Solution of non-homogeneous Elliptic PDE

(Contd)

We were looking into the solution of non-homogeneous partial differential equation by using Green's function method. In the earlier class, we looked into a complete solution of a parabolic partial differential equation which was non-homogeneous using Green's function method. Not only that, we looked into what will be the possible solutions, eigenvalues and eigenfunctions in the case of different types of boundary conditions; Neumann Robin mixed, etcetra. We looked into the form of the solution you will be getting.

Elliptic PDE Non-hom.
↳ Steady state with a Source/Sink.

$$\frac{\partial^2 u}{\partial x^2} + \frac{\partial^2 u}{\partial y^2} = f(x,y)$$

f(x) only / f(y) only / const

at $x=0$, $u = u_{01}$
at $x=1$, $u = u_{02}$
at $y=0$, $u = u_{03}$
at $y=1$, $u = u_{04}$

D. B. C. non-hom.

NPTEL

Next, we will be taking up an elliptical partial differential equation. We were told earlier that these types of equations will be occurring in a steady state chemical engineering process with a source or sink.

The governing equation may in general look something like this: $\nabla^2 u = f(x, y)$. This non-homogeneity can be a function of x only, can be a function of y only, it may be a constant or it may be function of x and y both.

We have four boundary conditions - 2 on x and 2 on y because order 2 in both the directions. So at $x=0$, we have $u = u_1$; at $x=1$, we have $u = u_2$; at $y=0$, we have $u = u_3$ and at $y=1$, $u = u_4$.

We have four non-homogeneous boundary conditions and for the time being we make them as Dirichlet boundary conditions. If we do that then we can identify how many sources of non-homogeneities this problem has. This problem has five sources of non-homogeneity - one in the governing equation and four in the four boundary conditions.

(Refer Slide Time: 03:22)

Construction of Causal G.f.

$$\frac{\partial^2 g}{\partial x^2} + \frac{\partial^2 g}{\partial y^2} = \delta(x-x_0) \delta(y-y_0)$$

at $x=0, x=1$ } $\Rightarrow g=0$ ✓ Hom. B.C.

at $y=0, y=1$ } $\Rightarrow g=0$ ✓ Hom. B.C.

If we have this problem, we define this problem the elliptic partial non differential equation then **we will be constructing** next step will be the construction of causal Green's function. In this case the definition of Green's function becomes $\nabla^2 g = \delta(x-x_0) \delta(y-y_0)$.

The non-homogeneous term in the governing equation is substituted by the Dirac delta function and we force all the other boundary conditions to be homogeneous. At x is equal to 0, g is equal to 0 and at x is equal to 1, g is equal to 0. In both the cases since the boundary conditions were Dirichlet; g is equal to 0 on both the boundaries. At y is equal to 0 and y is equal to 1, we have g is equal to 0 since both the boundaries in the y direction of the original problem are Dirichlet boundary condition.

If you see that this equation is having the homogeneous boundary condition in both x direction and both conditions in y directions are homogeneous.

We can have a standard eigenvalue problem independently both in x direction and y direction. We will be using the complete eigenfunction expansion method or full eigenfunction expansion method. If you remember the parabolic problem; we had eigenvalue problem only in the boundary conditions in x direction and in the transient - it has not a boundary value problem, so boundary value problem existed only in x direction. Therefore, we consider a partial eigenfunction expansion method by defining the standard eigenvalue problem in the x direction only among the two independent direction t and x .

In this case, we have standard and independent eigenvalue problem in x direction as well as in y direction because **we have eigenvalue problem in** we have independent eigenvalue problem in both x direction and y direction.

(Refer Slide Time: 05:53)

Full Eigenfunction Expansion Method.

Construction of corresponding Eigenvalue Problem.

$$\frac{\partial^2 \phi_i}{\partial x^2} + \frac{\partial^2 \phi_i}{\partial y^2} + \lambda_i \phi_i = 0$$

at, $x=0, 1 \Rightarrow \phi_i = 0$
 $y=0, 1 \Rightarrow \phi_i = 0$

g in terms of $\phi_i(x, y)$

© CET U.T. KGP

Ex/press NPTEL

Therefore, we will be using the full eigenfunction expansion method for solution to this problem. This method is known as full eigenfunction expansion method. In the case of full eigenfunction expansion method, we construct the corresponding eigenvalue problem.

The construction of corresponding eigenvalue problem will be nothing but $\nabla^2 \phi_i = \lambda_i \phi_i$. Both the boundaries are having the homogeneous conditions. Therefore, the parent problem in Green's function in this the parent problem for this eigenvalue problem is nothing but the Green's function. Since the boundary conditions of the Green's functions are all homogeneous; the eigenfunction and eigenvalue problem ϕ_i must be having homogeneous boundary condition.

That means at x is equal to 0 and 1; we have ϕ_i is equal to 0, at y is equal to 0 and 1; we have ϕ_i is equal to 0. We express our Green's function g in terms of eigenfunctions $\phi_i(x, y)$.

