I do not have the half  $\nabla \phi$  square term is equal to once again the Bernoulli constant is not zero here because in the base state there is a pressure jump across the interface.

So, if you evaluate this equation in the base state, it will just give you a pressure jump across the interface. So, I am just going to write it as some arbitrary constant plus twice  $T$  by  $R_0$  twice  $T$  by  $R_0$  is the magnitude of the pressure jump in the base state between  $p$  inside and  $p$  outside the difference between the two pressures.

I can write a similar equation for  $p$  out by  $\rho$  out plus  $\frac{1}{2} \frac{d\phi}{dt}$  out by  $\frac{d}{dt}$  is equal to  $C$ .  $C$  is just an arbitrary constant, it reflects the fact that only differences of pressure are known the absolute value is not known. So,  $C$  is an arbitrary constant and you will see that  $C$  will get eliminated in further in our analysis. So, the difference between these two is just twice  $T$  by  $R_0$  as we have seen when we wrote down the pressure difference in the base state. So, now, let us take this equation and work further on it.

So, I can write this equation as base plus perturbation the perturbation pressure is written in small small letters rho in plus for the velocity there is nothing more contribution from the wave base. So, the base is 0 and its just pure perturbation velocity potential. So, the same thing is equal to C plus twice T by R 0. Similarly, this equation gives us p b out by rho out plus small p out this is the perturbation pressure in the fluid outside by rho out plus del phi out by del t is equal to C.

You can see that I can cancel out the base state contribution we know that p b in minus p b out is equal to twice T by R 0. If I said p b in is equal to some constant plus twice T by R 0 as I have done here and p b out to be just the same constant C, then you can see that the difference between them satisfies this. So, I will cancel out the base state contribution. So, p b in and this and this are equal to each other.

(Refer Slide Time: 11:57)

$$\begin{aligned}
 \frac{p}{\rho} \Big|_{in} &= - \left( \frac{\partial \phi^{in}}{\partial t} \right) & \frac{p}{\rho} \Big|_{out} &= - \left( \frac{\partial \phi^{out}}{\partial t} \right) \rightarrow (3) \\
 (p^{in} - p^{out})_{\lambda=R_0+\eta} &= T (\nabla \cdot \hat{n})_{\lambda=R_0+\eta} \\
 \Rightarrow [p_b^{in} + p^{in} - p_b^{out} - p^{out}]_{\lambda=R_0+\eta} &= 0 \\
 \Rightarrow (p_b^{in} - p_b^{out})_{\lambda=R_0} + (p^{in} - p^{out})_{\lambda=R_0+\eta} &= T (\nabla \cdot \hat{n})_{\lambda=R_0+\eta} \rightarrow (4)
 \end{aligned}$$

R.H.S. of eqn (4)

$$\hat{n} = \nabla F = \left( \frac{\partial F}{\partial \lambda}, \frac{1}{\lambda} \frac{\partial F}{\partial \theta} \right) = \left( \underset{\uparrow \eta_\lambda}{1}, \underset{\uparrow \eta_\theta}{-\frac{1}{\lambda} \frac{\partial \eta}{\partial \theta}} \right)$$

$F \equiv \lambda - R_0 - \eta(\theta, t)$

Similarly, you can cancel out the base state contribution these two and so, we are left with two equations for perturbation pressure  $p$  in by  $\rho$  in is equal to minus  $\frac{\partial \phi}{\partial t}$  and  $p$  out by  $\rho$  out very similar minus  $\frac{\partial \phi}{\partial t}$  let us call this equation 3. So, now, we return to our boundary condition our boundary condition recall was  $p$  in minus  $p$  out the pressure boundary condition at  $r$  equal to  $R_0$  plus  $\eta$  is  $T$  times divergence of the unit normal evaluated at the perturbed interface.

