Feedback Control Schemes (Contd.)

(Refer Slide Time: 01:00)

In the last class, we discuss Cohen coon technique. We discussed the algorithm on Cohen coon method. So, today we will solve one problem based Cohen coon technique I mean we will determine the tunic parameter values of the controller using this technique. The close loop black diagram is given with the transfer function of controller as G_c equals $k_c \left(1 + \frac{1}{\tau_i s} + \tau_d s \right)$ this is the transfer function of PID controller, then as we discussed the final control eliminate and controller blocker disconnected.

So, that is 1 here, then the final control eliminate output goes to the process, having the transfer function G_p equals $\frac{1}{(s+3)^2}$. This is the transfer function of the process. Output of this block is \bar{y} , then this output is measured, the measured signal is then compared with set point of value, so this is basically not the close loop black diagram, we have disconnected here. Suppose, a units step change is

introduced in the controller output signal, input a unit step change introduced in input signal to the final control eliminate.

So, this is the process, first we need to form the transfer function of the process reaction curve. So, transfer function Process Reaction Curve of PRC is equal to y_m bar divided by c bar, which is equal to $G_p G_f G_m$ for simplicity we have consider G_m equals 1 similarly, we will consider G_f equals 1. Now, if we substitute individual the transfer functions $G_p G_f G_m$ then we get GPRC equals 1 divided by s plus 3 whole square. So, this is the transfer function of the system example system, as mentioned that unit step change introduced in the input signal to the final control element.

So, the process this transfer function becomes, not transfer function this output becomes 1 divided by s plus 3 whole square, when c bar s equals 1 by s we are just substitute c bar s equals 1 by s in this process reaction curve. Now, we basically need the y_m in the time domain so, for that we need to expand into partial reactions.

(Refer Slide Time: 07:05)

Handwritten mathematical derivation on a blue background:

$$\frac{1}{s(s+3)^2} = \frac{A_1}{s+3} + \frac{A_2}{(s+3)^2} + \frac{B_1}{s}$$

$$A_1 = -\frac{1}{9}$$

$$A_2 = -\frac{1}{3}$$

$$B_1 = \frac{1}{9}$$

$$\bar{y}_m(s) = -\frac{1}{9(s+3)} - \frac{1}{3(s+3)^2} + \frac{1}{9s}$$

$$y_m(t) = -\frac{1}{9} \cdot e^{-3t} - \frac{1}{3} \cdot t e^{-3t} + \frac{1}{9}$$

$$\dot{y}_m = t e^{-3t} \quad \dots \text{first derivative}$$

$$\ddot{y}_m = e^{-3t} (1-3t) \quad \dots \text{second derivative}$$

I mean we can write this as A_1 divided by s plus 3 plus A_2 divided by s plus 3 whole square plus B_1 divided by s in the next we need to determine the values of this coefficient say A_1 , A_2 and B_1 . So, finally, we will get this form y_m bar s equals minus 1 divided by 9 s plus 3 minus 1 divided by 3 s plus 3 whole square plus 1 divided by 9 s . That means we got A_1 equals minus 1 by 9 similarly, A_2 equals minus 1 3rd and B_1 equals 1 by 9. So, the determination of that is coefficient is left for you.

So, this is the ultimate form of y_m . Next we take the inverse of Laplace transform, take the inverse of Laplace transform. If we take the inverse of Laplace transform then we get y_m in time domain as $y_m(t)$ equals $\frac{1}{9} e^{-3t} - \frac{1}{9} e^{-3t} + \frac{1}{9} e^{-3t}$. So, this is the expression of y_m in time domain, in the next step we need to determine the first derivative and second derivative of y_m , find the first and second derivative of y_m .

The first derivative of y_m represented by \dot{y}_m equals $t e^{-3t}$. Check this, first derivative of y_m we get as $t e^{-3t}$, this is the first derivative. Now, second derivative we obtain as \ddot{y}_m here, approximate use $2 \dot{y}_m$ exponential of $-3t - 1 - 3t$ this is the second derivative.

(Refer Slide Time: 11:32)

\checkmark Location of the inflection point is obtained $\ddot{y}_m = 0$.
 $t = \frac{1}{3}$ point of inflection occurs at $t = \frac{1}{3}$.
 \checkmark Slope of the tangent line through this point is
 $s = \dot{y}_m(t = \frac{1}{3}) = t \cdot e^{-3t} = \frac{1}{3} \cdot e^{-1} = 0.123$.