I.I.T. KGP

$$g(x,y) = \sum_i a_i \phi_i(x,y)$$

$$= \sum_m \sum_n a_{mn} \phi_{mn}(x,y)$$

$\phi_{mn} \Rightarrow$ Orthogonal property.

$$g = \sum a_i \phi_i$$

$$a_i = a_{mn} = \frac{\langle g, \phi_{mn} \rangle}{\langle \phi_{mn}, \phi_{mn} \rangle}$$

Make, $\|\phi_i\|^2 = 1 \quad \Rightarrow \quad \frac{\langle g, \phi_i \rangle}{\langle \phi_i, \phi_i \rangle} \quad \|\phi_i\|^2 = 1$

NPTEL

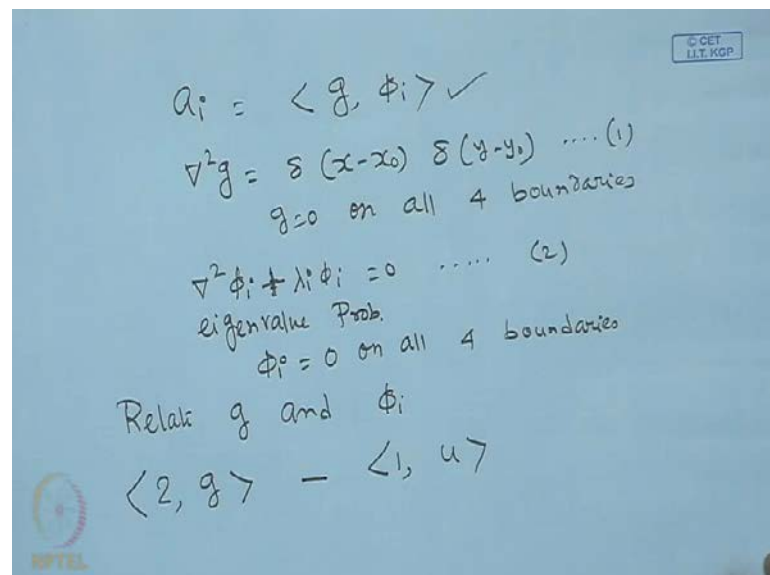

Therefore, g can be written as summation of a_i multiplied by $\phi_i(x, y)$ where i is the summation is over i . In fact, there will be a double summation because we will be having two independent eigen value problem in x direction as well as in y direction; this will be a mn $\phi_{mn}(x, y)$. ϕ_{mn} can be obtained by using the orthogonal property. The constant

a a_n can be obtained; the orthogonal property of the eigenfunction so ϕ_n will obey the orthogonal property of eigen function.

We just write a_n as a_n is equal to summation $a_n \phi_n$, just for the sake of mathematical a_n and handling and writing; we are just replacing the two summation by one summation.

Now, a_n can be evaluated or a_n can be evaluated by taking the inner product of g with respect to ϕ_n or ϕ_n ; $\phi_n \phi_n$. This is because of the orthogonal property of the eigenfunction. This is identical to $g \phi_n$ inner product of ϕ_n and ϕ_n square ϕ_n ; this is nothing but the norm of ϕ_n square.

(Refer Slide Time: 10:39)

What we do is, we evaluate this. We can make this eigenfunction orthonormal; make eigenfunction orthonormal. In that case, the denominator will become 1 and the constant a_n becomes inner product of g and ϕ_n . In order to evaluate this constant what we do is we write down the governing equation grad square g - it is a two dimensional Laplacian operator, so grad square will be nothing but del square del x square plus del square del y square, delta x minus x naught delta y minus y naught, this is equation number 1; subject to g is equal to 0 on all four boundaries.

The next one is grad square ϕ_n plus lambda ϕ_n is equal to 0; this is the eigenvalue problem. This is equation 2; eigenfunction ϕ_n is equal to 0 on all four boundaries.

because Therefore, both the problems g and ϕ_i ; they are homogeneous boundaries everywhere.

(Refer Slide Time: 12:22)

Now, what we do is we relate g and ϕ_i . How to relate g and ϕ_i ? Take inner product of 2 with respect to g , take inner product of 1 with respect to u and then subtract. If you do that then let us see what you get; you will be getting inner product of g grad square ϕ_i , plus $\lambda_i g \phi_i$, minus inner product of grad square $g \phi_i$ minus is equal to minus delta inner product of delta x minus x naught delta y minus y naught, comma ϕ_i .

We will be getting this 1 and then we simplify this equation one after another. This is inner product of g grad square ϕ_i . This λ_i should be written as g inner product of g and ϕ_i , minus inner product of grad square $g \phi_i$; this will be nothing but minus ϕ_i at x naught y naught.

Then we utilize the identity. The identity is grad of u grad v is nothing but grad of u grad of v plus u grad square v ; u grad square v is nothing but grad of u grad v minus grad of u grad of v . We utilize this identity and see what we get out of this terms. This will be nothing but inner product of g grad square ϕ_i dV ; this is a volume integral plus λ_i inner product of g and ϕ_i , minus volume integral ϕ_i grad square g , dV is nothing but minus ϕ_i x naught y naught. We express these two terms by using this identity this identity and see what we get.

