Solution of Parabolic PDE: Separation of Variables Method.
(Contd.)

Welcome to the session. So, in this particular session, we will be taking up one actual example in a chemical engineering application and we will forward the governing equation boundary condition. We will go step by step by making it non-dimensional and then, we will be looking into the separation of variable type of solution and finally, we will be constructing the complete solution.

(Refer Slide Time: 00:47)

One dimensional transient heat
Conduction problem. across a plate
Governing Equation

$$\rho C_p \frac{\partial T}{\partial t} = K \frac{\partial^2 T}{\partial x^2}$$

at $t=0$, $T = T_0$ ✓
at $x=0$, $T = T_1$ ✓
at $x=L$, $T = T_2$ ✓

$\theta = \frac{T - T_1}{T_2 - T_1}$ ✓ ; $x^* = x/L$

Now, let us take up one example of chemical engineering application, that is, one dimensional transient heat conduction problem. Now, if you look into the across may be a plate so that we can take recourse to the cartesian coordinate system.

So, if you write down the governing equation, the governing equation to this heat conduction problem becomes $\rho c_p \frac{\partial T}{\partial t} = k \frac{\partial^2 T}{\partial x^2}$. So, we are considering the heat conduction takes place across the, in the x direction and the boundary conditions were at t is equal to 0, temperature was T naught, at x is equal to

0, temperature was T_1 and at x is equal to L , temperature was T_2 .

So, we are maintaining Dirichlet boundary conditions on both the boundaries, at the boundary located at x is equal to 0, we maintain a temperature T_1 , boundary located at x is equal to L , we are maintaining a temperature T_2 . Now, we make this system, first you make this system non-dimensional. Now, you if you if you look into the, let us analyze this problem in a more detail, the analysis go like this. Now, you can identify the number of non-homogeneities number of non-homogeneities in this particular problem. This particular problem consists of three sources of non-homogeneities, one in the initial condition and both the boundary conditions.

So, if you consider the separation of variable, if you remember the principle of linear superposition, this problem has to be divided into three sub-problems considering one non-homogeneity at a time. So, in order to reduce the labor of doing the solution, what do we do, we will define a non-dimensional temperature such that one of the boundary condition becomes homogeneous automatically.

So, therefore, what we will do, we will define a non-dimensional temperature as $T - T_1$ divided by $T_2 - T_1$. What that will do, we can make it $T - T_1$ divided by $T_2 - T_1$, what that will do, that will simply make this boundary condition to be homogeneous, that is at x is equal to 0, T is equal to T_1 .

So, we will be getting, we will be reducing the number of non-homogeneities from 3 to 2. So, please try to understand this point, if we do not do anything, this problem will be having three sources of non-homogeneities, by defining this non-dimensional temperature, we can force the boundary condition at x is equal to 0 to be homogeneous and number of non-homogeneities will be brought down from 3 to 2.

So, we define a non-dimensional temperature θ is equal to $T - T_1$ divided by $T_2 - T_1$, we define a non-dimensional distance as x over L . So, therefore, we put this non-dimensional quantity into governing equation and see what we get.

(Refer Slide Time: 04:57)

Handwritten derivation of the non-dimensional form of the heat conduction equation:

$$\frac{\rho C_p}{(T_2 - T_1)} \frac{\partial \theta}{\partial t} = \frac{k}{L^2} \frac{1}{(T_2 - T_1)} \frac{\partial^2 \theta}{\partial x^2}$$

$$\Rightarrow \frac{\rho C_p}{k} L^2 \frac{\partial \theta}{\partial t} = \frac{\partial^2 \theta}{\partial x^2}$$

$$\Rightarrow \frac{L^2}{\alpha} \frac{\partial \theta}{\partial t} = \frac{\partial^2 \theta}{\partial x^2}$$

$$\Rightarrow \boxed{\frac{\partial \theta}{\partial \tau} = \frac{\partial^2 \theta}{\partial x^2}}$$

Where, $\tau = \frac{\alpha t}{L^2}$ = Non-dimensional time.

Side note: $\frac{k}{\rho C_p} = \alpha$ = thermal diffusivity

$\rho c_p (T_2 - T_1) \frac{\partial \theta}{\partial t}$ is equal to k divided by L^2 $\frac{\partial^2 \theta}{\partial x^2}$. So, $\frac{\partial^2 \theta}{\partial x^2}$ will be $\frac{1}{(T_2 - T_1)} \frac{\partial^2 \theta}{\partial x^2}$. So, we have, this will be cancelling out, so ρc_p over k times L^2 $\frac{\partial \theta}{\partial t}$ is equal to $\frac{\partial^2 \theta}{\partial x^2}$, therefore we define k **rho c k** by ρc_p as α , α is nothing but the thermal diffusivity.

So, therefore, we write it down as $\frac{\partial \theta}{\partial \tau}$ is L^2 by α is equal to $\frac{\partial^2 \theta}{\partial x^2}$. So, therefore, we will be getting $\frac{\partial \theta}{\partial \tau}$ and if you look into α by L^2 , it will be having a unit of second inverse, so this becomes $\frac{\partial \tau}{\partial t}$ is equal to $\frac{\partial^2 \theta}{\partial x^2}$. So, where τ is equal to αt over L^2 , this is a non-dimensional time. So, we get the non-dimensional form of the equation, in fact this is a technique how to make the things non-dimensional.

If some of **the if** the parameter, some parameter is not apparent, how to make it non-dimensional, it is basically, the rule is that you make the those parameters to be non-dimensional with the known values of, with the known parameters and then substitute in the governing equation, so automatically the non-dimensional parameter will be evolving out.