In the location of the inflection point obtain by setting the second derivative equals 0. So, if we do that, then we get t equals $\frac{1}{3}$, this is the route of interest in this problem t equals $\frac{1}{3}$. So, the point of inflection of occurs at t equals $\frac{1}{3}$. In the next we will determine the slope of the tangent line, the slope of the tangent line through this point is s equals first derivative at t equals $\frac{1}{3}$ find the value, the expression is $t e^{-3t}$, if we substitute t equals $\frac{1}{3}$ then we obtain 0.123. The slope we obtain 0.123 I think at this stage, it is good through drawer response.

(Refer Slide Time: 14:05)

This is time and this is $y_m t$. So, at this point t equals $1/3$ 'rd, this point is correspond to equal $1/3$ 'rd means this is the point of inflection. Now, this point represents the debt time. Now, the slope we obtain 0.123 . So, this is the process reaction curve, can you find the corresponding y_m value at t equals $1/3$ 'rd, find the corresponding y_m value at t equals $1/3$ 'rd.

(Refer Slide Time: 16:17)

✓ Location of the inflection point is obtained $\ddot{y}_m = 0$. SCET
I.T.KGP

$$t = \frac{1}{3} \quad \text{point of inflection occurs at } t = \frac{1}{3}.$$

✓ Slope of the tangent line through this point is

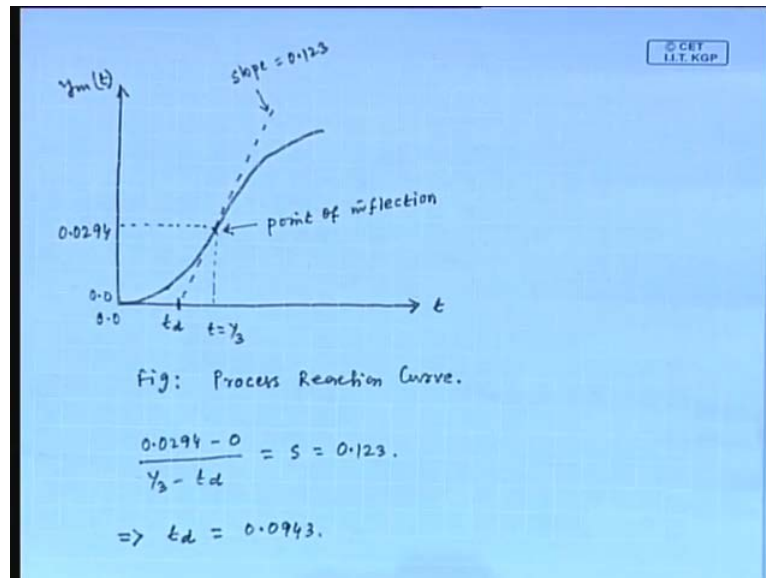

$$S = \dot{y}_m(t = \frac{1}{3}) = t \cdot e^{-2t} = \frac{1}{3} \cdot e^{-1} = 0.123.$$

$$\ddot{y}_m = -\frac{1}{9} e^{-2t} - \frac{1}{3} t e^{-2t} + \frac{1}{9}$$

$$= e^{-1} \left(-\frac{2}{9}\right) + \frac{1}{9} = 0.0294$$

We have the expression for y_m that is $1 - 9 \exp(-3t) - 1/3 \exp(-3t)$. If we substitute $t = 1/3$, we obtain this, which is equal to 0.0294. So, the y_m at $t = 1/3$ we obtain 0.0294.

(Refer Slide Time: 17:16)

So, this is 0.0294. Now, it is obvious from this plot that $0.0294 - 0$ divided by $1/3 - t_d$ equals what slope, it is obvious from this figure that this equals slope, a slope is how much 0.123 from this correlation we can determine the value of their time, from this correlation we can determine the value of dead time, how much is that 0.0943. So, we obtain the dead time 0.0943 can you determine the ultimate value of y_m .

(Refer Slide Time: 18:50)

$B = \text{ultimate value of } y_m(t) = \lim_{t \rightarrow \infty} y_m(t) = \frac{1}{9}$
 $k = \frac{B}{A} = \frac{Y_9}{1} = \frac{1}{9}$
 $\tau = \frac{B}{s} = \frac{Y_9}{0.123} = 0.9033$
PID:
 $k_c = \frac{1}{k} \frac{\tau}{t_d} \left(\frac{4}{3} + \frac{t_d}{4\tau} \right) = 117.2$
 $\tau_i = t_d \frac{32 + 6t_d/\tau}{13 + 8t_d/\tau} = 0.222$
 $\tau_D = t_d \frac{4}{11 + 2t_d/\tau} = 0.0336$

We represent the ultimate value of y_m by B . So, B equals how much you calculate ultimate value of y_m that is limit t tense to infinity y_m t equals 1 by 9. Now, we determine they gain k , we determine the gain k , k equals to B divided by A , B this is the ultimate value of the response and A is the magnitude of input function.

