Solution of non-homogenous PDE (Contd.)

(Refer Slide Time: 00:27)

Welcome to the session. We are discussing about the construction of causal Green's function. Now, if the actual problem is given as Lu is equal to f , in the case of construction of causal Green's function, we have to keep 3 things in mind. One is the L remains same; second: f is replaced by a Dirac delta function or unit step and three is that boundary conditions of g , the causal Green's function are forced to 0.

Construction

Consider, $Lg(x/x_0) = \delta(x-x_0)$

Subject to, $B_1: g=0$ at $x=0$
 $B_2: g=0$, at $x=1$

Actual Problem: $Lu = f$; $u=1$ at $x=0$
 $u=2$ at $x=1$

Actual Probl	Causal G.F.
$Lu = f$	$Lg(x/x_0) = \delta(x-x_0)$
at $x=0$, $\frac{\partial u}{\partial x} = q_0$	at $x=0$, $\frac{\partial g}{\partial x} = 0$
at $x=1$, $\frac{\partial u}{\partial x} + \beta u = u_3$	at $x=1$, $\frac{\partial g}{\partial x} + \beta g = 0$

So, with this, let us go ahead with the formulation of construction of causal Green's function. Consider $Lg(x/x_0) = \delta(x-x_0)$. That is, L we will be obtaining from the actual problem. Lu is equal to f subject to boundary condition, $B_1: g$ is equal to 0 at x is equal to 0, subject to boundary condition 2: that is, g is equal to 0 at x is equal to 1.

Now, we consider the actual problem is having the Dirichlet boundary condition at x is equal to 0 and x is equal to 1. That means, what is the actual problem? We can construct this causal Green's function, if we have the actual problem as something like this. L of u is equal to f u is equal to 1; at x is equal to 0, u is equal to 2; at x is equal to 1, u may be 1. u may be homogeneous or u may be non-homogeneous, but they are Dirichlet boundary conditions. So, there are Dirichlet.

Now, I will give some of the example on how to construct. Now, this is the actual one - actual problem. This is the causal Green's function. In the actual problem, we have let us say Lu is equal to f ; at x is equal to 0, $\frac{\partial u}{\partial x}$ is equal to let us say, q_0 ; at x is equal to 1, $\frac{\partial u}{\partial x} + \beta u$ is equal to u_3 . If this is the actual problem, then causal Green's function should be $Lg(x/x_0) = \delta(x-x_0)$; at x is equal to 0, identical boundary condition. We force the boundary condition to be homogenous. So, $\frac{\partial g}{\partial x}$ is equal to 0. At x is equal to 1, we keep this form of

boundary, but force it to be homogenous; that is all we do. So, $\frac{d}{dx} g + \beta g$ should be equal to 0. So, we make them homogeneous.

(Refer Slide Time: 04:28)

Consider $Lg(x/x_0) = \delta(x-x_0)$
 at $x=0$, $g(x/x_0) = 0$
 $x=1$
 Across x_0 , we divide the problem in two domains
 $0 < x < x_0$ & $x_0 < x < 1$
 For $0 < x < x_0$
 $Lg = 0$, at $x=0$, $g = 0$
 For $x_0 < x < 1$
 $Lg = 0$ at $x=1$, $g = 0$

Now, let us typically formulate the problem. So, we consider $Lg(x/x_0)$ should be equal to $\delta(x - x_0)$, subject to at x is equal to 0 and at x is equal to 1, g of x slash x_0 ; these are equal to 0.

Let us say, we have the Dirichlet boundary condition in the original problem. So, we divide the problem into 2 sub-parts. Across x_0 - the point at which we are applying the unity impulse; across x_0 , we divide the problem in 2 domains.

One is x lying between 0 and x_0 and another is x lying in between x_0 and 1. Now, for the domain of x lying in between 0 and x_0 , we have Lg equal to 0 and boundary condition of this will be at x is equal to 0, we have g is equal to 0; for x lying in between x_0 and 1, we have Lg is equal to 0; at x is equal 1 g is equal to 1.

Just see the formulation, $Lg(x/x_0)$ is equal to $\delta(x - x_0)$. That means your Dirac delta function is imposed at x is equal to x_0 . If you look into the property of the Dirac delta function that at x is equal x_0 , it is having a value 1. For every other x , which is not equal to x_0 , its value is 0. So, that is the property of how Dirac delta function is defined at x is equal to x_0 , its value is 1 - unit step function and every other value of x except x is equal to x_0 , its value is 0.

So, the way, we have defined it is we have not included x is equal to x_{naught} . We have included the lower domain x from 0 to x_{naught} , which is less than x_{naught} . It is not x_{naught} ; it is x_{naught} minus x_{epsilon} and is less than x_{naught} .

So, the Dirac delta function in that domain will be equal to 0 because its value is 1 exactly at x is equal to x_{naught} , but its value is equal to 0 everywhere else.

So, Lg is equal to 0 and we have the homogenous boundary condition at x is equal to 0, g is equal to 0. Similarly, the upper half solution between 1 and x_{naught} , but we are not including x_{naught} is less than equal to x . We are not including x is equal x_{naught} ; we are excluding x equal to x_{naught} .