I can split the pressures as a sum of base plus perturbation similarly base plus perturbation it will become this whole thing evaluated at  $r$  equal to  $R_0$  plus  $\eta$  is equal to the right hand side. I can write this further as  $p_b$  in minus  $p_b$  out in the base state  $r$  is just equal to capital  $R$  naught. So, this is just capital  $R$  naught plus  $p$  in minus  $p$  out evaluated at  $R$  naught plus  $\eta$  is equal to  $t$  of divergence of  $n$  at  $R$  naught plus  $\eta$  there is no hat I will call this equation, equation 4.

Let us work on the right hand side of equation 4. So, right hand side of equation 4 for the right hand side we will need an expression for  $n$ , we have seen that  $n$  is evaluated in the linearized approximation as just  $\text{grad } F$  it is actually  $\text{grad } F$  divided by mod of the same thing the mod actually is a non-linear contribution. So, the denominator is just 1 at linear order. So, this in spherical coordinates is just  $\frac{\partial F}{\partial r}$  into  $\frac{1}{r}$  by  $\frac{\partial F}{\partial \theta}$  we are not writing the  $\psi$  component because this is axisymmetry.

So, that is the  $r$  component of  $n$  radial component and that is the  $\theta$  component of  $n$ .  $F$  is defined as  $r$  minus  $R$  naught minus  $\eta$  and  $\eta$  itself is a function of  $\theta$  and  $t$ . So, I can work on this and I can write it as 1 it is just  $\frac{\partial r}{\partial r}$  and then this is minus  $\frac{1}{r}$   $\frac{\partial \eta}{\partial \theta}$  that is  $n$ . Once again recall that this is the  $r$  component or the radial component and this is the  $\theta$  component of  $n$ . We need the divergence of the unit normal in equation 4, right hand side.

(Refer Slide Time: 15:06)

$$\begin{aligned}
 \nabla \cdot \hat{n} &= \frac{1}{r^2} \frac{\partial}{\partial r} (r^2 n_r) + \frac{1}{r \sin \theta} \frac{\partial}{\partial \theta} (n_\theta \sin \theta) \\
 n_r &= 1, \quad n_\theta = -\frac{1}{r} \frac{\partial \eta}{\partial \theta} \\
 &= \frac{1}{r^2} 2r - \frac{1}{r^2 \sin \theta} \frac{\partial}{\partial \theta} \left[ \sin \theta \frac{\partial \eta}{\partial \theta} \right] \quad \frac{2}{R_0 \left(1 + \frac{\eta}{R_0}\right)} \\
 &= \frac{2}{r} - \frac{1}{r^2} \cot \theta \frac{\partial \eta}{\partial \theta} - \frac{1}{r^2} \frac{\partial^2 \eta}{\partial \theta^2} \\
 (\nabla \cdot \hat{n})_{r=R_0+\eta} &= \frac{2}{R_0+\eta} - \frac{1}{(R_0+\eta)^2} \cot \theta \frac{\partial \eta}{\partial \theta} - \frac{1}{(R_0+\eta)^2} \frac{\partial^2 \eta}{\partial \theta^2} \\
 &\approx \frac{2}{R_0} \left(1 - \frac{\eta}{R_0}\right) - \frac{1}{R_0^2} \cot \theta \frac{\partial \eta}{\partial \theta} - \frac{1}{R_0^2} \frac{\partial^2 \eta}{\partial \theta^2}
 \end{aligned}$$

Let us compute the divergence. So, the divergence of  $\mathbf{n}$  is given in spherical coordinates by the following expression  $\frac{1}{r^2} \frac{\partial}{\partial r} (r^2 n_r) + \frac{1}{r \sin \theta} \frac{\partial}{\partial \theta} (n_\theta \sin \theta)$ . Once again this is a standard formula you can look it up in any book on transport phenomena.

