Vectors

Well good morning everyone. So, we will be starting whatever we have done left in the last class. We were discussing about the properties of the vectors and in the last class we have seen what is called the independent set of vectors, dependent set of vectors, dimension definition of dimension of space.

So, we start from that point onwards, in this class. The dimension of the space is basically, if there are n number of independent vectors present in the vectors or function that is present in the space, then every n plus 1 n th vector or function can be expressed as a linear combination of all this independent vectors. So, then, the dimension of this space is called it is n -dimensional space; for example, if we have a three-dimensional space then there will be existing 3 vectors which are independent and any fourth vector **can be**, will be dependent and it can be expressed as a linear combination of all these three independent vectors.

(Refer Slide Time: 01:25)

Ex1: Consider R^3 space (3 dim. space)

$$e_1 = \begin{bmatrix} 1 \\ 0 \\ 0 \end{bmatrix}; \quad e_2 = \begin{bmatrix} 0 \\ 1 \\ 0 \end{bmatrix}; \quad e_3 = \begin{bmatrix} 0 \\ 0 \\ 1 \end{bmatrix}$$

$\{e_i\} \rightarrow$ independent set of vectors.

$$d_1 e_1 + d_2 e_2 + d_3 e_3 = 0$$

if and only if, $d_1 = d_2 = d_3 = 0$

n th vector can be expressed as a linear combination of $\{e_i\}$.

$$e_4 = \begin{pmatrix} 2 \\ 7 \\ 29 \end{pmatrix}$$
$$e_4 = 2e_1 + 7e_2 + 29e_3$$

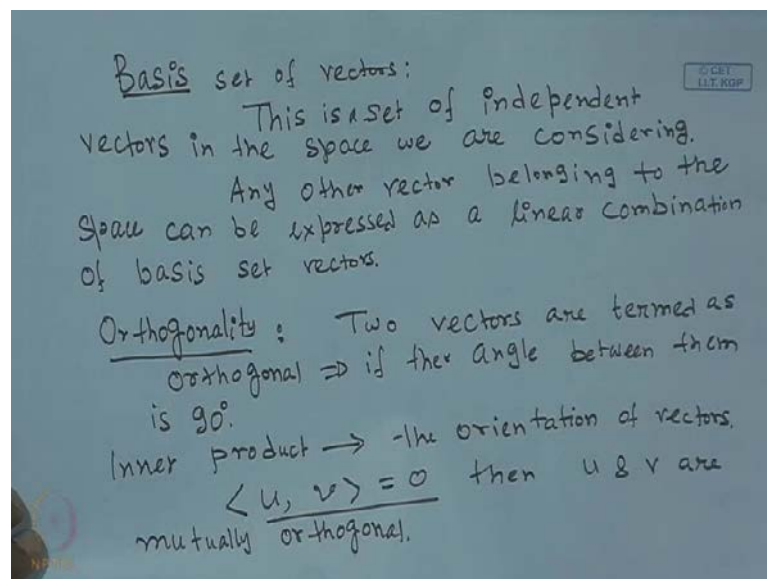

$\{e_1, \dots, e_n\} \Rightarrow$ Dependent set of vectors.

Now, in this class we will just first look into a one example; that let us consider an \mathbb{R}^3 space, it is basically a three-dimensional space where if the vectors $e_1 = \begin{bmatrix} 1 \\ 0 \\ 0 \end{bmatrix}$, $e_2 = \begin{bmatrix} 0 \\ 1 \\ 0 \end{bmatrix}$ and $e_3 = \begin{bmatrix} 0 \\ 0 \\ 1 \end{bmatrix}$; these set of vectors three vectors will constitute an independent set of vectors; so, $\alpha_1 e_1 + \alpha_2 e_2 + \alpha_3 e_3 = 0$.

If and only if the coefficients α_1 , α_2 and α_3 all are identically equal to 0; therefore, these three vectors are called the independent vectors, any other vector, any fourth vector in the space, any other vector can be expressed as a linear combination of these three vectors e_1 , e_2 and e_3 , fourth vector can be expressed as a linear combination of independent set of vectors.

So, for example, if you talk about a fourth vector $e_4 = \begin{bmatrix} 2 \\ 7 \\ 29 \end{bmatrix}$, I mean anything then e_4 can be expressed as a linear combination of these three vectors $2e_1 + 7e_2 + 29e_3$. So, any set constituting the vectors e_4 , e_5 are up to e_n , they will constitute a dependent set of vectors.

(Refer Slide Time: 04:10)

So, next we talk about something called basis of vector or basis set; it is very important, basis set of vectors: this is a set of set of independent vectors in the space we are considering.

So, therefore, the constituent of the basis set vectors are all independent vectors; so any other vector **a** in that space can be expressed as a linear combination of basis set vectors - that is very important.

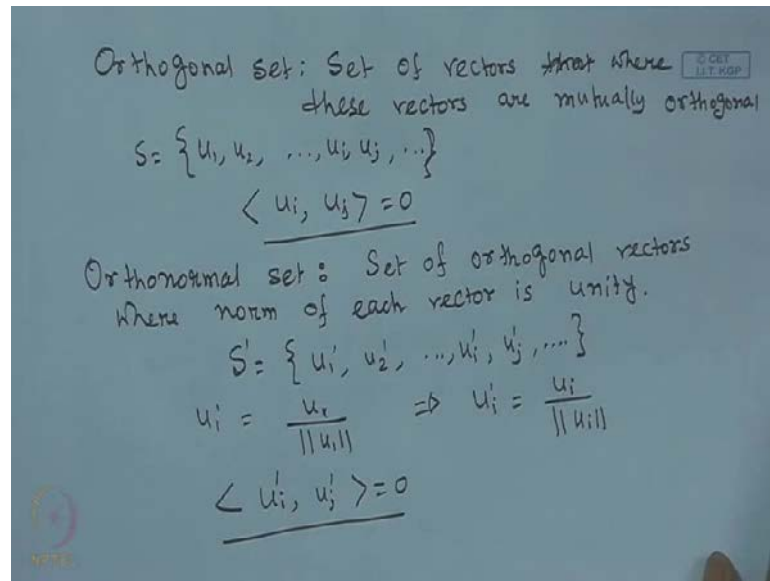

Any other vector belonging to the space can be expressed as a linear combination of basis set vectors. Then we talk about some of the important properties called orthogonality of the vectors: two vectors are termed as orthogonal, if they are perpendicular to each other, that means, the orientation the angle between the two vectors is 90 degree.