So, for the upper half solution, x lying between x_{naught} and 1, the Dirac delta function is 0. So, we will be having Lg is equal to 0 and at x is equal to 1, we have the boundary condition at g is equal to 0.

Now typically, the x varying part is one will be landing up with an equation, which will be having order 2. So, for the order 2, we break down this problem into 4 sub-problems. Each of the sub-problem will be having a lower half solution; we call this a lower half solution; this is an upper half solution.

Since L is an operator of order 2, we need to specify 2 boundary conditions on Lg is equal 0 in order to solve this equation completely. On the other hand, even in the upper half plane, we need to have 2 boundary conditions to be used in order to solve this problem completely.

So, we need to have 4. Since we have 2 equations and 4 unknown, we need to have 4 boundary constant boundary conditions, but we have only 2 boundary conditions. So, we need to search 2 more boundary conditions and see what we get.

(Refer Slide Time: 09:06)

$u_1(x)$ is the solution of lower half plane.
 u_2 is the solution of upper half plane.
 $u(x) = A u_1(x) + B u_2(x)$ for $0 < x < x_0$
 $= C u_1(x) + D u_2(x)$ for $x_0 < x < 1$
 $Lg = 0$
 4 Constants / 2 boundary conditions

So, $u_1(x)$ is the solution of lower half plane and u_2 is the solution of upper half plane. Therefore, u_1 is nothing, but A some solution let us say, it will be. Only the u of x will be constructed of 2 solutions, $A u_1(x)$ plus $B u_2(x)$, for x lying between 0 and x_0 , is equal to $C u_1(x)$ plus $D u_2(x)$, for x lying between x_0 and 1.

This $u_1(x)$ is not the upper half solution; this is the lower half solution; this is the upper half solution and what is this u_1 and u_2 ? u_1 and u_2 are basically L of g is equal to 0.

So, the general solution, you will be getting 2 parts. u_1 and u_2 and this u_1 and u_2 will be related to u ; only the constants will be varied.

So, therefore, you will be having 4 constants A, B, C, D and you need to have 4 boundary conditions to be specified. We have the boundary conditions specified at x is equal to 0; we have boundary condition specified at x is equal to 1.

(Refer Slide Time: 11:28)

2 more BCs

① Continuity of G.F.

$$g(x_0^+/x_0) = g(x_0^-/x_0)$$

(2) Jump discontinuity condition.
 if, $a_0(x) \frac{d^2g}{dx^2} = \delta(x-x_0)$ is gov. eq. of g

$$\int_{x_0-\epsilon}^{x_0+\epsilon} \frac{d^2g}{dx^2} dx = \int_{x_0-\epsilon}^{x_0+\epsilon} \frac{\delta(x-x_0)}{a_0(x)} dx$$

So, 4 constants and we have 2 boundary conditions. Anyway, I will be taking up one example to demonstrate whatever I am saying. Rest 2 boundary conditions, we need to find out. So, 2 more boundary conditions, we need to find out. The first boundary condition will be - first extra boundary condition will be continuity of Green's function. This will be $g(x_0^+/x_0) = g(x_0^-/x_0)$.

Across x_0 , Green's function is continuous. Second one is called a jump discontinuity condition. In this case, if $a_0(x) \frac{d^2g}{dx^2} = \delta(x-x_0)$ is the governing equation for g , where a_0 can be in general function of x , then let us integrate across $x_0 - \epsilon$ to $x_0 + \epsilon$.

We multiply both side by dx and integrate it out. So, $\frac{d^2g}{dx^2}$ is nothing, but $\delta(x-x_0)$ divided by a_0 as a function of x . Multiply both side by dx and integrate across $x_0 - \epsilon$ to $x_0 + \epsilon$ and here also, $x_0 - \epsilon$ to $x_0 + \epsilon$.

So, if you carry out this integration, what you will be getting is that, the right hand side is very simple. We use the shifting property of the Dirac delta function or the unit step function. It will be integration of $f(x)$ multiplied by $\delta(x-x_0)$ across x_0 is nothing, but $f(x_0)$.

(Refer Slide Time: 13:52)

The image shows a handwritten derivation on a blue background. It starts with the integral equation:

$$\int_{x_0-\epsilon}^{x_0+\epsilon} \frac{d^2g}{dx^2} dx = \frac{1}{a_0(x_0)}$$

Then, it shows the evaluation of the integral using the fundamental theorem of calculus:

$$\left. \frac{dg}{dx} \right|_{x_0-\epsilon}^{x_0+\epsilon} = \frac{1}{a_0(x_0)}$$

Next, it shows the difference of the derivatives at the discontinuity:

$$\left. \frac{dg}{dx} \right|_{x_0^+} - \left. \frac{dg}{dx} \right|_{x_0^-} = \frac{1}{a_0(x_0)}$$

Finally, it concludes with an arrow pointing to the text:

→ 4th B.C. [Jump discontinuity condition]

So, what we will be getting is $\frac{d^2g}{dx^2} dx$ from $x_0 - \epsilon$ to $x_0 + \epsilon$ is equal to $\frac{1}{a_0(x_0)}$.