(Refer Slide Time: 07:26)

at $\tau=0$, $\theta = \frac{T_0 - T_1}{T_2 - T_1} = \theta_0$

at $x^*=0$, $\theta = 0$

at $x^*=1$, $\theta = \frac{T_2 - T_1}{T_2 - T_1} = 1$

The non-dimensional form of 1D transient heat conduction Problem:

$$\frac{\partial \theta}{\partial \tau} = \frac{\partial^2 \theta}{\partial x^2}$$

at $\tau=0$, $\theta = \theta_0$ ✓

at $x=0$, $\theta = 0$

at $x=1$, $\theta = 1$ ✓

So, let us **put the** get the boundary conditions in it is non-dimensional form, at t is equal to 0, means at t tau is equal to 0, your T was equal to T naught, so θ was equal to T naught minus T_1 divided by T_2 minus T_1 , so this becomes θ naught. At x is equal to 0, T is equal to T_1 , so your θ becomes is equal to 0. At **x star** x is equal to L means x star is equal to 1, θ becomes T_2 , so **it is** it will be T_2 minus T_1 divided by T_2 minus T_1 , so it will be having 1.

So, therefore, let us write **down the so we so**, these are the boundary conditions in their non-dimensional version, so we **(())** with x star and all these, so you put them as x x . So, the non-dimensional form of one dimensional transient heat conduction problem becomes $\frac{\partial \theta}{\partial \tau} = \frac{\partial^2 \theta}{\partial x^2}$ at τ is equal to 0, θ was equal to θ naught, at x is equal to 0, θ was equal to 0, at x is equal to 1, θ was equal to 1.

So, we solve this problem, we just omitted the x star part, we make it x^2 to make our calculations convenient. So, we are going to solve this equation, so if you now check this equation has now become in the original problem, we had three sources of non-homogeneity and but in this problem, we have only two sources of non-homogeneity.

(Refer Slide Time: 09:53)

$$\theta = \theta_1 + \theta_2$$

$$\theta_1: \quad \frac{\partial \theta_1}{\partial \tau} = \frac{\partial^2 \theta_1}{\partial x^2}$$

$$\begin{array}{l} \text{at } \tau=0, \quad \theta_1 = \theta_0 \\ \text{at } x=0, \quad \theta_1 = 0 \\ \text{at } x=1, \quad \theta_1 = 0 \end{array} \quad \Rightarrow \text{Well Posed Problem}$$

$$\theta_1 = \sum_{n=1}^{\infty} C_n e^{-n^2 \pi^2 \tau} \sin(n \pi x)$$

$$\theta_1(x, \tau) = 2\theta_0 \sum_{n=1}^{\infty} \frac{(1 - \cos(n\pi))}{n\pi} e^{-n^2 \pi^2 \tau} \sin(n\pi x)$$

Now, therefore, this problem has to be divided into two sub-problems, because there are two sources of non-homogeneity. So, we will be having theta is equal to theta 1 plus theta 2, where each such sub-problem will be having only one non-homogeneity at a time. So, therefore, we have the governing equation of theta 1 as del theta 1 del tau is equal to del square theta 1 del x square, **at and** at tau is equal to 0, theta is equal to theta naught, at x is equal to 0, we had theta is equal to 0, at x is equal to 1, we had theta equal to 0. So, we consider theta 1 as this and considering one non-homogeneity at a time, so this if you remember, this is a well posed problem.

Now, if you remember, the solution of this well posed problem is nothing but this will be theta 1, so theta 1 if I remember, this becomes n is equal to 1 to infinity C n e to the power minus n square pi square tau sine n pi x. Since these are the Dirichlet boundary conditions, the eigenvalues are n pi and eigenfunctions are sine n pi x. So, therefore, if you can evaluate C n from the initial conditions **theta 1 is equal to** theta 1 is equal to theta naught and probably we have already solve this problem earlier, I am just putting the complete solution. So, theta 1 as a function of x and tau, will be nothing but 2 theta naught, summation n is equal to 1 infinity one minus cosine n pi divided by n pi e to the power minus n square pi square tau sine n pi x. So, that gives the complete solution of theta 1.

(Refer Slide Time: 12:29)

$\theta_2:$ $\frac{\partial \theta_2}{\partial \tau} = \frac{\partial^2 \theta_2}{\partial x^2}$
 at $\tau = 0, \theta_2 = 0$
 at $x = 0, \theta_2 = 0$
 at $x = 1, \theta_2 = 1$ ✓

} ill posed Problem.

$\theta_2 = \theta_2^s(x) + \theta_2^t(x, t)$

$\frac{\partial \theta_2^t}{\partial \tau} = \frac{d^2 \theta_2^s}{dx^2} + \frac{\partial^2 \theta_2^t}{\partial x^2}$

Next, we will be doing for the theta 2. So, **theta 2 will be** the governing equation theta 2 will be $\frac{\partial \theta_2}{\partial \tau}$ is equal to $\frac{\partial^2 \theta_2}{\partial x^2}$. At τ is equal to 0, we made theta 2 is equal to 0, at x is equal to 0, we had theta 2 is equal to 0 and at x is equal to 1, we had theta 2 is equal to 1. So, **if you** in this sub-problem, we are considering one non-homogeneity, the non-homogeneity at the boundary condition we are considering, forcing the non-homogeneity in the initial condition to be 0.

So, we are considering one non-homogeneity at a time, therefore if you look into the solution of this, this solution we have already looked, so this is an ill posed problem, because we have a 0 initial condition. This problem should be again, we have to make this problem well posed problem, for that this problem will be again broken down into two parts, one is the time varying part or the transient part and another is the steady state part at the time independent part.

So, theta 2 has to be again broken down into two part, one will be theta 2 s, which will be function of x alone, it is a steady state part plus theta 2 t, which is a function of x and t both. Now, exactly the same way you have proceeded earlier, we will be solving this problem $\frac{\partial \theta_2}{\partial \tau}$, we just put these equations there. So, this becomes $\frac{\partial \theta_2^t}{\partial \tau}$ is equal to $\frac{d^2 \theta_2^s}{dx^2} + \frac{\partial^2 \theta_2^t}{\partial x^2}$, we collect the similar order terms and can get the solution of theta 2 and theta s.