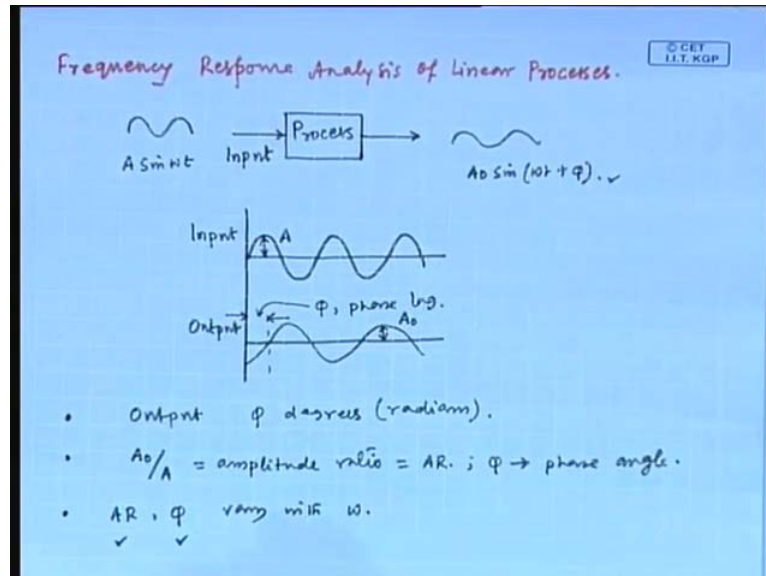

So, B we obtain 1 by 9 and A is 1 because we have introduced in needs to change; that means, k is 1 by 9. Next we need to determine the time constant τ , which is represented by B by s . Now, B will obtained 1 by 9 and rates is 0.123. So, it gives 0.9033. So, τ is 0.9033 in Cohen coon method basically response of chemical processes is subjected to step input can be approximated by the response of first order plus get time system. So, accordingly we have determine the k τ and t_d .

Now, what controller we have used PID controller, they have proposed the expression for k_c τ_i and τ_D , as the function of this k τ and t_d like for PID controller the expression for k_c is represented as k_c equals 1 by k τ by t_d multiplied by 4 by 3 plus t_d divided by 4 τ . So, we know the values of τ t_d and k substituting those values, we obtain k_c equals 117.2 substituting the values of k τ and t_d obtain k_c equals 117.2.

Similarly, the expression for τ_i as the form τ_i equals t_d 32 plus 6 t_d by τ divided by 13 plus 8 t_d by τ which is equals to 0.222 and the derivative time which is equal to t_d 4 divided by 11 plus 2 t_d by τ and we can calculate this τ_D equals 0.0336 by this

way we can tune the controller, using the Cohen-coon technique. Next we will discuss the frequency response analysis of linier systems.

(Refer Slide Time: 24:10)

Our next topic is, frequency response analysis of linier processes. So, we need to consider the linier process and the linier process is substituted to a sinusoidal input, this it is ultimate response, after a long time is also a substantial sinusoidal wave, it can be prove that, a linier system a subjected to a sinusoidal input. It is ultimate response after a long time is also a substantial sinusoidal wave $A_0 \sin(\omega t + \phi)$ of amplitude, ω is the frequency and ϕ is the phase leg.

So, this is the input which has the amplitude A , this is the output which has the amplitude A_0 and this output is out of phase by ϕ degrees or radian, this is representing ϕ , phase leg, these are 2 o f's. Now, it is obvious that both inputs and outputs are sinusoidal and the output is out of phase by ϕ degrees or radians. The ratio of output and input amplitudes, is known as amplitude ratio enamel A_0/A is represented by AR , which is amplitude ratio and ϕ is call the phase angle.

Now, this amplitude ratio and ϕ both vary with ω , how the amplitude ratio an ϕ vary with ω is the main concern of frequency response analysis, amplitude ratio and ϕ values vary with ω . Now, how the amplitude ratio an ϕ , vary with ω is the main concern of frequency response analysis. Now, we discuss the fundamental frequency response result.

(Refer Slide Time: 29:54)

Fundamental.