Now, integration of this will be giving you $\frac{dg}{dx}$ from $x_0 - \epsilon$ to $x_0 + \epsilon$ is equal to $\frac{1}{a_0(x_0)}$. So, $\frac{dg}{dx}$ evaluated at $x_0 + \epsilon$ minus $\frac{dg}{dx}$ evaluated at $x_0 - \epsilon$ is equal to $\frac{1}{a_0(x_0)}$.

This gives the fourth boundary condition and also this is known as jump discontinuity condition. **that means** How will you evaluate?

So, we will be having 2 solutions of g : one is the lower half solution; another is the upper half solution. $\frac{dg}{dx}$ evaluated at $x_0 + \epsilon$ means, we evaluate the upper half solution and evaluate it at $x_0 + \epsilon$ and making ϵ tends to 0.

On the other hand, this simply means, we have the lower half solution, we take the x derivative of lower half solution, evaluate it at $x_0 - \epsilon$, and then allow ϵ to tend to 0.

We will be computing this term and that will be equal to $\frac{1}{a_0(x_0)}$. So, this will be giving you one more equation in order to solve the fourth boundary condition.

(Refer Slide Time: 16:04)

Ex1: $\frac{d^2g(x|x_0)}{dx^2} = \delta(x-x_0)$

at $x=0, \quad g(x|x_0)=0$
 $x=1$

For, $0 \leq x < x_0$, $\frac{d^2g_1}{dx^2} = 0$ $g_1 \rightarrow$ lower half solution
 For, $x_0 < x \leq 1$, $\frac{d^2g_2}{dx^2} = 0$ $g_2 \rightarrow$ upper half solution.

B.C. $\Rightarrow$ at $x=0$, $g_1 = 0$
 at $x=1$, $g_2 = 0$

Continuity of h.f.: $g_1(x_0^-) = g_2(x_0^+, x_0)$

$\frac{d^2u}{dx^2} = \delta(x-x_0)$
 at $x=x_0$, $u=1$
 at $x=1$, $u=2$

Let us take up one example and demonstrate how to get the Green's function. The first example, we will be taking is d^2g . So, it is 1-dimensional problem. $d^2g/dx^2 = \delta(x-x_0)$.

So, original problem should have been $d^2u/dx^2 = 5x$; that is the non-homogeneous term. We are replacing the non-homogeneous term by the Dirac delta function and subject to at x is equal to 0 and at x is equal to 1, my g is equal to 0. That means correspondingly, we had at x is equal to 0, u may be equal to 1; at x is equal to 1, u may be equal to 2, but in this case, both of the boundary conditions are Dirichlet and they may be non-homogeneous, may be homogeneous, but in the formulation of Green's function, we force the non-homogeneous boundary conditions to be homogeneous.

Now, let us try to solve this problem. We divide this problem into sub-problem: for x lying in between 0 and x_0 , we have $d^2g_1/dx^2 = 0$; g_1 is the lower half solution and for x lying between x_0 and 1, we have $d^2g_2/dx^2 = 0$.

So, g_1 is lower half solution and g_2 is upper half solution. **and we have the continuity of Green's function, through the boundary condition.** Let us fix up the boundary conditions. At x is equal to 0, g_1 is equal to 0; at x is equal to 1, g_2 is equal to 0 because g_2 is the upper half part. Continuity of Green's function, you have the third boundary condition.

Green's function, this will be $g_1(x)$ minus $g_2(x)$ is equal to $g_2(x)$ plus $\delta(x - x_0)$.

(Refer Slide Time: 19:09)

Handwritten derivation of the jump discontinuity condition for Green's functions. The text is written on a blue background with a small logo in the top right corner that reads "CET I.I.T. KGP".

Jump discontinuity:

$$\int_{x_0-\epsilon}^{x_0+\epsilon} \frac{d^2 g}{dx^2} dx = \int_{x_0-\epsilon}^{x_0+\epsilon} \delta(x - x_0) dx$$

$$\Rightarrow \left. \frac{dg}{dx} \right|_{x_0-\epsilon}^{x_0+\epsilon} = 1$$

$$\Rightarrow \left[\left. \frac{dg_2}{dx} \right|_{x_0+\epsilon} - \left. \frac{dg_1}{dx} \right|_{x_0-\epsilon} \right] = 1$$

For lower half solution: $\frac{d^2 g_1}{dx^2} = 0, \quad 0 \leq x < x_0$

$g_1(x) = Ax + B$

For upper half: $\frac{d^2 g_2}{dx^2} = 0, \quad x_0 < x \leq 1$

The jump discontinuity condition: this will give you $\frac{d^2 g}{dx^2}$, we start with the original problem, is equal to $\delta(x - x_0)$; we multiply both side by dx ; integrate over $x_0 - \epsilon$ to $x_0 + \epsilon$. So, this will be $\frac{dg}{dx}$ evaluated at $x_0 - \epsilon$ to $x_0 + \epsilon$ and that will be equal to 1. What is $\frac{dg}{dx}$? This will be $\frac{d^2 g}{dx^2}$, evaluated at $x_0 + \epsilon$. So, it is the upper half solution, differentiation of that evaluated at $x_0 + \epsilon$ minus lower half solution, differentiation of that $\frac{dg_1}{dx}$ at $x_0 - \epsilon$ is equal to 1.