(Refer Slide Time: 14:42)

$\theta_2^s: \frac{d^2 \theta_2^s}{dx^2} = 0$
 at $x=0, \theta_2^s = 0$
 at $x=0, \theta_2^s = 0$
 at $x=1, \theta_2^s = 1$
 $\theta_2^s + \theta_2^t = 1$
 at $x=1, \theta_2^s = 1$

$\theta_2^t: \frac{\partial \theta_2^t}{\partial t} = \frac{\partial^2 \theta_2^t}{\partial x^2}$
 at $x=0, \theta_2^t = 0$
 at $x=1, \theta_2^t = 0$
 at $t=0, \theta_2^t = -\theta_2^s(x)$
 Well behaved Probl.
 ✓

So, we formulate theta 2 s as $\frac{d^2 \theta_2^s}{dx^2} = 0$ and at the same time, we will be getting the governing equation theta 2 as $\frac{\partial \theta_2^t}{\partial t} = \frac{\partial^2 \theta_2^t}{\partial x^2}$. So, $\frac{d^2 \theta_2^s}{dx^2} = 0$ will be, **have** let us put it into set the boundary conditions, at x is equal to 0, the original problem is theta 2, in this problem, the original problem, the mother problem becomes theta 2 and theta 2 equal to 0.

So, we have at x is equal to 0, theta 2 s is equal to 0 and at x is equal to 1, theta 2 t is equal to 0, at x is equal to 1, the mother problem theta 2 was having a boundary condition was 1. So, this will be putting theta 2 s plus theta 2 t is equal to 1, so we associate the non-homogeneous term one with theta 2 s, the steady state part. So, at x is equal to 1, my theta 2 s becomes one that forces the boundary condition of the transient part to be homogenous at x is equal to 1.

So, therefore, at x is equal to 1, the theta 2 t will be equal to 0. And now we are in a position to get the initial condition of theta 2, at t is equal to 0, theta 2 was equal to 0 and therefore theta 2 t will be nothing but the solution of the steady state part, which is a function of x . So, this is the boundary condition of the x varying part at x is equal to 0 and this is the complete formulation of theta 2 t, which has a non-homogenous initial condition and homogenous boundary condition, so this is a well behaved problem.

(Refer Slide Time: 17:08)

θ_2^s : Solution: $\theta_2^s = C_1 x + C_2$
 $\Rightarrow C_2 = 0 \Rightarrow \theta_2^s = C_1 x$
 $1 = C_1 \cdot 1 \Rightarrow C_1 = 1$
 $\boxed{\theta_2^s(x) = x}$
 $\frac{\partial \theta_2^t}{\partial t} = \frac{\partial^2 \theta_2^t}{\partial x^2}$
 at $t=0$, $\theta_2^t = -x$ ✓
 at $x=0, 1 \rightarrow \theta_2^t = 0$
 $\theta_2^t = \sum_{n=1}^{\infty} C_n e^{-n^2 \pi^2 t} \sin(n \pi x)$
 $C_n = 2 \int_0^1 f(x) \sin(n \pi x) dx$
 $= -2 \int_0^1 x \sin(n \pi x) dx$

Now, we solve this problem completely, I think that will be important, we get first the **theta the** space varying part θ_2^s solution of that. The solution of θ_2^s is nothing but $C_1 x$ plus C_2 . At x is equal 0, θ_2^s is equal to 0, that means C_2 is equal to 0. So, that gives θ_2^s is equal to $C_1 x$ and at x is equal to 1, θ_2^s was, θ_2^s was 1.

So, therefore, 1 is equal C_1 times 1, therefore will be having C_1 is equal to 1. So, the steady state solution is given as x , so this is the steady state solution. Now, **the** let us look into the transient part, $\frac{\partial \theta_2^t}{\partial t}$ is equal to $\frac{\partial^2 \theta_2^t}{\partial x^2}$ and we have at t is equal to 0, θ_2^t was equal to minus x at x is equal to 0 and 1, both will be having θ_2^t is equal to 0.

So, we have a non-zero initial conditions or non-homogeneous initial condition and homogenous boundary conditions, both the boundaries are Dirichlet in nature. So, $n \pi$ are the eigenvalues and sine functions of the eigenfunction, so θ_2^t will be comprised of summation of C_n , n is equal to 1 to infinity e to the power minus $n^2 \pi^2 t$ $\sin n \pi x$. So, that gives the θ_2^t and what is the value of C_n ? C_n will be twice integral 0 to 1 $f(x) \sin n \pi x dx$. So, the initial condition will be, **the** this $f(x)$ is nothing but minus x .

(Refer Slide Time: 19:31)

$$C_n = -2 \left[-x \cdot \frac{\cos n\pi x}{n\pi} \Big|_0^1 + \int_0^1 \frac{\cos n\pi x}{n\pi} dx \right]$$

$$= -2 \left[-\frac{\cos(n\pi)}{n\pi} + \frac{1}{n^2\pi^2} \sin n\pi x \Big|_0^1 \right]$$

$$= 2 \frac{\cos(n\pi)}{n\pi}$$

$$\theta_2^t = \sum_{n=1}^{\infty} C_n e^{-n^2\pi^2 t} \sin(n\pi x)$$

$$= 2 \sum_{n=1}^{\infty} \frac{\cos(n\pi)}{n\pi} e^{-n^2\pi^2 t} \sin(n\pi x)$$

$$\theta_2(x,t) = \theta_2^s + \theta_2^t = x + 2 \sum_{n=1}^{\infty} \frac{\cos(n\pi)}{n\pi} e^{-n^2\pi^2 t} \sin(n\pi x)$$

So, this will be minus 2 0 to 1 x sin n pi x d x, so if you get that, so we obtain the solution of C n by carrying out this integration by parts. So, minus 2 first function x, integration of second functions will be minus cosine n pi x divided by n pi from 0 to 1 minus differential of first function is 1 minus minus plus cosine n pi x divided by n pi d x from 0 to 1.

So, this becomes minus 2 minus 1 cos n pi divided by n pi minus minus plus, 0 multiplied these things, whole thing becomes 0, this becomes 1 over n square pi square sin n pi x, from 0 to 1 sin n pi is 0 sin 0 is 0. So, no contribution from there, you will be getting minus minus plus 2 cosine n pi over n pi.

So, therefore, C n becomes 2 cosine n pi by n pi and theta 2 t becomes summation of n is equal to 1 to infinity C n e to the power minus n square pi square t sin n pi x. And this C n is 2 summation cosine n pi divided by n pi e to the power minus n square pi square t sine n pi x, n is equal to 1 infinity. So, we complete this problem, so we complete the second problem theta 2 as a function of x and t, theta 2 s plus theta 2 t and theta 2 s was x, so x plus 2 summation n is equal to 1 to infinity cosine n pi divided by n pi e to the power minus n square pi square t sin n pi x.