$Z = a + jb$

$|z| = \sqrt{a^2 + b^2}$

$\arg(z) = \angle z = \tan^{-1} \frac{b}{a}$

$G(s) \Big|_{s=j\omega} = G(j\omega) = \text{Frequency-response transfer function.}$

$AR = |G(j\omega)|$

$\phi = \arg[G(j\omega)] \text{ or } \angle G(j\omega)$

The fundamental frequency response result. A complex number denoted by z whose real part is a and imaginary part is b , can be expressed as z equals a plus j b , j b is the complex number. Now, in the complex plane we will locate the z . So, this is the real part a and this is the imaginary part b . Now, the magnitude of z , we can find as magnitude of z equals root over of a square plus b square and argument of z which we can write by this and it can be determined using this form, I mean argument z equals \tan inverse b by a .

This is the argument z . Now, for a particular process we usually have the transfer function G s . Now, if we substitute s equals j ω , then we get frequency response transfer function replacing s by j ω , we obtain frequency response transfer function. Now, amplitude ratio we can determine I mean the amplitude ratio is the magnitude of this G j ω , amplitude ratio is the magnitude of the frequency response transfer function. Similarly, the phase angle ϕ is the argument of this frequency response transfer function, it can be represented by this notation.

So, this is the fundamental of frequency response result. Next, we discuss the general procedure for frequency response for finding the response frequency.

(Refer Slide Time: 34:17)

General Procedure

$\bar{u}(s) \rightarrow G(s) \rightarrow \bar{y}(s)$

Step-1: $G(s) \Big|_{s=j\omega} = G(j\omega)$ ✓

Step-2: Represent $G(j\omega)$ in the Cartesian form:
 $G(j\omega) = \text{Re}(\omega) + j \cdot \text{Im}(\omega)$ ✓

Step-3: $AR = \sqrt{[\text{Re}(\omega)]^2 + [\text{Im}(\omega)]^2}$ ✓
 $\phi = \tan^{-1} \left(\frac{\text{Im}(\omega)}{\text{Re}(\omega)} \right)$ ✓

General procedure for finding the frequency response. First we discuss generalizing then we will take few examples to finding the frequency response are to analyze the frequency response, say $G(s)$ is the transfer function of a process. Now, input to this process we can write as $\bar{u}(s)$ and output is $\bar{y}(s)$ in the first step, we need to replace s by $j\omega$ in the first step we should replace s by $j\omega$ to obtain the frequency response transfer function, this is step one, substitute $s = j\omega$ and find the frequency response transfer function.

In the next step represent this frequency response transfer function in Cartesian form; that means, $G(j\omega) = \text{Re}(\omega) + j \cdot \text{Im}(\omega)$. Now, this way we can clearly identify the real part and imaginary part, this is step 2. In step 3 we can determine the amplitude ratio and phase angle, we know amplitude ratio equals root over of square of this real part plus square of this imaginary part. We can determine the amplitude ratio using this similarly, the phase and here we can determine from this have $\phi = \tan^{-1} \left(\frac{\text{Im}(\omega)}{\text{Re}(\omega)} \right)$.

So, we just substitute $s = j\omega$ to get the frequency response transfer function, then represent that frequency response transfer function in this form I mean just you try to find out the real and imaginary part, after doing that use these 2 expressions to obtain amplitude ratio and phase angle. Now, the alternative technique in the alternative technique we can represent the frequency response transfer function in polar form.

(Refer Slide Time: 38:49)

The image shows a handwritten derivation on a blue background. At the top right, there is a small logo for '© CEF I.I.T. KGP'. The derivation starts with the polar form: $G(j\omega) = AR \cdot e^{j\phi}$, with a note '---- polar form.'. Below this, the transfer function is expressed as a ratio of magnitudes and exponential terms: $G(j\omega) = \frac{N(j\omega)}{D(j\omega)} = \frac{|N(j\omega)| e^{jL_N(j\omega)}}{|D(j\omega)| e^{jL_D(j\omega)}}$. This is then simplified to $= \frac{|N(j\omega)|}{|D(j\omega)|} e^{jL_N(j\omega) - jL_D(j\omega)}$, which is equated to $= AR \cdot e^{j\phi}$. A bracket under the exponent indicates that $\phi = L_N(j\omega) - L_D(j\omega)$. Finally, the amplitude ratio is defined as $AR = \frac{|N(j\omega)|}{|D(j\omega)|}$.