So, this gives the fourth boundary condition or the jump discontinuity condition. Now, let us solve the problem. Let us look into the lower half solution. We had $\frac{d^2 g_1}{dx^2}$ is equal to 0 for x lying in between 0 and x_0 . Therefore, what is the solution of this? Solution is nothing, but $Ax + B$ and for upper half solution, upper half we have $\frac{d^2 g_2}{dx^2}$ is equal to 0, where x lying in between x_0 and 1.

(Refer Slide Time: 21:30)

$$g_2(x/x_0) = Cx + D$$

at $x=0$, $g_1 = 0 \Rightarrow 0 = B$

at $x=1$, $g_2 = 0 \Rightarrow 0 = C + D \Rightarrow C = -D$

$\therefore g_1(x/x_0) = Ax$

$g_2(x/x_0) = (1-x)D$

Continuity of G.F. $Ax_0 = (1-x_0)D \dots \checkmark$

Jump discont. $\frac{dg_2}{dx} \Big|_{x_0+\epsilon} - \frac{dg_1}{dx} \Big|_{x_0-\epsilon} = 1$

$-D - A = 1$

$\Rightarrow \boxed{-D - 1 = A} \checkmark$

So, g_2 will be equal to Cx plus D .

So, we have 4 constants A, B, C, D . Now, at x is equal 0, we have g_1 is equal to 0; therefore, 0 is equal B . At x is equal 1, we have g_2 is equal to 0. That means, 0 is equal to C plus D ; therefore, C is equal to minus D .

So we have $g_1(x/x_0)$ is nothing, but Ax , $g_2(x/x_0)$ this will be nothing but, $1 - x$ times D . Next, we do the continuity of Green's function. Continuity of Green's function is across x_0 , g_1 and g_2 are equal. So, we will be getting Ax_0 is equal to $1 - x_0$ times D .

So, that is the one and next, we will be getting the jump discontinuity condition for this particular problem. This will be $\frac{dg_2}{dx}$ evaluated at $x_0 + \epsilon$ minus $\frac{dg_1}{dx}$ evaluated at $x_0 - \epsilon$ should be equal to 1. What is $\frac{dg_2}{dx}$? $\frac{dg_2}{dx}$ is nothing, but minus D ; so, this will be minus D . minus $\frac{dg_1}{dx}$ is nothing, but A , should be is equal to 1. So, A is equal to minus D minus 1. That is the definition of A . [A will be the line will be minus.]

(Refer Slide Time: 24:12)

$$A = -D - 1$$

$$A x_0 = (1 - x_0) D$$

$$\Rightarrow -D x_0 - x_0 = D - D x_0$$

$$\Rightarrow \boxed{D = -x_0} ; \quad \boxed{A = x_0 - 1}$$

$$g_1(x/x_0) = (x_0 - 1)x$$

$$g_2(x/x_0) = -x_0(1 - x)$$

$$\boxed{g(x/x_0) = \begin{cases} x(x_0 - 1) & \text{for } 0 < x < x_0 \\ -(1 - x)x_0 & \text{for } x_0 < x < 1 \end{cases}}$$

Now, we can solve these two equations and see what you get from these two equations. We will be getting the constants A and D and we can evaluate these two. So, I will just solve it. A is equal to minus D minus 1; the other equation is Ax_0 is equal to $1 - x_0$ times D. So, I just put A is equal to minus D minus 1. $-Dx_0 - x_0$ is equal to $D - Dx_0$. So, Dx_0 minus Dx_0 will cancel out. It will be D is equal to minus x_0 . So, that will be 1 and similarly, one can get A is equal to minus D minus 1; so minus, minus - plus x_0 minus 1. Therefore, this is the last other constant A; C and B we have already developed.

So, therefore, $g_1(x/x_0)$ is equal to Ax . So, $x_0 - 1$ times x and $g_2(x/x_0)$ is equal to $1 - x_0$ times D; D is minus x_0 into $1 - x$. Therefore, we can write down the expression of Green's function as: lower half solution is $g_1(x/x_0)$ is $x_0 - 1$ for x lying in between 0 and x_0 ; the upper half solution is that minus 1 minus x times x_0 .

So, it will be for upper half solution. So, we divide it into 2 parts, excluding x_0 . So this gives the general expression of g for the 2 parts.

That is how, one will be able to solve the Green's function in 1-dimensional form. Now, let us try to solve one problem using Green's function method and we demonstrate this method for 1- dimensional problem only. I recover this solution later on.