(Refer Slide Time: 21:51)

$$\theta_1(x,t) = 2\theta_0 \sum \left[\frac{1 - \cos(n\pi)}{n\pi} \right] e^{-n^2\pi^2 t} \sin(n\pi x)$$

$$\theta_2(x,\tau) = \theta_1 + \theta_2$$

$$\theta(x,t) = 2\theta_0 \sum_{n=1}^{\infty} \left\{ \frac{1 - \cos(n\pi)}{n\pi} \right\} e^{-n^2\pi^2 t} \sin(n\pi x) + x + 2 \sum_{n=1}^{\infty} \frac{\cos(n\pi)}{n\pi} e^{-n^2\pi^2 t} \sin(n\pi x)$$

And we have already got the solution of theta 1, so if you remember the solution of part theta 1 as a function of x and t should be is equal to 2 theta naught summation of 1 minus cosine n pi divided by n pi e to the power minus n square pi square t sin n pi x, this t is basically tau. So, theta 1, so the complete solution theta as a function of x and tau should be theta 1 plus theta 2.

So, theta 1 is 2 theta naught summation n is equal to 1 to infinity 1 minus cosine n pi divided by n pi e to the power minus n square pi square t sin n pi x plus x plus 2 summation n is equal to 1 to infinity cosine n pi divided by n pi e to the power minus n square pi square t sin n pi x. So, that gives the complete solution of a transient heat conduction problem in its non-dimensional form.

So, this gives a demonstration how a chemical engineering problem can be solved in it is in the form of by using the separation of variable type of solution. Next, we take up a chemical engineering problem, a one dimensional transient heat conduction problem, but at one of the boundaries, the boundary is insulated, if the boundary is not insulated, there is a constant heat flux that is going putting into the system and we will be having a Neumann boundary condition there.

(Refer Slide Time: 24:12)

1 Dimensional transient heat conduction problem (constant heat flux condition at the wall)

Energy balance: $\rho C_p \frac{\partial T}{\partial t} = k \frac{\partial^2 T}{\partial x^2}$

$\Rightarrow \frac{\partial T}{\partial t} = \alpha \frac{\partial^2 T}{\partial x^2}$ ✓

At $t=0$, $T = T_0$ ✓ $\forall x$ ✓

At $x=0$, $-k \frac{\partial T}{\partial x} = q_0$ ✓

At $x=L$, $T = T_1$ ✓

So, it will be again an example of one dimensional transient heat conduction problem, again we will be solving it completely; constant heat flux condition at the wall. So, the energy balance equation is given by $\rho c p \frac{\partial T}{\partial t}$ is equal to $k \frac{\partial^2 T}{\partial x^2}$. So, we make $\frac{\partial T}{\partial t}$ as k by $\rho c p$, that is $\alpha \frac{\partial^2 T}{\partial x^2}$, α is known as the thermal diffusivity, that will be equal to k by $\rho c p$.

Now, let us put the other boundary conditions, an initial condition, at t equal to 0, temperature was equal to T_0 for any x , for every x , this is true. At x is equal to 0, the boundary at x is equal 0, $-k \frac{\partial T}{\partial x} = q_0$. So, this is the, q_0 is the constant heat flux that is going into system and at x is equal to L , we had, we are maintaining a constant temperature at the wall T is equal to T_1 .

Now, **this there are** if you look into the system, **this** in this system of equations, there are three sources of non-homogeneity, both at the initial condition is non-homogeneous, both the boundary conditions are non-homogeneous. Therefore, what we will do, we make this equation non-dimensional, by making the equation non-dimensional we are getting two benefits at a time. The first one is we make this problem well behaved; that means, the boundaries are made from 0 to 1 and we normalize all the variables, that is number 1; number 2 is that we can judiciously select our non-dimensional variable, so that we can reduce the non-number of non-homogeneities from 3 to 2.

(Refer Slide Time: 27:10)

Non-dimensionalization:

- (i) All the variables are normalized
- (ii) ~~The~~ Sources of non-homogeneity can be reduced.

$$\theta = \frac{T - T_1}{T_0 - T_1} ; \quad x^* = x/L$$
$$\frac{1}{(T_0 - T_1)} \frac{\partial \theta}{\partial t} = \frac{\alpha}{L^2} \frac{\partial^2 \theta}{\partial x^{*2}} \times \frac{1}{(T_0 - T_1)}$$
$$\Rightarrow \frac{\partial \theta}{\partial \tau} = \frac{\partial^2 \theta}{\partial x^{*2}}, \quad \tau = (L^2 t / \alpha)$$

So, therefore, the non-dimensional is necessary, so if you remember, the non-dimensionalization is done because of two things, as I mentioned, first one, it has to be, **the** all the variables are normalized, so, therefore, they are in a domain that can be handled quite easily. And secondly, the number of sources of non-homogeneities can be reduced so that the rigger of calculations will be decreased.

Now, we define a non-dimensional temperature as theta equal to T minus T 1 divided by T 0 minus T 1. If we define this non-dimensional theta, let us see **an** x star is equal to x by L, let us see how the non-dimensional equation looks like. So, this becomes del 1 over T 0 minus T 1 del theta del t is equal alpha del square theta L square del x star square, so into 1 over T 0 minus T 1 is there, so that will be cancelling out. So, this becomes del theta del tau is equal to del square theta del x star square, where tau equal to L square t over alpha.

(Refer Slide Time: 29:26)

$$\frac{\partial \theta}{\partial \tau} = \frac{\partial^2 \theta}{\partial x^{*2}}$$

at $\tau=0$, $\theta=1.0$ ✓

at $x^*=0$, $-\frac{k}{(T_0 - T_1)} \frac{\partial \theta}{\partial x^*} = q_0$

$$\Rightarrow \frac{\partial \theta}{\partial x^*} = - \frac{q_0 L (T_0 - T_1)}{k}$$

at $x^*=1$, $\theta=0$ ✓

2 sources of non-homogeneities:
 1st I.C $\Rightarrow$ B.C. at $x^*=0$

$$\theta_0 = - \frac{q_0 L (T_0 - T_1)}{k}$$

Now, let us use the boundary conditions and make the boundary conditions non-dimensional. So, you just write the equation $\frac{\partial \theta}{\partial \tau} = \frac{\partial^2 \theta}{\partial x^{*2}}$. The non-dimensional temperature at τ is equal to 0, that means at τ is equal to 0, temperature t was equal to t_{naught} , so θ was equal to 1.