Now, we have seen that the radial component of  $\mathbf{n}$  is 1, the theta component of  $\mathbf{n}$  is  $-\frac{1}{r} \frac{\partial \eta}{\partial \theta}$ . If I substitute it in the expression above then I obtain  $\frac{1}{r^2} \frac{\partial}{\partial r} (r^2 n_r)$  because  $n_r$  is 1. So, that will just give me a  $\frac{2}{r}$  and then I will have minus because there is a minus in  $n_\theta$  the expression for  $n_\theta$  contains a minus sign.

So, I pull that out outside and I write this as  $-\frac{1}{r \sin \theta} \frac{\partial}{\partial \theta} (n_\theta \sin \theta)$ . So, this can be simplified to  $\frac{2}{r} - \frac{1}{r^2} \cot \theta \frac{\partial \eta}{\partial \theta} - \frac{1}{r^2} \frac{\partial^2 \eta}{\partial \theta^2}$ .

square cot theta, I am carrying out the derivative inside and so, this just becomes cot theta into  $\frac{\partial \eta}{\partial \theta} \frac{1}{r^2} \frac{\partial^2 \eta}{\partial \theta^2}$ .

The expression for divergence of  $\mathbf{n}$  is slightly more complicated as the geometry becomes curvilinear we have seen such expressions even in cylindrical coordinates. It was the simplest in Cartesian coordinates where we just had one term at linear order. Now, recall that this expression has to be evaluated at  $r$  equal to  $R_0 + \eta$ . So, at  $r$  equal to  $R_0 + \eta$  and we have to linearize, we have to retain only terms which are linear in  $\eta$ .

So, this just becomes  $\frac{1}{R_0 + \eta} \frac{\partial \eta}{\partial \theta} \frac{1}{(R_0 + \eta)^2} \frac{\partial^2 \eta}{\partial \theta^2}$ . Let us linearize and retain only term which are linear in  $\eta$  you can see that the first term. So, I can write this as. So, I can write the first term here as  $\frac{2}{R_0} \frac{\partial \eta}{\partial \theta} \frac{1}{R_0} \frac{\partial^2 \eta}{\partial \theta^2}$ .  $\eta$  is a small quantity because I am going to set  $\eta$  equal to some surface deformation and that is a order epsilon quantity.

I can use binomial theorem to take it to the top and then this just becomes  $\frac{2}{R_0} \frac{\partial \eta}{\partial \theta} \frac{1}{R_0} \frac{\partial^2 \eta}{\partial \theta^2}$ . You can see that in the second term if I do the same and if I want to retain only up to order  $\eta$  not beyond that I do not want anything which is order  $\eta^2$   $\eta^3$  and so, on then this term will be evaluated just at in the denominator we just have to keep  $R_0^2$ .

There will be no further contribution and it will just become cot theta into  $\frac{\partial \eta}{\partial \theta}$ . Similarly, this one will become  $\frac{1}{R_0^2} \frac{\partial^2 \eta}{\partial \theta^2}$ . I encourage you to try doing an expansion and convincing yourself that this is what we would obtain at if we retain terms only up to order  $\eta$ . Now you can see that all the terms here have an  $\eta$  in them except in the first term.

So, this is the term which basically comes from the base state and it will get cancelled out let us see how. So, we go back to our equation that we had written equation 4. So, now, we have worked on the right hand side of equation 4, we already have the expression for the right hand

side. So, we will use the previous equations to obtain an expression for the base state pressure and the perturbation pressure and we will write down a final equation.

(Refer Slide Time: 19:44)