(Refer Slide Time: 26:51)

Ex 2: $\frac{d^2u}{dx^2} = x$ ① Subj to $\left. \begin{matrix} u=0 \\ u=0 \end{matrix} \right\} \begin{matrix} \text{at } x=0 \\ \text{at } x=1 \end{matrix}$

Using Green's function:
Construct Causal G.o.F. :
 $\frac{d^2g(x|x_0)}{dx^2} = \delta(x-x_0)$ ② $L = \frac{d^2}{dx^2}$

Subj to, $\left. \begin{matrix} \text{at } x=0, \\ x=1 \end{matrix} \right\} \begin{matrix} g=0 \\ g=0 \end{matrix}$

For laplacian operator, $L = L^*$

We relate u with g .

So, let us get into the second example. This example is we like to solve d^2u/dx^2 is equal to let us say, x subject to u is equal to 0, at x is equal to 0 and u is equal to 0, at x is equal to 1.

Let us try to solve this problem using Green's function method. We have considered the boundary conditions are Dirichlet and homogeneous. Now, construct causal Green's function, that will be simply $d^2g(x|x_0)/dx^2$ is equal to $\delta(x-x_0)$ minus x naught. We replace the non-homogeneous part of the governing equation by a Dirac delta function, subject to at x is equal to 0, g is equal to 0 and at x is equal to 1, g is equal to 0.

Next, what we do? We assume for the time being and we can prove it later on that Laplacian operator is a self adjoint operator, we have already proved earlier. Probably, in the earlier classes, we have proved for Laplacian operator is a self adjoint operator; L is equal to L^* . We have already proved this thing earlier. Therefore, since Laplacian operator is a self adjoint operator, we need not to find an adjoint Green's function in this problem because the operator itself is self adjoint.

So, therefore, if you remember the steps of solving the equation, first you construct the causal Green's function. We solve the causal Green's function, then we go for the adjoint Green's function and then we go for the connection of relation of adjoint, relate the adjoint Green's function with the original problem.

But if you look into this problem since this Laplacian operator L is d^2/dx^2 , in this case and we have already proved earlier that Laplacian operator is a self adjoint operator, we need not go for adjoint operator and adjoint Green's function.

(Refer Slide Time: 30:28)

$$\begin{aligned}
 \langle 1, g \rangle - \langle 2, u \rangle &= \int_0^1 g \frac{d^2 u}{dx^2} dx - \int_0^1 u \frac{d^2 g}{dx^2} dx = \int_0^1 x g dx - \int_0^1 u \delta(x-x_0) dx \\
 &= \int_0^1 x g dx - u(x_0) \\
 &= \int_0^1 x g dx - u(x_0) \\
 \boxed{u(x_0) = \int_0^1 x g dx}
 \end{aligned}$$

We can **directly** connect Lg is equal to delta to Lu is equal to f directly because the operator is itself a self adjoint operator. So, we connect or we relate u with g . How to do that? We multiply both side of 1 with g and integrate it - that means, we take the inner product of 1 with respect to g and integrate it; we take the inner product of 2 with respect to u and then we subtract and see what we get - that means, inner product of 1 with respect to g minus inner product of 2 with respect to u and see what you get. So, if you do that inner product in continuous function is nothing, but integration - g times $d^2 u/dx^2$ minus u times $d^2 g/dx^2$ is equal to integration x times $g dx$ minus $u \delta(x-x_0)$; all this integration is over the domain of x from 0 to 1.

Now, let us see what we get out of it. Now, we integrate it by parts. g first function integration of second function is $du dx$ from 0 to 1 minus differential of first function $dg dx$, integration of the second function $u dg dx$ from 0 to 1 minus first function integration of second function $u dg dx$ from 0 to 1; minus, minus - plus integration differential of first function $du dx$, integration of second function $dg dx$ is equal to 0 to 1 $x g dx$ minus, use the shifting property of Dirac delta function so this will be nothing, but u of x naught.

Now, these two will be simply cancelling out; they are equal and opposite in side. So, what we will be getting is g at 1, u prime at 1 minus g at 0, u prime at 0 minus u at 1, g prime at 1, minus, minus - plus u at 0, g prime at 0 is equal to integral 0 to 1 $x g dx$ minus u of x naught. Now, the boundary condition of the original problem was u equal to 0 at x equal to 0, u was equal to 0; so, this term will be off; boundary condition in the original problem at x is equal to 1, u is equal to 0; so, this will be gone and the boundary conditions on g they are always homogeneous. This is gone and this is gone. So, the whole left hand side will be equal to 0. So, what we can have, we have u of x naught is nothing, but $x g dx$ from 0 to 1.

(Refer Slide Time: 33:40)

$$\begin{aligned}
 g(x|x_0) &= x(x_0-1) \text{ for } 0 \leq x < x_0 \\
 &= -(1-x)x_0 \text{ for } x_0 \leq x \leq 1 \\
 u(x_0) &= \int_0^1 x g dx = \int_0^{x_0} g_1(x) dx + \int_{x_0}^1 g_2(x) dx \\
 &= \int_0^{x_0} x(x_0-1) dx + \int_{x_0}^1 -x_0(1-x) dx \\
 &= (x_0-1) \frac{x_0^2}{2} - x_0 \left[x - \frac{x^2}{2} \right]_{x_0}^1 \\
 &= \frac{x_0^3}{2} - \frac{x_0^2}{2} - x_0 \left[1 - \frac{1}{2} - x_0 + \frac{x_0^2}{2} \right] \\
 &= \frac{x_0^3}{2} - \frac{x_0^2}{2} - \frac{x_0}{2} + x_0^2 - \frac{x_0^3}{2}
 \end{aligned}$$

But the point is we do not have a continuous expression of g throughout the domain 0 to 1. What we have done? We have broken down the problem into 2 sub problems across x naught, if you remember. What we have done? We evaluated g in the earlier problem for the same operator. We evaluated that g of x is nothing, but x multiplied by x naught minus 1 for x lying between 0 and x naught and this is equal to minus 1 minus x x naught for x lying in between x naught and 1.