(Refer Slide Time: 15:03)

$$\int_V \nabla(g \nabla \phi_i) \, dv - \int_V \nabla g \nabla \phi_i \, dv + \lambda_i \langle g, \phi_i \rangle$$

$$- \int_V \nabla(\phi_i \nabla g) \, dv + \int_V \nabla \phi_i \nabla g \, dv = -\phi_i(x_0, y_0)$$

$$\int_S g \nabla \phi_i \, dS - \int_S \phi_i \nabla g \, dS + \lambda_i \langle g, \phi_i \rangle = -\phi_i(x_0, y_0)$$

On all 4 surfaces, $g=0$ & $\phi_i=0$

$$\langle g, \phi_i \rangle = -\frac{\phi_i(x_0, y_0)}{\lambda_i}$$

If we expand those two integrals in terms of that identity, what we will be getting is that integral gradient of $g \nabla \phi_i \, dv$; this is a volume integral, minus integral grad of $g, \nabla \phi_i \, dv$, plus lambda i inner product of g and ϕ_i , minus volume integral grad of $\phi_i, \nabla g \, dv$, minus minus plus grad of $\phi_i \nabla g \, dv$ is equal to minus ϕ_i at (x_0, y_0) .

If you look into **this** these two terms, they are exactly same and opposite in sign. They will be simply cancelled out. **now integration of** This is called a Green's integral. This is a volumetric integral; this volumetric integral can be converted into surface integral. This will be surface integral - $g \nabla \phi_i \, dS$, minus surface integral $\phi_i \nabla g \, dS$ over the surface, plus lambda i inner product of g and ϕ_i is equal to minus ϕ_i at (x_0, y_0) .

In this case, if you look into this equation to evaluate these surfaces - on all the four surfaces; we have homogenous boundary conditions on g and we have homogenous boundary conditions on ϕ_i

On all 4 surfaces, g is equal to 0 and ϕ_i is equal to 0. Therefore, these two terms will vanish because the values of g and ϕ_i on the surfaces will be equal to 0. Inner product of g and ϕ_i is nothing but minus ϕ_i at (x_0, y_0) divided by lambda i .

(Refer Slide Time: 17:44)

$$g(x,y/x_0,y_0) = - \sum \frac{\phi_i(x_0,y_0) \phi_i(x,y)}{\lambda_i \langle \phi_i, \phi_i \rangle}$$
$$g = - \sum \frac{\phi_i(x_0,y_0) \phi_i(x,y)}{\lambda_i \|\phi_i\|^2}$$

Solve completely the green's function

$$\nabla^2 g = \delta(x-x_0) \delta(y-y_0)$$
$$g=0 \quad \text{on} \quad \left\{ \begin{array}{l} x=0, 1 \\ y=0, 1 \end{array} \right\}$$

So we can We have obtained the inner product between g and ϕ_i . **so if you now write down the expression of Green's function** We can write down the expression of Green's function. g of x, y slash x_0, y_0 is equal to nothing but minus summation ϕ_i of x_0, y_0 , ϕ_i of x, y divided by λ_i ϕ_i of ϕ_i .

So we put the We substitute the inner product of g and ϕ_i by this equation - by this expression, minus ϕ_i of x_0, y_0 divided by λ_i ; this is nothing but norm of ϕ_i . Therefore, **g** expression of g becomes summation ϕ_i of x_0, y_0 , ϕ_i of x, y lambda i norm of ϕ_i square.

Let us **obtain** consider the Green's function method. so **equivalent eigenvalue problem let us solve this** We define this theory for expression of Green's function. For this particular problem, we solve completely the Green's function. Let us obtain the expression of Green's function for this particular problem. $\text{grad}^2 g$ is equal to $\delta(x-x_0)$ $\delta(y-y_0)$ and g is equal to 0 on x is equal to 0 and 1; y is equal to 0 and 1.

On all the four boundaries, we will be having homogenous boundary condition. Let us solve this problem by using the complete eigenfunction expansion method.

(Refer Slide Time: 19:46)

Full eigenfunction Expansion Method.

Linear Homogeneous $\frac{\partial^2 \phi}{\partial x^2} + \frac{\partial^2 \phi}{\partial y^2} + \lambda \phi = 0$ [Corresponding eigenvalue Problem]

at B.C. $\Rightarrow \phi = 0$ at $x=0,1$
 $y=0,1$
 All homogeneous.

Separation of variable.

$\phi = X(x)Y(y)$

$Y \frac{d^2 X}{dx^2} + X \frac{d^2 Y}{dy^2} + \lambda XY = 0$

Use the full eigenfunction expansion method. We will be having del square phi del x square, plus del square phi del y square, plus lambda phi is equal to 0. This is the corresponding eigenvalue problem.

All the eigen the boundary conditions are that on all the four boundaries phi is equal to 0 at x is equal to 0 and 1; y is equal to 0 and 1. phi becomes We use the separation of variable because this equation is linear homogenous boundary conditions; all homogenous. We use the separation of variable method to solve this problem.