$$\begin{aligned}
 & (\cancel{p_b^{\text{in}}} - \cancel{p_b^{\text{out}}})_{\lambda=R_0} + (p_b^{\text{in}} - p_b^{\text{out}})_{\lambda=R_0+\eta} \\
 & = T \left[ \cancel{\frac{2}{R_0}} \left( \cancel{\frac{\eta}{R_0}} \right) - \frac{1}{R_0^2} \cot \theta \frac{\partial \eta}{\partial \theta} - \frac{1}{R_0^2} \frac{\partial^2 \eta}{\partial \theta^2} \right] \\
 & p_b^{\text{in}} - p_b^{\text{out}} = \frac{2T}{R_0} \\
 & (p_b^{\text{in}} - p_b^{\text{out}})_{\lambda=R_0+\eta} = -T \left[ \frac{2\eta}{R_0^2} + \frac{1}{R_0^2} \cot \theta \frac{\partial \eta}{\partial \theta} + \frac{1}{R_0^2} \frac{\partial^2 \eta}{\partial \theta^2} \right] \\
 & \Rightarrow p_b^{\text{out}} \left( \frac{\partial p_b^{\text{out}}}{\partial t} \right)_{\lambda=R_0} - p_b^{\text{in}} \left( \frac{\partial p_b^{\text{in}}}{\partial t} \right)_{\lambda=R_0} \\
 & = -\frac{T}{R_0^2} \left[ 2\eta + \cot \theta \frac{\partial \eta}{\partial \theta} + \frac{\partial^2 \eta}{\partial \theta^2} \right] \rightarrow \textcircled{5}
 \end{aligned}$$

So, we go back to equation 4 now. So, equation 4 is basically  $p_b^{\text{in}} - p_b^{\text{out}}$  and this is not really a function of  $r$ , but I will still write it at  $r$  equal to  $R_0$  because in the base state the pressure is uniform inside as well as outside.  $p_b^{\text{in}} - p_b^{\text{out}}$  at  $r$  is equal to  $R_0$  plus  $\eta$  is equal to  $t$  times divergence of  $n$  evaluated at  $r$  equal to  $R_0$  plus  $\eta$  and we have worked that out up to linear order in  $\eta$ .

So, up to linear order in  $\eta$  it is just  $t$  into  $2$  by  $R_0$  into  $1$  minus  $\eta$  by  $R_0$  that is the first term then we will get  $1$  minus  $1$  by  $R_0^2$   $\cot \theta \frac{\partial \eta}{\partial \theta}$  minus  $1$  by  $R_0^2$   $\frac{\partial^2 \eta}{\partial \theta^2}$ . We have already seen that the base state pressure satisfies the relation  $p_b^{\text{in}} - p_b^{\text{out}}$  these are uniform pressures is

equal to twice  $T$  by  $R_0$ . You can see that I can cancel out I can use that equation to cancel out this term with the first term. So, the first term if you open the bracket will be twice  $T$  by  $R_0$ .

So, I can cancel that out that is a base state contribution. So, we are left with just the perturbation pressures which in general has to be evaluated at  $R_0 + \eta$ , but we will soon argue that using Taylor series that these perturbation pressures have to be evaluated at capital  $R_0$  and not  $R_0 + \eta$  ok.

But let us come to that later. So, you can see that in all the three terms. So, this is one term, this is another term and this is another term all of them have a minus sign. So, I can pull the minus sign outside and then write this as twice  $\eta$  by  $R_0^2$  plus 1 by  $R_0^2$  square  $\cot \theta$   $\frac{\partial \eta}{\partial \theta}$  plus 1 by  $R_0^2$  square  $\frac{\partial^2 \eta}{\partial \theta^2}$ .

Now, we have to use our expressions for perturbation pressure. In our earlier equation we have already obtained in equation 3. Equation 3 there are two equations at the top of this slide there is two expressions for the perturbation pressure inside and outside. We need the difference of them if we take the difference then we can using these expressions we can substitute and find that the left hand side of the above.

So, I am just coming from here the expression for  $p_{in}$  and  $p_{out}$  is already available before. So, if I use those expressions and take the difference then it just turns out to be  $\rho_{out} \frac{\partial \phi_{out}}{\partial t}$ . And now you can see where this derivative should be evaluated  $\phi$  itself is a perturbation velocity potential if you expand it in Taylor series the first term will be evaluated at  $R_0$ , but the next term will have a derivative of  $\frac{\partial \phi}{\partial t}$  with respect to  $r$  and then an  $\eta$ ,  $\eta$  itself is a order epsilon quantity  $\phi$  itself is an order epsilon quantity.