So, what we do, we put this expression and we break down this integration on the right hand side - $x g dx$ into 2 parts: one from 0 to x naught, we write the solution $g_1 x dx$ plus x naught to 1 $g_2 x dx$. So, **0 to x naught**, we put the lower half solution, integration

0 to x_0 x into $x_0 - 1$ dx plus x_0 to 1, g_2 is $-x_0 + x$ dx .

Now, this is an integration where the running variable is x . So, $x_0 - 1$ is constant. So, $(x_0 - 1) \int_0^{x_0} x \, dx$ that is, x^2 by 2, put the limits, it becomes x_0^2 by 2.

Similarly, here $-x_0$ is constant; it is taken out, then it is $\int_{x_0}^1 x \, dx$. So, we put it x_0 minus x^2 by 2 and then evaluate between x_0 and 1. If you do that, let us see what you get? This is x_0^3 by 2 minus x_0^2 by 2 minus x_0 ; put the limit, 1 minus half minus x_0 plus x_0^2 by 2.

(Refer Slide Time: 36:50)

$$\begin{aligned}
 g(x|x_0) &= x(x_0 - 1) \text{ for } 0 \leq x \leq x_0 \\
 &= -(1 - x)x_0 \text{ for } x_0 \leq x \leq 1 \\
 u(x_0) &= \int_0^1 x g(x) dx = \int_0^{x_0} x g_1(x) dx + \int_{x_0}^1 x g_2(x) dx \\
 &= \int_0^{x_0} x^2(x_0 - 1) dx + \int_{x_0}^1 -x_0(1 - x) dx \\
 &= (x_0 - 1) \frac{x^3}{3} \Big|_0^{x_0} - x_0 \left[x - \frac{x^2}{2} \right] \Big|_{x_0}^1 \\
 &= \frac{x_0^3}{3} - \frac{x_0^3}{3} - x_0 \left[1 - \frac{1}{2} - x_0 + \frac{x_0^2}{2} \right] \\
 &= \frac{x_0^3}{3} - \frac{x_0^3}{3} + \frac{x_0}{2} - x_0^2 + \frac{x_0^3}{2}
 \end{aligned}$$

So, we will be getting x_0^3 by 2 minus x_0^2 by 2 minus, this will be half, so, x_0 by 2, minus, minus - plus x_0^2 by 2, minus, plus - minus x_0^3 by 2; x_0^3 will be cancelling out. So, this will be gone. **and then what we will be having is that u of x_0 is equal to then** There is a x there. So, it should be multiplied by x here; it should be multiplied by x there.

So, we put g_1 is equal to x into $x_0 - 1$, x should be multiplied. So, there will be x^2 here; it should be multiplied by x . So, I redo the rest of the calculation once again.

This is not correct. So, we do it once again. I missed a x here. **So x should be** Because this x is there; x times g. When I put the lower half solution, it will be x g 1, x g 2. g 1 – so, x into x naught minus 1. So, it will be x square into x naught minus 1, x into g 2 – so, x naught into 1 minus x multiplied by x.

(Refer Slide Time: 37:48)

The image shows a handwritten derivation for $u(x_0)$ on a blue background. The steps are as follows:

$$\begin{aligned}
 u(x_0) &= \int_0^{x_0} (x_0 - 1) x^2 dx - x_0 \int_{x_0}^1 (x - x^2) dx \\
 &= (x_0 - 1) \frac{x_0^3}{3} - x_0 \left[\frac{x^2}{2} - \frac{x^3}{3} \right]_{x_0}^1 \\
 &= \frac{x_0^4}{3} - \frac{x_0^3}{3} - x_0 \left[\frac{1}{2} - \frac{1}{3} - \frac{x_0^2}{2} + \frac{x_0^3}{3} \right] \\
 &= \frac{x_0^4}{3} - \frac{x_0^3}{3} - \frac{x_0}{6} + \frac{x_0^3}{2} - \frac{x_0^4}{3} \\
 &= x_0^3 \left(\frac{1}{2} - \frac{1}{3} \right) - \frac{x_0}{6} \\
 &= \frac{x_0^3}{6} - \frac{x_0}{6}
 \end{aligned}$$

At the bottom, it says $\Rightarrow x_0 \rightarrow x \Rightarrow u(x) = \frac{x^3}{6} - \frac{x}{6}$.