(Refer Slide Time: 22:09)

$\frac{1}{X} \frac{d^2 X}{dx^2} + \frac{1}{Y} \frac{d^2 Y}{dy^2} + \lambda = 0$

$\frac{1}{X} \frac{d^2 X}{dx^2} = -\lambda - \frac{1}{Y} \frac{d^2 Y}{dy^2} = -\alpha^2$
 $f(x)$ $g(y)$ \checkmark -ve constant

$\frac{d^2 X}{dx^2} + \alpha^2 X = 0$ sub to $\left. \begin{array}{l} \text{at } x=0, X=0 \\ x=1, X=0 \end{array} \right\}$

$\alpha_n = n\pi, n=1,2,3,\dots$

$X_n = C_1 \sin(n\pi x)$

We assume that ϕ is a product of two functions: capital X which is a function of x and capital Y which is entirely a function of y . We substitute in the governing equation; this will be $Y \frac{d^2 X}{dx^2}$, plus $X \frac{d^2 Y}{dy^2}$, plus λXY is equal to 0. We divide both sides of this equation by XY . What we will be getting is: $\frac{1}{X} \frac{d^2 X}{dx^2}$, plus $\frac{1}{Y} \frac{d^2 Y}{dy^2}$, plus λ is equal to 0.

We write $\frac{1}{X} \frac{d^2 X}{dx^2}$ take λ both the terms on the right hand side; this becomes $-\lambda - \frac{1}{Y} \frac{d^2 Y}{dy^2}$.

If you examine this equation; the left hand side is a function of x alone and the right hand side is a function of y alone. They are equal and they will be equal to some constant and this constant **has to be** can be 0, can be positive and can be negative. We have seen earlier that if this constant is 0 and positive we will be getting a trivial solution but we are looking for non-trivial solution. Therefore, this constant has to be a negative constant.

We will be having $\frac{d^2 X}{dx^2}$, plus $\alpha^2 X$ is equal to 0, subject to, at x is equal to 0 capital X is equal to 0, at x is equal to 1 capital X is equal to 0.

We know the solution to this problem. The eigenvalues of these problems are: $n^2 \pi^2$ where the index n runs from 1, 2, 3; up to infinity and eigenfunctions are $\sin n \pi x$.

(Refer Slide Time: 24:07)

$$-\lambda - \frac{Y''}{Y} = -\alpha^2$$
$$\Rightarrow \frac{1}{Y} \frac{d^2 Y}{dy^2} = (-\lambda + \alpha^2) = -\beta^2$$
$$\Rightarrow \frac{d^2 Y}{dy^2} + \beta^2 Y = 0$$

subject to at $\left. \begin{array}{l} y=0 \\ y=1 \end{array} \right\} \beta=0$

Eigenvalues: $\beta_m = m\pi, m=1, 2, \dots, \infty$

Eigenfunctions: $Y_m = c_2 \sin(m\pi y)$

Let us solve the y dimensional problem - that problem in the y direction. This becomes minus lambda minus Y double prime divided by Y prime Y is equal to minus alpha square. This becomes d square Y dy square, 1 over Y is equal to minus lambda plus alpha square is equal to a constant. Again this constant can be positive, this constant can be negative and this constant can be 0. We have seen earlier that if this constant is 0 and positive, we will be getting a trivial solution. Therefore, this constant has to be a negative constant in order to have an eigenvalue problem.

d square Y dy square plus beta square Y will be is equal to 0, subject to, at y is equal to 0; at y is equal to 1 your beta is equal to 0. You know the solution to this problem. Again, the solution remains the same. **beta m the eigen values** beta m are nothing but m pi where the index m runs from 1 2 infinity and eigenfunctions are Y m is nothing but c 2 sin m pi y. These are the eigenfunctions. We have different subscript m because this is an independent eigenvalue problem.

(Refer Slide Time: 25:59)

Eigen function: $\phi_{mn} = C_{mn} \sin(n\pi x) \sin(m\pi y)$

$$g(x, y | x_0, y_0) = - \sum_{m=1}^{\infty} \sum_{n=1}^{\infty} \frac{\phi_{mn}(x_0, y_0) \phi_{mn}(x, y)}{\lambda_{mn} \|\phi_{mn}\|^2}$$

$$\lambda_{mn} = (m^2 + n^2) \pi^2$$

$$\|\phi_{mn}\|^2 = 1 \quad (\text{Make the eigenfunction orthonormal})$$

$$\iint_{x=0, y=0}^1 C_{mn}^2 \sin^2(n\pi x) \sin^2(m\pi y) dx dy = 1$$

$$x \Rightarrow y \Rightarrow \Rightarrow C_{mn}^2 \underbrace{\int_0^1 \sin^2(n\pi x) dx}_{1/2} \underbrace{\int_0^1 \sin^2(m\pi y) dy}_{1/2} = 1$$

We will be in a position to get the eigenfunction ϕ_{mn} as a function of n and m . We write down the eigenfunction. eigenfunction ϕ_{mn} is nothing but a constant $C_{mn} \sin n \pi x$ and $\sin m \pi y$. We can construct the expression of Green's function. This will be $g(x, y | x_0, y_0)$ is equal to minus - it will be a double summation; 1 index over m and another index over n . Both m and n run from 1 to infinity. This will be $\phi_{mn} \times \phi_{mn}(x_0, y_0)$, $\phi_{mn} \times y \lambda_{mn}$, norm of ϕ_{mn} square. What is λ_{mn} ? λ_{mn} is nothing but λ_{mn} square. **this will be nothing but m square** λ_{mn} is nothing but m square plus n square times π square.