At x^* is equal to 0, $-\frac{k}{(T_0 - T_1)} \frac{\partial \theta}{\partial x^*} = q_0$, so $-\frac{k}{(T_0 - T_1)} \frac{\partial \theta}{\partial x^*} = q_0$, so it will be $\frac{\partial \theta}{\partial x^*} = - \frac{q_0 L (T_0 - T_1)}{k}$, so it multiplied by L , $\frac{\partial \theta}{\partial x^*} = - \frac{q_0 L (T_0 - T_1)}{k}$, yeah it will be $\frac{\partial \theta}{\partial x^*}$. The boundary condition at x is equal to 0 $-\frac{k}{(T_0 - T_1)} \frac{\partial \theta}{\partial x^*} = q_0$, so this will be $\frac{\partial \theta}{\partial x^*} = - \frac{q_0 L (T_0 - T_1)}{k}$, so we will be getting $\frac{\partial \theta}{\partial x^*} = - \frac{q_0 L (T_0 - T_1)}{k}$, so we call this as some quantity, let us say this is as θ_0 .

So, θ_0 is nothing but $-\frac{q_0 L (T_0 - T_1)}{k}$ and at x^* is equal to 1, we have τ is equal to T_1 , therefore θ becomes equal to 0. So, now, if you see the boundary conditions and initial condition of this problem, the problem itself is homogenous, the initial condition is non-homogenous, the boundary condition is non-homogenous at x^* is equal to 0, but the boundary condition at x^* equal to 1 is homogenous.

So, therefore, two sources of non-homogeneity in this equation, one is at initial condition and second is at boundary condition at x is equal to x^* is equal to 0. So, we have these two sources of non-homogeneity in this system.

--	---

We consider one non-homogeneity at a time.

Now, therefore, this problem is again divided into 2 sub-problems and if you do that, so this sub-problem will be divided into 2 theta 1 plus theta 2, will be formulating both these sub-problem considering one non-homogeneity at a time. **So, del theta**

So, let us look into definition of theta 1, it will be del theta 1 del tau is equal to del square theta 1 del x star square. So, we make it, we substitute x star by x, so that **the** we need not **to** put star everywhere. So, **at x is equal** at t is equal to, at tau is equal to 0, we had theta is equal to 1, at x is equal to 0, we had del theta del x is equal to theta naught.

At x is equal to 1, we had theta is equal to 0, we make this boundary condition to be 0, we force this boundary condition to be 0. So, for theta 1, we make this boundary conditions, at tau is equal to 0, theta 1 equal to 0, we keep this non-homogeneity with theta 1. And at x is equal to 0, the non-homogeneous boundary condition del theta 1 del x is equal del theta, del x is equal to theta naught, we force it to be 0, so at x is equal to 1, theta 1 is equal to 0.

So, this non-homogeneity, let us associate with the next problem, so theta 2 will be defined as del theta 2 del tau is equal to del square theta 2 del x square, so at tau is equal to 0, we have theta 2 equal to 0. So, if **force** this non-homogeneity is 0, in this case and we will keep the non-homogeneity in the boundary condition intact in the second problem.

At x is equal to 0, $\frac{\partial \theta_2}{\partial x}$ is equal to θ_2 and at x is equal to 1, θ_2 was equal to 0. So, **if you** as you have done earlier, will be divided this problem into 2 sub-problem, considering one non-homogeneity at a time. So, the crux of this problem is that, we consider one non-homogeneity at a time, so in order to do that we have defined these two sub-problems θ_1 and θ_2 .

And if you look into this problem, θ_1 is a well posed problem. Why it is well posed problem, simply because it has a non-homogeneous initial conditions **condition** and homogeneous boundary conditions, on the other hand θ_2 is an ill posed problem. We already know the well posed problem like this and we have already solved it earlier. If you remember the boundary conditions at x is equal to 0 is having a Neumann boundary condition, so the eigenvalues to this problem are $2n - 1$ π by 2 and cosine functions are the eigenfunctions.

(Refer Slide Time: 36:02)

$$\theta_1(x, \tau) = \sum_{n=1}^{\infty} C_n e^{-\alpha_n^2 \tau} \cos(\alpha_n x)$$

$$\alpha_n = (2n-1)\frac{\pi}{2}$$

$$C_n = 2 \int_0^1 f(x) \cos(\alpha_n x) dx$$

$$= 2 \int_0^1 \cos(\alpha_n x) dx$$

$$= \frac{2}{\alpha_n} \sin(\alpha_n x) \Big|_0^1$$

$$= \frac{2 \sin(\alpha_n)}{\alpha_n}$$

$$\theta_1 = 2 \sum_{n=1}^{\infty} \frac{\sin \alpha_n}{\alpha_n} e^{-\alpha_n^2 \tau} \cos(\alpha_n x)$$

So, therefore, we write the solution, we can write the complete solution of θ_1 as a function of x and τ , that will be simply summation of $C_n e^{-\alpha_n^2 \tau} \cos(\alpha_n x)$, where n runs from 1 to infinity, where α_n is equal to $2n - 1$ π by 2. And let us look into what C_n 's are, the C_n 's was 2 summation of $f(x) \cos(\alpha_n x) dx$ from 0 to 1 and what is this $f(x)$, this $f(x)$ was the initial condition at τ is equal to 0.

Now, for this particular problem, $f(x)$ is equal to 1, so the initial condition is equal to 1, therefore we put $\int_0^1 \cos \alpha_n x \, dx$, therefore integration of this will be nothing but $\frac{2}{\alpha_n} \sin \alpha_n x$ from 0 to 1. So, $\sin 0$ is 0, $\sin \alpha_n x$ will be, it will be 1 if you put the upper limit.