So, we redo the calculation. u of x naught is equal to integral 0 to x naught x naught minus 1 x square dx minus x naught x naught to 1, this will be, x minus x square dx. Therefore, x naught minus 1 can be taken out. This is x square dx; so, it will be x naught cube by 3. That is how, one will be getting it; minus x naught to be treated as common. It will be 1 by x square by 2 xdx minus x square dx which is x cube by 3, evaluated from x naught to 1.

So, this becomes x naught to the power 4 by 3 minus x naught cube by 3 minus x naught. Put it 1, 1 by 2 minus 1 upon 3 minus x naught square by 2, minus, minus - plus x naught cube by 3. So, it will be x naught to the power 4 by 3 minus x naught cube by 3 minus 1 by 2 minus 1 upon 3 it will be 1 upon 6 so x naught by 6, minus, minus - plus x naught cube by 2 and this will be minus, plus – minus and so, it will be x naught 4 by 3.

So, we cancel them out. What we get is 1 by 2 minus 1 upon 3 x naught cube, **1 by 2 minus 1 upon 3** minus x naught by 6. So, we will be getting x naught cube by 6 minus x naught by 6.

Now, change the running variable from x naught to x . So, you will be getting u of x is equal to x cube by 6 minus x by 6. So, that gives a demonstration how the problem can be solved. Next, I will take up one example, where both the boundary conditions are not homogeneous; they are non-homogeneous. Let us see what we can do about it.

(Refer Slide Time: 41:10)

Ex 3

$$\frac{d^2 u}{dx^2} = x \quad \text{①} \quad \begin{array}{l} \text{at } x=0, u=1 \\ \text{at } x=1, u=2 \end{array}$$

$$\frac{d^2 g}{dx^2} = \delta(x-x_0) \quad \text{②} \quad \begin{array}{l} \text{at } x=0, g=0 \\ \text{at } x=1, g=0 \end{array}$$

$$\int_0^1 g \frac{d^2 u}{dx^2} - \int_0^1 u \frac{d^2 g}{dx^2} = \int_0^1 x g dx - u(x_0)$$

$$g \frac{du}{dx} \Big|_0^1 - u \frac{dg}{dx} \Big|_0^1 = \int_0^1 x g dx - u(x_0)$$

$$g(1) \frac{du}{dx} \Big|_1 - g(0) \frac{du}{dx} \Big|_0 - u(1) \frac{dg}{dx} \Big|_1 + u(0) \frac{dg}{dx} \Big|_0 = \int_0^1 x g dx - u(x_0)$$

d square u so This is example 3. $d^2 u / dx^2$ is equal to x , let us say and at x is equal to 0, u is equal to 1; at x is equal to 1, u is equal to 2.

Now, we formulate the corresponding Green's function $d^2 g / dx^2$ is nothing, but $\delta(x - x_0)$ and at x is equal to 0, we have g is equal to 0; at x is equal to 1, we have g is equal to 0.

Now, there are 3 sources of non-homogeneity in this equation; one is the boundary condition, another is another boundary condition and then one is the governing equation.

If we look into the solution, now, we connect 1 and 2. So, you multiply g with the first equation - $g d^2 u / dx^2$ minus $u d^2 g / dx^2$ is equal to integral $x g dx$ minus $u(x_0)$.

This will be first function. Integral of the second function $g du / dx$ from 0 to 1 minus in fact, that will be cancelling out later on. So, you will be getting one more bi-linear concomitant part from here. $u dg / dx$ at 0 to 1 is equal to integral $x g dx$ minus u of x naught.

Now, we evaluate it g at 1 du/dx at 1 minus g at 0 du/dx at 0 minus u at 1 dg/dx at 1 minus, minus - plus u at 0 dg/dx is equal to at 0 integral $x g dx$ minus u of x naught.

So, we have g is equal to 0 at x is equal to 0; so, this is gone; g is equal to 0 at x is equal to 1; so, this is gone; g is equal to 0 at x is equal to 0; this is gone.

u at 1 is 1; so, we put it at 1, u at x is equal to 1 is 2; so you put at 2 there. u at x is equal to 0 is 1; so, you put a 1 here. Let us see what you get.

(Refer Slide Time: 44:28)

$$-2 \frac{dg}{dx} \Big|_{x=1} + \frac{dg}{dx} \Big|_{x=0} = \int_0^{x_0} x g dx - u(x_0)$$

$$g = \begin{cases} (x_0 - 1)x & \text{for } 0 \leq x < x_0 \\ -x_0(1-x) & \text{for } x_0 < x \leq 1 \end{cases}$$

$$\frac{dg}{dx} \Big|_{x=1} = x_0$$

$$\frac{dg}{dx} \Big|_{x=0} = (x_0 - 1)$$

$$-2x_0 + x_0 - 1 = \int_0^{x_0} x g dx - u(x_0)$$

$$\Rightarrow u(x_0) = (2x_0) + (1-x_0) + \int_0^{x_0} x g dx$$

Then change $x_0 \rightarrow x$ ✓
 $u(x) = \dots$ ✓

So, u of 1 at x is equal to 1 is 2; so, it is 2, minus, dg/dx evaluated at x is equal 1 plus u at x is equal to 0 is 1; so, 1 multiplied by dg/dx evaluated at x is equal to 0 is equal to integral $x g dx$ minus u of x naught.