What is ϕ_{mn} square norm of ϕ_{mn} square is equal to 1? We force norm of ϕ_{mn} square is equal to 1 so that the denominator; this term becomes 1 and that simplify our calculations. This means make the eigenfunction orthonormal. If we make the eigenfunction orthonormal, let us see what we get. It will be nothing but double integral $C_{mn}^2 \sin^2 n \pi x, \sin^2 m \pi y, dx dy$ is equal to 1, so x from 0 to 1 and y from 0 to 1. We can carry out this integral since they are in the **product terms** productform, so you can carry out integration independently. $\int_0^1 \sin^2 n \pi x dx$, $\int_0^1 \sin^2 m \pi y dy$ is equal to 1. We have already seen the **half** value of this integral is half so C_{mn} is nothing but 2.

(Refer Slide Time: 29:05)

$C_{mn}^2 = 4 \Rightarrow C_{mn} = 2$
 $\phi_{mn} = 2 \sin(n\pi x) \sin(m\pi y)$
 $g(x, y | x_0, y_0) = -4 \sum_{m=1}^{\infty} \sum_{n=1}^{\infty} \frac{\sin(n\pi x_0) \sin(m\pi y_0) \sin(n\pi x) \sin(m\pi y)}{(m^2 + n^2) \pi^2}$
 ✓
 Adjunct G.F. & Adjunct operator
 $L = \frac{\partial^2}{\partial x^2} + \frac{\partial^2}{\partial y^2}$

C mn square is 4 and C mn is nothing but 2. We get the phi mn as 2 sin n pi x sin m pi y. I get the expression of Green's function now completely. g x y as a function of x naught y naught is nothing but minus 4 double summation 1 over m and another over n. This becomes sin n pi x naught, sin n pi y naught, sin n pi x, sin m pi y divided by m square plus n square pi square.

(Refer Slide Time: 30:58)

$Lg = \frac{\partial^2 g}{\partial x^2} + \frac{\partial^2 g}{\partial y^2}$
 $\langle g^*, Lg \rangle = \int_V g^* \Delta^2 g \, dV$
 $\nabla \cdot (v \sigma u) = v \Delta^2 u + \Delta v \Delta u$
 $\langle g^*, Lg \rangle = \int_V \nabla \cdot (g^* \nabla g) \, dV - \int_V \nabla g \cdot \nabla g^* \, dV$
 $= \int_S g^* \nabla g \cdot \hat{n} \, dS - \int_V \nabla \cdot (g \nabla g^*) \, dV$
 $= \int_S g^* \nabla g \cdot \hat{n} \, dS - \int_S g \nabla g^* \cdot \hat{n} \, dS + \int_V g \Delta^2 g^* \, dV$

We obtain the Green's function now. Next what do we do? We look into the adjoint Green's function and see whether the operator is self adjoint or not. Next, I will take a

diversion; we will look into the adjoint Green's function and adjoint operator. If you look into our operator L , this is a Laplacian $\Delta^2 X^2 + \Delta^2 Y^2$. **so write** Lg is nothing but $\Delta^2 g = \Delta^2 x^2 + \Delta^2 y^2$.

If we evaluate this inner product $g \star Lg$ that is nothing but volume metric integral $g \star \Delta^2 g \, dv$.

Again we utilize the identity, $\text{grad} \, v \cdot \text{grad} \, u$ is nothing but $v \Delta^2 u + \text{grad} \, v \cdot \text{grad} \, u$. We evaluate the inner product of $g \star Lg$ is equal to volume integral $g \star \Delta^2 g$, we just put it as $\text{grad} \, g \star \text{grad} \, g \, dv$, minus volume integral $\text{grad} \, g \cdot \text{grad} \, g \star dv$. **This can be substituted as grad of g** So, utilize this identity **to evaluate this, to simplify** to breakdown this one into two terms; $g \star \Delta^2 g + \text{grad} \, g \cdot \text{grad} \, g$.

What we get is volume integral. We write this as in the form of surface integral. This surface integral becomes $g \star \text{grad} \, g \cdot ds$ **and grad of g** and $\text{grad} \, g \star$ **we obtain** we write it from here. This becomes volume integral of $\text{grad} \, g \cdot \text{grad} \, g \star dv$, minus minus plus, $g \star \Delta^2 g \, dv$. We are utilizing this to simplify this term. We convert the volume integral into surface integral from the first term.

Next, what do we do? We again convert the volume integral into surface integral. What we will be getting is surface integral $g \star \text{grad} \, g \cdot ds$, minus $g \star \text{grad} \, g \cdot ds$, plus volume integral $g \star \Delta^2 g \, dv$.

(Refer Slide Time: 34:44)

$$\langle g^*, Lg \rangle = \int_V g \nabla^2 g^* = \langle L^* g^*, g \rangle$$
$$L^* = \nabla^2 \text{ operator} = \frac{\partial^2}{\partial x^2} + \frac{\partial^2}{\partial y^2}$$
$$L = L^* \quad \&$$

Since the g is having homogenous boundaries on **all the boundary conditions** all the boundaries; this term will vanish. **We make the** We assume the boundary conditions on g^* to be homogenous on all the four boundaries. Therefore, this term will also be vanished. So, bilinear concomitant term is gone. What we will be getting out of this is inner product of $g^* Lg$, is nothing but volume integral $g \nabla^2 g^*$. Therefore, this is nothing but inner product of $L^* g^*$, **comma** g .

What is L^* ? L^* is nothing but the grad square operator that means, by two-dimensional problem this is $\nabla^2 = \frac{\partial^2}{\partial x^2} + \frac{\partial^2}{\partial y^2}$.