This becomes $\frac{2 \sin \alpha_n}{\alpha_n}$ divided by α_n , so the complete solution of first part θ_1 is nothing but $\sum_{n=1}^{\infty} \frac{\sin \alpha_n}{\alpha_n^2} \cos \alpha_n x$, so that is the complete solution of θ_1 part.

(Refer Slide Time: 38:26)

$\theta_2: \quad \theta_2(x, \tau) = \theta_2^s(x) + \theta_2^t(x, \tau)$

$\theta_2^s: \quad \frac{d^2 \theta_2^s}{dx^2} = 0$ at $x=0, \quad \frac{d\theta_2^s}{dx} + \frac{\partial \theta_2^t}{\partial x} = \theta_0$ at $x=0, \quad \frac{d\theta_2^s}{dx} = \theta_0$ at $x=1, \quad \theta_2^s = 0$ at $x=1, \quad \theta_2^s = 0$	$\theta_2^t: \quad \frac{\partial^2 \theta_2^t}{\partial \tau^2} = \frac{\partial^2 \theta_2^t}{\partial x^2}$ at $x=0, \quad \frac{\partial \theta_2^t}{\partial x} = 0 \checkmark$ at $x=1, \quad \theta_2^t = 0 \checkmark$ at $\tau=0, \quad \theta_2^t = -\theta_2^s(x)$
--	--

Now, let us look into the θ_2 part. The θ_2 part is having an ill posed problem, so it has a homogenous initial condition and a non-homogenous boundary condition. So, this problem will be divided into 2 sub parts, one is the time dependent part, another is the time independent part. So, $\theta_2 x$ and τ should be divided into 2 sub-problem, $\theta_2 s$ which is a time varying part and $\theta_2 t$ which is a function of both x and time.

So, we defined the like exactly the same way we have done earlier, $\theta_2 s$ is given as governing equation, so the parent problem for $\theta_2 s$ and $\theta_2 t$ at θ_2 , so $\frac{d^2 \theta_2 s}{dx^2}$ is the governing equation of $\theta_2 s$. And $\theta_2 t$ will be having $\frac{\partial^2 \theta_2 t}{\partial \tau^2} = \frac{\partial^2 \theta_2 t}{\partial x^2}$.

So, boundary conditions of this problem of the steady state part are at x is equal to 0, we have $\frac{\partial \theta_2}{\partial x}$ is equal to θ_0 . So, you put $\frac{\partial \theta_2}{\partial x} + \theta_2$ at $x=0$ is equal to θ_0 . And we intentionally associate the non-homogenous term with the steady state solution, steady state boundary condition, so that boundary condition of the transient problem will be homogenous.

So, at x is equal to 0, we should have $\frac{\partial \theta_2}{\partial x}$ should be is equal to θ_0 , and at x is equal to 1, we should have $\frac{\partial \theta_2}{\partial x} = 0$. At x is equal to 1, we have θ_2 is equal to 0, so therefore, at x is equal to 1, we should have θ_2 is equal to 0 and at x is equal to 1, we should have $\frac{\partial \theta_2}{\partial x}$ is equal to 0.

So, the boundary condition at x is equal to 1 becomes homogenous, the boundary condition at x is equal to 0 for the steady state part is non-homogenous. On the other hand, the boundary condition of the time varying part at x is equal to 0 becomes homogenous, the boundary condition of the time varying part of at x is equal to 1 becomes homogenous.

So, what is the initial condition of the time varying part? At t is equal to 0 or τ is equal to 0, θ_2 will be nothing **minus nothing** but θ_2^s , which is a minus of θ_2^s , which is a solution of the steady state part.

(Refer Slide Time: 41:48)

$$\theta_2^s(x) = C_1 x + C_2$$

$$\frac{d\theta_2^s}{dx} = C_1 \Rightarrow \theta_0 = C_1$$

$$\theta_2^s(x) = \theta_0 x + C_2$$

$$\text{at } x=1, \theta_2^s = 0$$

$$0 = \theta_0 * 1 + C_2 \Rightarrow C_2 = -\theta_0$$

$$\boxed{\theta_2^s = \theta_0(x-1) = -\theta_0(1-x)}$$

Now, let us look into the solution of the steady state part. The solution of the steady state part θ_2^s will be obtained, since $\frac{d^2 \theta_2^s}{dx^2} = 0$, so it is a linear profile $C_1 x + C_2$ at x is equal to 0. $\frac{d \theta_2^s}{dx}$ is equal to C_1 , therefore C_1 must be **is** equal to θ_0 , so θ_0 is equal to C_1 , so therefore θ_2^s is nothing but $\theta_0 x + C_2$. The other boundary is at x is equal to 1, θ_2^s is equal to 0, so, therefore, 0 is equal to θ_0 into 1 plus C_2 , x is equal to 1, so C_2 will be minus θ_0 . So, θ_2^s will be nothing but θ_0 into x minus 1 or minus θ_0 into $1 - x$, so that is the steady state solution.

(Refer Slide Time: 43:17)

Well Posed Prob.

$$\frac{\partial \theta_2^t}{\partial t} = \frac{\partial^2 \theta_2^t}{\partial x^2}$$

$$\left. \begin{array}{l} \text{at } \tau = 0, \quad \theta_2^t = \theta_0(1-x) \rightarrow \text{NH I.C.} \\ \text{at } x = 0, \quad \frac{\partial \theta_2^t}{\partial x} = 0 \\ \text{at } x = 1, \quad \theta_2^t = 0 \end{array} \right\} \text{Hom. B.C.}$$

Eigenvalues: $(2n-1)\pi/2 = d_n$

Eigenfunctions: $\cos[(2n-1)\frac{\pi}{2}x]$

$$\theta_2^t = \sum_{n=1}^{\infty} C_n e^{-d_n^2 t} \cos(d_n x)$$

$$C_n = 2\theta_0 \int_0^1 (1-x) \cos(d_n x) dx$$

Now, let us look into the transient solution. If you remember the θ_2 part, it will be $\frac{\partial \theta_2^t}{\partial t} = \frac{\partial^2 \theta_2^t}{\partial x^2}$. At τ is equal to 0, we have θ_2^t is minus of θ_2^s , so this will be θ_0 into $1 - x$ and at x is equal to 0, we have $\frac{\partial \theta_2^t}{\partial x}$ will be equal to 0. And at x is equal to 1, we have θ_2^t will be equal to 0.