Now, if you remember, **g 1 is equal to** the expression of g ; g is equal to x naught minus 1 times x , for x lying in between x naught and 0 and is equal to minus x naught into 1 minus x , for x lying in between x naught and 1.

What is dg/dx evaluated at x is equal to 1? That means we are talking about the upper half plane. dg/dx is nothing, but differential of this with respect to x , minus, minus - plus x naught and evaluated at x is equal to 1; dg/dx , x equal to 0 - dg/dx evaluated at x is equal to 0; that means, we are talking about the lower half solution. So, it will be x naught minus 1.

We write here minus $2 \frac{dg}{dx}$ at x is equal 1 is x naught plus $\frac{dg}{dx}$ x is equal to 0 is x naught minus 1 is equal to $\int x g dx$ minus u of x naught. So, if you can observe that there are 3 sources of non-homogeneity in this governing equation of u ; there were 2 non-homogeneities present at the 2 boundaries and one non-homogeneity is present in the governing equation.

So, while 2 terms of the bi-linear concomitant is not 0 and since you will be having a non-homogeneity the governing equation therefore, will be having term which will be an integral; integral means, it is not on the surface; it is occurring throughout the whole bulk of the control volume and there will be 2 non-zero terms; they will be appearing on the surface.

So, 3 sources of non-homogeneity. There will be 3 terms; one can get as a solution of u of x naught. You will be getting u of x naught on the other side; so, we will be getting minus $2x$ naught. This will be plus. You bring it to the other side. minus 1 plus x naught; so, it will be plus. So, 1 will be on the other side it will be plus, x naught will be on the () minus plus that remains same $x g dx$ from 0 to 1.

So, 3 sources of non-homogeneity; we will be having 3 terms here: one term corresponding to one non-homogeneous boundary condition; another term corresponding to another non-homogeneous boundary condition; then the third term which will be corresponding to the integral term which will be corresponding to the non-homogeneous term in the governing equation. So. it will be an integral.

Now, exactly the same way whatever we have done earlier, we break down this problem into 2 sub-problems. We break down this integral into 2 sub integrals; 0 to x naught and x naught to 1 and then put the corresponding equations of x at g and integrate it out. So, you will be getting everything on the right hand side in terms of x naught. Then change the running variable x naught to x and you will be getting a complete solution in terms of u as a function of x . So, that is how the Green's function method is utilized for the solution of partial differential equation and you will be getting the solution soon.

So, these two examples I have taken up the ordinary differential equation for demonstration purpose. Next, I will be taking up the partial differential equation. How to utilize these concepts to get the solution of the partial differential equation, using the

non-homogeneous partial differential equation using the Green's function technique. We have seen and applied these techniques for the ordinary differential equations.

Now, nobody will solve the ordinary differential equation by this method, but it is for demonstration purpose and next, we will be taking up the partial differential equation and apply the Green's function method in order to solve them.

(Refer Slide Time: 49:31)

Parabolic PDE

$$\frac{\partial u}{\partial t} = \frac{\partial^2 u}{\partial x^2} + f(x, t)$$

$$L = \frac{\partial}{\partial t} - \frac{\partial^2}{\partial x^2}$$

Subj. to,

at	$t=0,$	$u=h(x)$
at	$x=0,$	$u=p.$
at	$x=1,$	$u=q.$

Now, let us take up one example. We will be taking up 2 examples: one is the parabolic partial differential equation and another is the elliptic partial differential equations because these types of PDEs are most common in chemical engineering application.

Let us take up a parabolic partial differential equation first. It is $\frac{\partial u}{\partial t}$ is equal to $\frac{\partial^2 u}{\partial x^2}$ plus f of x t .

So, the operator here is $\frac{\partial}{\partial t}$ minus $\frac{\partial^2}{\partial x^2}$. Now, boundary conditions subject to at t is equal to 0, we have u is equal to $h(x)$; at x is equal to 0 we have u is equal to p ; at x is equal to 1, we have u is equal to q .

So, we have taken a general parabolic partial differential equation in 2-dimensional: 1-dimension in time, another dimension in space. $\frac{\partial u}{\partial t}$ is equal to $\frac{\partial^2 u}{\partial x^2}$; this is the non-homogeneous term and if you look into the initial and the boundary condition at t is equal to 0, you have taken everything a non-homogeneous term and non-homogeneous boundary condition. It is a more general boundary condition,

but we have taken the Dirichlet boundary conditions. So, at t is equal to 0, u is equal to h x ; at x is equal to 0, u is equal to p ; at x is equal to 1, u is equal to q

Now, we solve this problem by a method called partial eigenfunction expansion method. I will stop here in this class because this requires a lot of development and some theoretical work should be done before attempting this problem. So, we will be developing the theory of solution of non-homogenous partial differential equation using Green's function method. We develop the theory and then we apply it to the solution of the actual problems.

So, I stop here in this class. Then we take up this problem in the next class for the solution of parabolic partial differential equation by using Green's function method. Thank you very much.