So, we can represent the frequency response transfer function in polar form, amplitude ratio exponential of $j\phi$. Now, we can write this frequency response transfer function as $j\omega$ equals the numerator divided by the denominator part. Now, we will apply the polar form I mean we can write the numerator as amplitude and then the exponential term. Similarly, we can write the denominator as first tau a magnitude of the denominator multiplied by the exponential term, this is amplitude, this is magnitude of this numerator multiplied by this exponential term.

Similarly, for the denominator this is the magnitude of the denominator D and this is the exponential term. Now, this we can write again as numerator magnitude divided by denominator magnitude, exponential j in $j\omega$ minus $j d j\omega$, the polar form of the frequency response transfer function we have written here amplitude ratio exponential of $j\phi$. Now, we will compare this 2, then we obtained the expression for amplitude ratio as, amplitude ratio equals this, the magnitude of N numerator divided by the magnitude of denominator and we obtained the expression for ϕ also.

So, we can determine the amplitude ratio ϕ by this way also, here the steps are substitute s equals $j\omega$ to obtain the frequency response transfer function, then you represent the frequency response transfer function by this form, this numerator by denominator, then use this 2 expression to determine the amplitude ratio and ϕ . So, we

will take one example to find the frequency response I mean to discuss the frequency response analysis.

(Refer Slide Time: 42:54)

First-order system

$$G(s) = \frac{K}{\tau s + 1}$$

step-1 $s = j\omega$

$$G(j\omega) = K \left(\frac{1}{1 + j\tau\omega} \right) = K \left(\frac{1}{1 + j\tau\omega} \right) \cdot \frac{1 - j\tau\omega}{1 - j\tau\omega}$$

$$G(j\omega) = K \frac{1 - j\tau\omega}{1 + \tau^2\omega^2}$$

step-2 In Cartesian form:

$$G(j\omega) = K \left[\frac{1}{1 + \tau^2\omega^2} - j \frac{\tau\omega}{1 + \tau^2\omega^2} \right] = \text{Re}(\omega) + j \text{Im}(\omega)$$

$$\text{Re}(\omega) = K \left(\frac{1}{1 + \tau^2\omega^2} \right) \quad ; \quad \text{Im}(\omega) = -K \left(\frac{\tau\omega}{1 + \tau^2\omega^2} \right)$$

step-3

$$AR = \sqrt{[\text{Re}(\omega)]^2 + [\text{Im}(\omega)]^2} = \frac{K}{\sqrt{1 + \tau^2\omega^2}}$$

So, we will consider is first order processes, first order system. The transfer function of a first order system suppose, is given as $G(s) = \frac{k}{\tau s + 1}$, k is the steady state gain of the first order system and τ is the time constant. Now, we proceed step by step, in the first step we need to replace s by $j\omega$. So, you substitute $s = j\omega$, then we can write $G(j\omega) = \frac{k}{1 + j\tau\omega}$.

So, we can write this again as k multiplied by $\frac{1}{1 + j\tau\omega} \cdot \frac{1 - j\tau\omega}{1 - j\tau\omega}$, can we write this. So, this is equal to $k \frac{1 - j\tau\omega}{1 + \tau^2\omega^2}$. After substitute $s = j\omega$ we obtain this form. Now, we need to represent this frequency response transfer function Cartesian form that is step 2. In Cartesian form we can write the frequency response transfer function has $G(j\omega) = \frac{k}{1 + \tau^2\omega^2} - j \frac{\tau\omega}{1 + \tau^2\omega^2}$, we can write this from this expression.

Now, we need to find the real part and imaginary part. So, if you compare this with this, we obtained the real part s , this real part equal k divided by $1 + \tau^2\omega^2$ and comparing this 2 again we get the imaginary part also. Imaginary part is equal to $-k \tau\omega$ divided by $1 + \tau^2\omega^2$. So, you obtain in step

2 the real part and imaginary part. In step 3 we will determine the amplitude ratio and phi using the expressions.