(Refer Slide Time: 30:58)

$$Lg = \frac{\partial^2 g}{\partial x^2} + \frac{\partial^2 g}{\partial y^2}$$

$$\langle g^*, Lg \rangle = \int_V g^* \nabla^2 g \, dV$$

$$\nabla(v \nabla u) = v \nabla^2 u + \nabla v \nabla u$$

$$\langle g^*, Lg \rangle = \int_V \nabla(g^* \nabla g) \, dV - \int_V \nabla g \nabla g^* \, dV$$

$$= \int_S g^* \nabla g \, ds - \int_V \nabla(g \nabla g^*) \, dV$$

$$= \int_S g^* \nabla g \, ds - \int_V \nabla g \nabla g^* \, dV + \int_V g \nabla^2 g^* \, dV$$

(Refer Slide Time: 35:45)

$$\langle g^*, Lg \rangle = \int_V g \nabla^2 g^* = \langle L^* g^*, g \rangle$$

$$L^* = \nabla^2 \text{ operator} = \frac{\partial^2}{\partial x^2} + \frac{\partial^2}{\partial y^2}$$

$$L = L^* \quad \& \quad B^* = B$$

$$L^* \rightarrow \text{Self adjoint problem.}$$

Adjoint G.F g^* & writing down gov. Eqn. of g^* & connecting it with u
 — Not necessary

L is equal to L star. We have already seen that B star - in the earlier problem, that in order to make this bilinear concomitant part to be homogeneous, to vanish all the boundary conditions on g star have to be equal to 0 or homogeneous. Therefore, the boundary operator also says that B star is equal to B because the boundary conditions on g star are equal to 0 or homogeneous. The boundary conditions on the g are homogeneous. Therefore, the operator is a self adjoint operator. It is a self adjoint problem. We have B star is equal to B and L star is equal to L.

We need not go for the adjoint Green's function, evaluation of adjoint Green's function g^* , writing down governing equation of g^* and connecting it with u is not necessary for this boundary problem, simply because this elliptical problem **the problem** itself is self adjoint; L is equal to L^* and B is equal to B^* . Therefore, g^* and g will have identical expression, they will have identical boundary conditions and they will have identical governing equation. The last two steps are not required for this particular problem, simply because **the operator** the problem itself is self adjoint problem. We need not go for evaluation of expression of g^* , then writing down the governing equation of g^* and connecting it with u .

We will do that thing which we have done till now. **We can connect** we have already got the expression of Green's function g ; we connect the governing equation of g with the original problem u and can proceed for the solution of the problem. Therefore, let us look into the final solution.

(Refer Slide Time: 38:22)

Final Solution

$$\frac{\partial^2 u}{\partial x^2} + \frac{\partial^2 u}{\partial y^2} = f(x, y) \dots (1)$$

$$\frac{\partial^2 g}{\partial x^2} + \frac{\partial^2 g}{\partial y^2} = \delta(x-x_0) \delta(y-y_0) \dots (2)$$

BC $\Rightarrow u \Rightarrow$ DBC & non-homogeneous
 BC $\Rightarrow g \Rightarrow$ DBC & homogeneous

Inner Product of (1) with g & Inner product of (2) with u & subtract

The final solution is: let us look into the actual problem. $\frac{\partial^2 u}{\partial x^2} + \frac{\partial^2 u}{\partial y^2} = f(x, y)$; this is the original problem.

We write down the Green's function. We need not go for the adjoint Green's function because the **operator** elliptic operator is a self adjoint operator. $\frac{\partial^2 g}{\partial x^2} + \frac{\partial^2 g}{\partial y^2} = \delta(x-x_0) \delta(y-y_0)$. This non homogeneity in the governing equation is replaced by the Dirac delta

function. Boundary conditions on u are Dirichlet and non-homogeneous. Boundary conditions on g are all Dirichlet and homogenous. Therefore, what we do is we connect with this equation 1; this is equation 2.

We take inner product of 1 with g and inner product of 2 with u and subtract. Let us see what we get.

(Refer Slide Time: 40:35)

The image shows a handwritten derivation on a blue background. The equations are as follows:

$$\iint \left(\frac{\partial^2 u}{\partial x^2} + \frac{\partial^2 u}{\partial y^2} \right) g \, dx \, dy - \iint u \left(\frac{\partial^2 g}{\partial x^2} + \frac{\partial^2 g}{\partial y^2} \right) \, dx \, dy$$

$$= \iint f g \, dx \, dy - \iint \delta(x-x_0) \delta(y-y_0) u(x,y) \, dx \, dy$$

$$= \iint f g \, dx \, dy - u(x_0, y_0)$$

Below this, the left-hand side (L.H.S.) is expanded:

$$\text{L.H.S.} = \iint \frac{\partial^2 u}{\partial x^2} g \, dx \, dy + \iint \frac{\partial^2 u}{\partial y^2} g \, dy \, dx$$

$$- \iint u \frac{\partial^2 g}{\partial x^2} \, dx \, dy - \iint u \frac{\partial^2 g}{\partial y^2} \, dy \, dx$$

There are small logos in the corners: '© CET I.I.T. KGP' in the top right and 'NPTEL' in the bottom left.