So, the product will be an order epsilon square quantity. So, we will not written it and so, just the first term is enough. And similarly for the other term it will be  $\rho_{in}$  note that for pressure it was  $p_{in} - p_{out}$  for velocity potentials it will become  $\phi_{out} - \phi_{in}$  that is

because there is a minus sign in the expressions for pressure. So, in equation 3 you can see that  $p_{in}$  and  $p_{out}$  both have a minus sign on the right hand side.

So, that causes a flip. So,  $-\rho_{in} \frac{d\phi_{in}}{dt}$  at  $r$  is equal to  $R_0$  is equal to  $I$  can take the  $R_0$  square out and just write it as  $2\eta + \cot\theta \frac{d\eta}{d\theta} + \frac{d^2\eta}{d\theta^2}$  let us call this equation 5. So, I have now two equations one comes from the kinematic boundary condition which we have already written earlier.

So, we have already written equation 1 a and 1 b and there are two equations here from the kinematic boundary condition this is because we are now dealing with two fluids both inside as well as outside. In all the previous examples we have taken only one fluid this is the first example where we are considering both the fluids. So, the kinematic boundary condition gives us two equations this is two equations and then there is a pressure equation which comes from the pressure boundary condition equation 5.

(Refer Slide Time: 25:06)

$$\left. \begin{aligned} \phi^{out} &= A r^{-(l+1)} P_l(\cos \theta) e^{i\omega t} \\ \phi^{in} &= B r^l P_l(\cos \theta) e^{i\omega t} \\ \eta &= E P_l(\cos \theta) e^{i\omega t} \end{aligned} \right\} \text{Normal modes}$$

$$\frac{\partial \eta}{\partial t} = \left( \frac{\partial \phi^{in}}{\partial r} \right)_{r=R_0} = \left( \frac{\partial \phi^{out}}{\partial r} \right)_{r=R_0}$$

$$\uparrow$$

$$i\omega E P_l(\cos \theta) e^{i\omega t} = l B R_0^{l-1} P_l(\cos \theta) e^{i\omega t}$$

$$\Rightarrow i\omega E - l B R_0^{l-1} = 0$$

Note the error:  $i\omega E - l B R_0^{l-1} = 0$

Let us use these two equations and so, recall. So, we had set phi out to be A r to the power minus l plus 1 P l of cos theta e to the power i omega t. Note that I have again gone back to theta we had called x is equal to cos theta, but now I have gone back to theta using theta is the independent variable.

So, then phi in is equal to some complex constant B into r to the power l p l of cos theta e to the power i omega t and eta was some complex constant into P l of cos theta e to the power i omega t this was our normal modes. We have to plug in these forms into our three equations 2 of these equations will come from the kinematic boundary condition and the third one will be the pressure condition which we have just derived. So, let us do that.

So, recall that our kinematic boundary condition which we have already written linearized kinematic boundary condition is just this evaluated at R naught. If I use this equality and

equate the first two and use these expressions, then you can see that I get the expression for  $\eta$  I get  $i\omega E P_l$  of  $\cos\theta$  will indicate that as a dot into  $e$  to the power  $i\omega t$  is equal to  $\frac{d\phi}{dr}$ . So, that will bring out  $l$  and then this will be  $B$  and then it will be  $r$  to the power  $l-1$ , but small  $r$  is  $r_0$ .

So, I will make it  $R_0$  to the power  $l-1$ . And then again  $P_l$  of  $\cos\theta$  represent it as a dot  $e$  to the power  $i\omega t$ . These two are not 0 in general and so, I can equate this and I can get one equation which is this. Note that we need three equations because there are now three constants  $A$ ,  $B$  and  $E$ .  $A$ ,  $B$  and  $E$ . So, we expect to get three equations three homogeneous equations in these three unknowns and the determinant of the coefficient matrix will give us the dispersion relation.