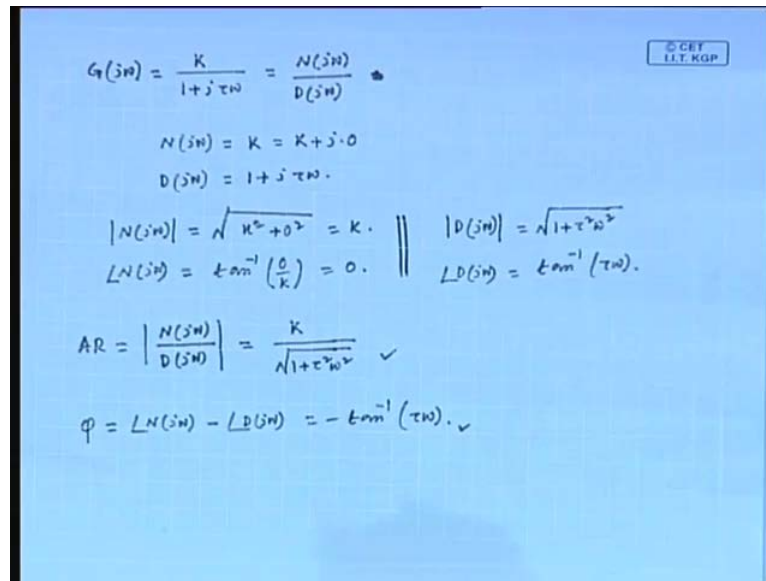

How much is this, amplitude ratio is equal to k divided by root over of 1 plus tau square omega square. Similarly, we can determine the face angle phi.

(Refer Slide Time: 48:27)

The image shows handwritten mathematical derivations on a blue grid background. At the top, the real and imaginary parts of a transfer function are given as $Re(w) = K \left(\frac{1}{1 + \tau^2 \omega^2} \right)$ and $Im(w) = -K \left(\frac{\tau \omega}{1 + \tau^2 \omega^2} \right)$. Below this, 'Step-3' is written, followed by the amplitude ratio (AR) formula: $AR = \sqrt{[Re(w)]^2 + [Im(w)]^2} = \frac{K}{\sqrt{1 + \tau^2 \omega^2}}$. At the bottom, the phase angle ϕ is derived as $\phi = \text{arg}[G(s)] = \angle G(s) = \tan^{-1} \left(\frac{Im(w)}{Re(w)} \right) = -\tan^{-1}(\tau \omega)$.

Which is argument and this phi equals tan inverse, imaginary part divided by real part substituting real and imaginary part, we obtain minus tan inverse tau omega. So, for a first order system having the transfer function $G(s)$ equals k divided by τs plus 1 we obtained the expression for amplitude ratio and phi, representing the frequency response transfer function in Cartesian form. Similarly, we will represent the transfer function frequency response transfer function in polar form, for finding the amplitude ratio and face angle.

(Refer Slide Time: 49:47)

$$G(j\omega) = \frac{K}{1+j\tau\omega} = \frac{N(j\omega)}{D(j\omega)}$$
$$N(j\omega) = K = K + j \cdot 0$$
$$D(j\omega) = 1 + j\tau\omega$$
$$|N(j\omega)| = \sqrt{K^2 + 0^2} = K \quad \parallel \quad |D(j\omega)| = \sqrt{1 + \tau^2\omega^2}$$
$$\angle N(j\omega) = \tan^{-1}\left(\frac{0}{K}\right) = 0 \quad \parallel \quad \angle D(j\omega) = \tan^{-1}(\tau\omega)$$
$$AR = \left| \frac{N(j\omega)}{D(j\omega)} \right| = \frac{K}{\sqrt{1 + \tau^2\omega^2}}$$
$$\phi = \angle N(j\omega) - \angle D(j\omega) = -\tan^{-1}(\tau\omega)$$

The frequency response transfer function we obtained, as $G(j\omega)$ equals k divided by $1 + j\tau\omega$, which can be written as $N(j\omega)$ divided by $D(j\omega)$. Now, what is $N(j\omega)$, $N(j\omega)$ is equal to k . So, you can write this $k + j$ multiplied by 0 and we can write the denominator as $1 + j\tau\omega$, then the magnitude of $N(j\omega)$ is how much k and argument is equal to $\tan^{-1}(0/k)$ which is equal to 0 .

So, we obtain the magnitude and amplitude for the numerator. Similarly, for the denominator we obtain the magnitude as 1 divided by $\tau^2\omega^2$ square root, the real square plus imaginary square whole to the power half and the argument is equal to $\tan^{-1}(\tau\omega)$. Now, we know the amplitude ratio is the ratio of 2 magnitudes, magnitude of numerator divided by denominator magnitude of denominator, then we obtain k divided by root over of $1 + \tau^2\omega^2$ and ϕ is equal to argument of $N(j\omega)$ minus argument of $D(j\omega)$ which is equal to minus $\tan^{-1}(\tau\omega)$.

Now, this 2 expressions we obtained also by representing the frequency response transfer function in Cartesian form.

Thank you.