Double integral del square u del x square plus del square u del y square $g \, dx \, dy$ - that is the first term, minus double integral $u \, \text{del square } g \, \text{del } x \, \text{square plus del square } g \, \text{del } y \, \text{square}; \, dx \, dy$.

That is the left hand side. In the right hand side we have double integral $f \, \text{times } g \, dx \, dy$ minus $\delta x \, \text{minus } x \, \text{naught } \delta y \, \text{minus } y \, \text{naught } u \, x \, y \, dx \, dy$. This will be double integral $f \, \text{times } g \, dx \, dy$ minus $u \, x \, \text{naught } y \, \text{naught}$. That is the right hand side and this is the left hand side. Let us look into the left hand side first and then we will look into the right hand side.

Left hand side; let us see what we get. Left hand side we have $y \, x \, \text{del square } u \, \text{del } x \, \text{square } g \, dx \, dy$ plus $\text{del square } u \, \text{del } y \, \text{square } g \, dy \, dx$ minus $u \, \text{del square } g \, \text{del } x \, \text{square } dx \, dy$ minus $u \, \text{del square } g \, \text{del } y \, \text{square } dy \, dx$. These four terms are present on the left hand side. Next what we do is we carry out the integration by parts. In the first case, we will do the integration with respect to x first then y , do the integration with respect to y

first then x, do the integration of with respect to x first then y, y first then x and see what you get.

(Refer Slide Time: 43:25)

$$\begin{aligned}
 \text{LHS} &= \int_y \left[g \frac{\partial u}{\partial x} \Big|_0^1 - \int_0^1 \frac{\partial g}{\partial x} \frac{\partial u}{\partial x} dx \right] dy \\
 &+ \int_x \left[g \frac{\partial u}{\partial y} \Big|_0^1 - \int_0^1 \frac{\partial g}{\partial y} \frac{\partial u}{\partial y} dy \right] dx \\
 &- \int_y \left[u \frac{\partial g}{\partial x} \Big|_0^1 - \int_0^1 \frac{\partial u}{\partial x} \frac{\partial g}{\partial x} dx \right] dy \\
 &- \int_x \left[u \frac{\partial g}{\partial y} \Big|_0^1 - \int_0^1 \frac{\partial u}{\partial y} \frac{\partial g}{\partial y} dy \right] dx
 \end{aligned}$$

We evaluate the left hand side integral of y. First function g; first function integral so for second function del u del x from 0 to 1 because x varies from 0 to 1, minus differential of first function that is del g del x integration of second one del u del x dx from 0 to 1 dy that is the first one. Second term will be integration over y first; we put the integration of x later on. It will be g del u del y from 0 to 1 minus integral 0 to 1 del g del y del u del y dy and the end we will be having dx minus the third integral that is over x first, y remains same; this becomes u del g del x from 0 to 1 minus integral 0 to 1 del u del x del g del x dx; dy will be outside.

Again, we will be having the 4th term that is minus integration over y first; x will be out. It will be u del g del y from 0 to 1 minus integral 0 to 1 del u del g del y, del u del y and dy dx.

(Refer Slide Time: 45:35)

$$\begin{aligned}
 \text{LHS} &= \int_y (g \frac{\partial u}{\partial x})_0^1 dy - \iint_{yx} \frac{\partial g}{\partial x} \frac{\partial u}{\partial x} dx dy \\
 &+ \int_x (g \frac{\partial u}{\partial y})_0^1 dx - \iint_{xy} \frac{\partial g}{\partial y} \frac{\partial u}{\partial y} dx dy \\
 &- \int_y (u \frac{\partial g}{\partial x})_0^1 dy + \iint_{xy} \frac{\partial u}{\partial x} \frac{\partial g}{\partial x} dx dy \\
 &- \int_x u \frac{\partial g}{\partial y} dx + \iint_{xy} \frac{\partial u}{\partial y} \frac{\partial g}{\partial y} dx dy
 \end{aligned}$$

Next, what we do is we open up these brackets and see what we get. We write down the individual terms. Left hand side is equal to integral over y, g del u del x 0 to 1. This is the whole term times dy minus double integral y x, del g del x, del u del x and dx dy plus integral over x, g del u del y from 0 to 1 dx then minus over x over y, del g del y, del u del y dx dy minus integral over y u del g del x from 0 to 1 dy minus minus plus x y, del u del x, del g del x, dx dy minus integral over x u, del g del y dx; this is from 0 to 1 minus minus plus x y del g del y and del u del y dx dy.

Therefore, if you look into this term; these terms are same, equal and opposite in sign; they will simply cancel out. What will we have? We will have four bilinear concomitant terms and let us evaluate this bilinear concomitant term. Now, g at x is equal to 1, so this term means g at x is equal to one, del u del x at x is equal to 1 minus g at x is equal to 0 and del u del x at x is equal to 0. That simply means, we have the boundary conditions g at 1 and g at 0 is equal to 0; this term will go.