We have already looked into the solution of this problem earlier, so this problem will be having homogenous boundary conditions and a non-homogenous initial condition, so this is a well posed problem. Now, since the boundary condition at x is equal to 0 is Neumann and boundary condition at x is equal to 1 is Dirichlet, the eigenvalues to this problem **where**, so it is the basic problem of Neumann boundary condition, the

eigenvalues are $2n - 1$ and $\pi/2$ and $\cos(2n - 1)\pi/2 x$ are the eigenfunctions.

So, I am not going into detail solution, we have solved this problem several times earlier, the solution will be summation of C_n from $n=1$ to infinity, n is equal to 1 to infinity $C_n e$ to the power minus $\alpha_n^2 t$ $\cos \alpha_n x$, where α_n are eigenvalues $2n - 1$ and $\pi/2$ and C_n is nothing but $2\theta_0 \int_0^1 (1-x) \cos \alpha_n x dx$. So, I am not going to evaluate this integral, you can evaluate this integral for the time being.

(Refer Slide Time: 46:03)

$$\begin{aligned}
 C_n &= 2\theta_0 \left[\int_0^1 \cos(\alpha_n x) dx - \int_0^1 x \cos(\alpha_n x) dx \right] \\
 &= 2\theta_0 \left[\frac{\sin(\alpha_n x)}{\alpha_n} \Big|_0^1 - \frac{\sin(\alpha_n x)}{\alpha_n} \Big|_0^1 + \int_0^1 \frac{\sin(\alpha_n x)}{\alpha_n} dx \right] \\
 &= 2\theta_0 \left[\frac{\sin \alpha_n}{\alpha_n} - \frac{\sin \alpha_n}{\alpha_n} + \frac{1}{\alpha_n^2} \cos \alpha_n \Big|_0^1 \right] \\
 &= 2\theta_0 \left[\frac{1}{\alpha_n^2} (\cos \alpha_n - 1) \right] \quad \cos \alpha_n = 0 \\
 &= -2\theta_0 / \alpha_n^2
 \end{aligned}$$

So, $2t$ is equal to $2\theta_0$, so $\int_0^1 \cos \alpha_n x dx$ minus $\int_0^1 x \cos \alpha_n x dx$. So, this becomes $2\theta_0$, $\cos \alpha_n x$ becomes $\sin \alpha_n x$ divided by α_n , so $\sin \alpha_n x$ divided by α_n from 0 to 1 minus first function integral of the second function, so $\sin \alpha_n x$ divided by α_n from 0 to 1 minus minus plus differential first function 1 integral of the second function, so $\sin \alpha_n x$ divided by $\alpha_n dx$ from 0 to 1.

So, we will be getting $2\theta_0$, this will be $\sin \alpha_n$ divided by α_n minus $\sin 0$ is 0 minus $\sin \alpha_n$ divided by α_n , $\sin 0$ is 0 plus this will be $\cos \alpha_n x$, so 1 by α_n^2 . So, this will be $\cos \alpha_n x$ from 0 to 1, so this becomes $2\theta_0$, these two will be cancelling out, 1 by α_n^2 , this becomes $\cos \alpha_n$ minus $\cos 0$ is 1 .

Now, cosine alpha n is 0, those are the eigenvalues, so this will be 1, so 0, this will be minus 2 theta 0 by alpha n square as we have already seen earlier. So, this is not theta 2, this is basically constant C n.

(Refer Slide Time: 48:19)

$$\theta_2^t(x, \tau) = -\sum_{n=1}^{\infty} \frac{2\theta_0}{\alpha_n^2} e^{-\alpha_n^2 \tau} \cos(\alpha_n x)$$

$$= -2\theta_0 \sum_{n=1}^{\infty} \frac{1}{\alpha_n^2} e^{-\alpha_n^2 \tau} \cos(\alpha_n x)$$

$$\theta(x, \tau) = \theta_1 + \theta_2$$

$$= \theta_1^s + \theta_2^s + \theta_2^t$$

So, theta 2 t, now we are in a position to write the complete solution of theta 2 t. So, theta 2 t as a function of x and tau, should be minus 2 theta 0 by alpha n square, so that is a summation there, e to the power minus alpha n square tau cosine alpha n x, n is equal 1 to infinity. So, you can take minus 2 theta 0 common, so it will be 1 by alpha n square e to the power minus alpha n square tau cosine alpha n x, so n is equal to 1 to infinity.

So, that gives the complete solution of theta 2 t, similarly therefore, you can construct the overall solution theta of our original problem, it was **equal** divided into two parts theta 1 as a theta 1 plus theta 2 and we completely solved the theta 1 part and theta 2 part. We had two parts, theta 2 steady state plus theta 2 transient and **we have** we have completely solved the theta 2 s, we have completely solved theta 2 t, we have completely solved theta 1, so summation of all this three parts will give rise to the complete solution of theta.

(Refer Slide Time: 49:58)

A transient, 1D heat conduction problem across a metallic plate
one boundary is exposed to atmospheric convection.

Gov. Eqn. $\rho C_p \frac{\partial T}{\partial t} = K \frac{\partial^2 T}{\partial x^2}$ ✓

at $t=0$, $T = T_0$ ✓

at $x=0$, $T = T_1$ ✓

at $x=L$, $-K \frac{\partial T}{\partial x} = h(T - T_\infty)$ ✓

$\theta = \frac{T - T_\infty}{T_0 - T_\infty}$

Now, I would like to take up a complete chemical engineering problem, where one of the boundary condition is a robin mixed boundary condition, so it is again a transient heat conduction problem in one dimensional. Transient one dimensional heat conduction problem across a plate, across a metallic plate such that the boundary at x is equal to 1 is opened to atmosphere.

So, if we write down the energy balance, one boundary is exposed to atmospheric convection, so this is the one dimensional heat conduction problem with a mixed boundary condition. We will be just looking into that, let us write down the governing equation, governing equation is nothing but the energy balance equation, $\rho c p \frac{\partial T}{\partial t}$ is equal to $k \frac{\partial^2 T}{\partial x^2}$, that is the governing equation at time t is equal to 0.

We have an initial temperature, let us say T at x is equal to 0, let us say, we have a temperature, we maintain a temperature T_1 and at x is equal to L , the end of the thickness L , the boundary is opened atmosphere. So, whatever the energy that comes by conduction is taken away by convection of, **by** taken away convection of the ambient environment, h is the heat transfer coefficient and T_∞ is the temperature of the surroundings.

So, $h(T - T_\infty)$ is the amount of heat flux that is taken away from the boundary and that should be equal to amount of heat flux that is arriving at that boundary

by conduction by minus $k \frac{\partial T}{\partial x}$. Now, if you look into this problem, the governing equation is homogenous, the initial condition is non-homogenous, the boundary condition at x is equal to 0 is non-homogenous and boundary condition at x is equal to L is also non-homogenous because of the presence of term T_{∞} there.

So, we define this problem, we make this problem non-dimensional, so that the number of non-homogeneities can be reduced significantly and we are aiming to reduce the number of non-homogeneity at least 1. So, if we define a non-dimensional temperature as T minus T_{∞} divided by T_0 minus T_{∞} and then probably we can get down the number of non-homogeneities to 2 from 3.

(Refer Slide Time: 53:30)

The image shows a handwritten derivation on a blue background. It starts with the heat conduction equation:
$$\rho C_p (T_0 - T_{\infty}) \frac{\partial \theta}{\partial t} = \frac{k}{L^2} \frac{\partial^2 \theta}{\partial x^{*2}} \cdot \frac{1}{(T_0 - T_{\infty})^{-1}}$$
 This is simplified to:
$$\Rightarrow \frac{\partial \theta}{\partial t} = \frac{\alpha}{L^2} \frac{\partial^2 \theta}{\partial x^{*2}}$$
 Then, it defines the non-dimensional temperature θ as:
$$\theta = \frac{T - T_{\infty}}{T_0 - T_{\infty}}$$
 and the non-dimensional time τ as:
$$\tau = \frac{t \alpha}{L^2}$$
 The boundary conditions are given as:
$$\text{at } \tau = 0, \theta = 1$$

$$\text{at } x^* = 0, \theta = \frac{T_1 - T_{\infty}}{T_0 - T_{\infty}} = \theta_0$$

$$\text{at } x^* = 1, -\frac{k}{L} \frac{\partial \theta}{\partial x^*} = h \theta (T_1 - T_{\infty})$$
 The final non-dimensional governing equation is:
$$\frac{\partial \theta}{\partial \tau} + \frac{hL}{k} \theta = 0; \quad Bi = \frac{hL}{k}$$

So, if you really do that, let us see what the fate of the governing equation is. The governing equation of non-dimensional **form** will be $\rho C_p \frac{1}{T_0 - T_{\infty}} \frac{\partial \theta}{\partial t}$ is equal to $\frac{k}{L^2} \frac{\partial^2 \theta}{\partial x^{*2}}$. There will be $1/T_0 - T_{\infty}$ in the denominator, this 2 will be cancelled out, so you will be getting $\frac{\partial \theta}{\partial t}$ is equal to $\frac{\alpha}{L^2} \frac{\partial^2 \theta}{\partial x^{*2}}$. So, α is the thermal diffusivity, so you can define $\frac{\partial \theta}{\partial \tau}$ is equal to $\frac{\partial^2 \theta}{\partial x^{*2}}$.

But, τ is equal to $t \alpha / L^2$, this is the non-dimensional type. So, this is the governing equation of non-dimensional governing equation heat conduction problem.

Now, let us make the boundary condition non-dimensional, at t is equal 0, means at τ is equal to 0, t is equal to t_{naught} , therefore θ becomes $T_{\text{naught}} - T_{\infty}$ divided by $T_{\text{naught}} - T_{\infty}$ is equal to 1. At x is equal to 0, that means at x^* is equal to 0, t is equal to T_1 , therefore θ is equal to $T_1 - T_{\infty}$ divided by $T_0 - T_{\infty}$, let us put it as θ_0 .

And at x^* is equal to 1, so we will be having $-k \frac{\partial \theta}{\partial x^*}$, $\frac{\partial \theta}{\partial x^*}$ means $\frac{1}{T_0 - T_{\infty}}$ minus $\frac{1}{T_{\infty} - T_1}$, $\frac{\partial \theta}{\partial x^*}$ that means $\frac{1}{L}$ over $\frac{\partial x^*}{\partial x}$ is equal to $\frac{h}{k} \frac{T_0 - T_{\infty}}{T_1 - T_{\infty}}$, we are writing $\frac{T_0 - T_{\infty}}{T_1 - T_{\infty}}$ as θ_0 into $\frac{1}{T_0 - T_{\infty}}$. In fact, $\frac{T_0 - T_{\infty}}{T_1 - T_{\infty}}$ will be coming in the numerator, so I think this will be minus 1, this will be in inverse, so they will be on the numerator, they will be cancelling out, does not matter. So, these two also will be cancelled out, so we will be having $-\frac{\partial \theta}{\partial x^*}$ plus $Bi \theta$ is equal to 0.

(Refer Slide Time: 56:27)

$$\text{At } x^*=1, \quad \frac{\partial \theta}{\partial x^*} + Bi \theta = 0$$

Biot no.

So, if you remember that what is hL over k , hL over k is nothing but the Biot number. So, we write Biot number is equal to hL over k , so the non-dimensional form of temperature at this boundary becomes at x^* is equal to 1, is $-\frac{\partial \theta}{\partial x^*}$ plus $Bi \theta$, Bi is the Biot number. So, we made this governing equation to be non-dimensional and we will just see there how many number of **you know...** we have reduce the number of non-homogeneities from 3 to 2.

And I will stop here in this class; in the next class, will just see how this problem can be handled and divide into sub-problems and how the complete solution will be evolved out of this problem. And will be getting a complete solution of one dimensional transient heat conduction with one boundary is expose to the atmosphere, so that we will be having a, dealing with a mixed boundary condition; thank you very much.