(Refer Slide Time: 48:44)

$$\begin{aligned}
 \text{LHS} &= - \int_{y=0}^1 u(x) \left. \frac{\partial g}{\partial x} \right|_{x=1} dy + \int_{y=0}^1 u(x) \left. \frac{\partial g}{\partial x} \right|_{x=0} dy \\
 &\quad - \int_{x=0}^1 u(x) \left. \frac{\partial g}{\partial y} \right|_{y=1} dx + \int_{x=0}^1 u(x) \left. \frac{\partial g}{\partial y} \right|_{y=0} dx \\
 &= - u_{20} \int_{y=0}^1 \left. \frac{\partial g}{\partial x} \right|_{x=1} dy + u_{10} \int_{y=0}^1 \left. \frac{\partial g}{\partial x} \right|_{x=0} dy \\
 &\quad - u_{40} \int_{x=0}^1 \left. \frac{\partial g}{\partial y} \right|_{y=1} dx + u_{30} \int_{x=0}^1 \left. \frac{\partial g}{\partial y} \right|_{y=0} dx
 \end{aligned}$$

Similarly, if you look into this term $g \text{ del } u$ at y is equal to 1, $\text{del } u \text{ del } y$ at y is equal to 1 minus g at y is equal to 0, $\text{del } u \text{ del } y$ at y is equal to 0. We know the boundary conditions in y direction on g are also homogenous. So g at y is equal to 1 equal to 0, g at y is equal to 0; it is also 0, so this term is gone.

What are these two terms? Only these two terms we will be leaving behind. Let us write down these two terms. More explicitly left hand side is nothing but minus over y - y means from 0 to 1. It is u at 1 $\text{del } g \text{ del } x$ at x is equal to 1; this is x equal to 1, dy minus minus plus, so y is equal to 0 to 1, u at 0 $\text{del } g \text{ del } x$ at x equal to 0 dy . We have minus x is equal to 0 to 1. We have u at x is equal to 1, u at y is equal to 1 and this will be $\text{del } g \text{ del } y$ at y is equal to 1 dx minus minus plus u at y is equal to 0 and $\text{del } g \text{ del } y$ at y is equal to 0 dx and this is from x is equal to 0 to 1.

We already had the non-homogeneous boundary conditions on u . u at 1 is equal to u_1 naught, it will be minus u ; u at x is equal to 0. It was u_1 naught; this is u_2 naught. This is u_2 naught integral y is equal to 0 to 1, $\text{del } g \text{ del } x$ evaluated at x is equal to 1, dy plus u at x is equal to 0; this will be u_1 0 y is equal to 0 to 1, $\text{del } g \text{ del } x$ evaluated at x is equal to 0 dy . We have u at y is equal to 1, so it is u_4 0, x is equal to 0 to 1, $\text{del } g \text{ del } y$ at y is equal to 1 dx plus; this is u_3 0 that will be out. It will be x is equal to 0 to 1 and $\text{del } g \text{ del } y$ at y is equal to 0 dx .

(Refer Slide Time: 51:47)

$$\begin{aligned}
 \text{RHS} &= \iint f g \, dx \, dy - u(x_0, y_0) \\
 \text{LHS} &= \text{RHS} \\
 u(x, y_0) &= \iint_{x=0}^1 \int_{y=0}^1 g \, dx \, dy - u_{10} \int_{y=0}^1 \left(\frac{\partial g}{\partial x} \right)_{x=0} dy \\
 &\quad + u_{20} \int_{y=0}^1 \left(\frac{\partial g}{\partial x} \right)_{x=1} dy - u_{30} \int_{x=0}^1 \left(\frac{\partial g}{\partial y} \right)_{y=0} dx \\
 &\quad + u_{40} \int_{x=0}^1 \left(\frac{\partial g}{\partial y} \right)_{y=1} dx.
 \end{aligned}$$

Left hand side will be having four terms. This four terms will be corresponding to four non-homogeneous terms on the boundary conditions. **If you look into the corresponding equation now let us look into the right hand side this is left hand side and** Let us look into the right hand side; right hand side is nothing but double integral f times g dx dy minus u x $naught$ y $naught$.

What we do, **we take the** we use left hand side is equal to right hand side and we take u x $naught$ y $naught$ on the other side. We put u x $naught$ y $naught$ is equal to integral over x from 0 to 1 and y from 0 to 1. f may be common or if it is a constant function f is taken out. If f is a non-function it can be kept inside and it will be integrated by parts, so g dx dy . This will be minus u 1 $naught$ integral y is equal to 0 to 1, $\text{del } g \text{ del } x$ at x is equal to 0, dy minus minus plus so it will be u 2 $naught$, $\text{del } g \text{ del } x$ at x is equal to 1 dy then it will be minus u 3 $naught$ x is equal to 0 to 1; this is from y is equal to 0 to 1, $\text{del } g \text{ del } y$ at y is equal to 0 times dx minus minus plus u 4 0 x is equal to 0 to 1, $\text{del } g \text{ del } y$ at y is equal to 1 times dx .

You have five terms in the right hand side. If you look into this more carefully, the first term is double integral corresponding to the volumetric integral or non-homogeneous term present in the governing equation. There are four single integral terms or surface integral terms. These four terms corresponds to the four non-homogeneities present on the boundary.

What I will do is I will stop the class at this point and I will take this up in the next class and solve atleast couple of these integrals analytically in order to demonstrate how to solve this problem completely. Once, we are able to solve these problems completely that will give you a complete demonstration of solution of elliptical partial differential equation non-homogenous using the Green's function method.

I will take up this problem in the next class. Thank you very much for your kind attention.