So, two vectors are termed as orthogonal, if the angle between them is 90 degree. In other words, if you look into the property of the vector, which will be responsible to indicate the orientation of the two vectors, **it** is the inner product. So, this has a direct implication of the inner product of the two vectors, because inner product indicates the orientation of vectors and if you remember the inner product is nothing but the dot product of the two vectors.

So, the dot product of two vectors is nothing but the magnitude of the individual product, **of** the magnitude of the individual vectors multiplied by the cosine theta or theta is the angle between them.

So, if the angle is 90 degree then cosine 90 is 0. Therefore, the inner product will be turning out to be 0, that means, if inner product between two vectors u and v is equal to 0 then u and v are mutually orthogonal.

(Refer Slide Time: 08:07)

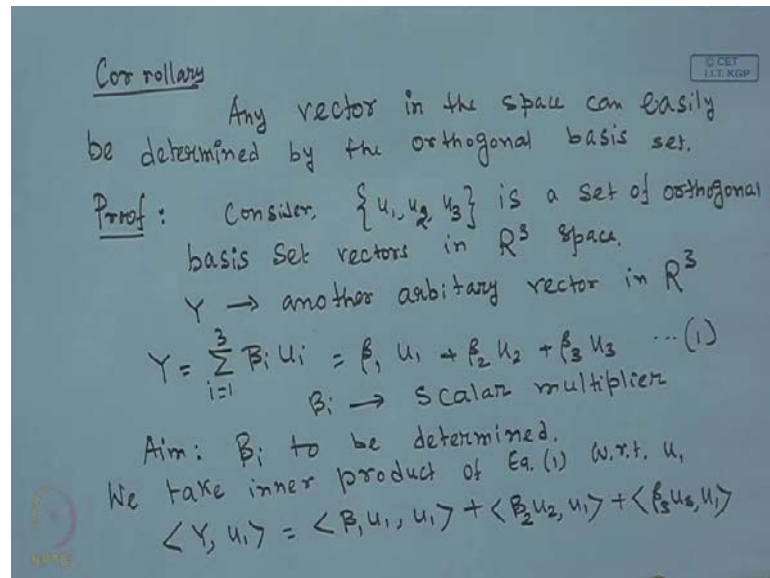

Therefore, this equation gives **a** criteria of orthogonality of the vector. Now, what is the orthonormal set; so what is a orthogonal set of vectors? The orthogonal set, **is a set of**, set of vectors where these vectors are mutually orthogonal; that means, this is a set, this set will be is constituted by u_1, u_2, u_i, u_j , like that; so, for any two vectors, the inner product of the two vectors will be equal to 0; then, these set of vectors is called mutually they constitute orthogonal set. Then, next one is orthonormal set; again, in this case, this is a set of orthogonal vectors where norm of each vector is unity, that means, we are talking of the set, **the earlier set**, it may be a different set, s prime which one is nothing but u_1 prime, u_2 prime, u_i prime, u_j prime, like that; so, u_1 prime is nothing but u_1 divided by norm of u_1 ; so, we make sure that the norm of these vector will be unity.

So, any arbitrary vector will be nothing but u_i divided by norm of u_i and they will be orthogonal to each other, because these vectors are orthogonal to each other; so, inner product between u_i prime and u_j prime will be always equal to 0.

So, the basic criteria to of the vectors which will be form in the orthonormal set is that they will be mutually orthogonal to each other, as well as their norm will be equal to one.

(Refer Slide Time: 10:57)

So, that particular set is termed as orthonormal set. So, what is the **corollary**? The corollary is that any vector in the space where we are working can easily be determined by the orthogonal basis set.

So, if we have any unknown vector in the space that can be expressed as a linear combination of all this independent set of vectors, which are basically the constituent of the basis set and if these vectors are orthogonal to each other, then you will be getting advantage of some of the properties and the whole calculation has been enormously simplified.

We will be just look into this, so let us try to proof this corollary or the interpretation. The proof goes like this, we consider u_1, u_2 and u_3 is a set of orthogonal vectors basis set vectors in R^3 space and so this is a three-dimensional space and we can identify that u_1, u_2, u_3 they are basically mutually independent to each other.

Now, we have Y and arbitrary vector arbitrary fourth vector in same R^3 space, then these vector as the definition of the independent vectors, it will be dependent and it can be expressed as a linear combination of all, in terms of the basis set vector, that means, Y can be expressed as, $\beta_i u_i$ where the index i runs from 1 to 3, so these will be, $\beta_1 u_1$ plus $\beta_2 u_2$ plus $\beta_3 u_3$ and this β_i is are nothing but the scalar multiplier as these are the linear combination.

So, if that is the case, then our aim is to evaluate what are this individual multiplier, so that the any vector in the space can be expressed as a linear combination of the basis set vectors.

So, next is that our aim is that beta i to be determined. How this will be determined, if suppose this is equation number 1, if we take inner product of this equation 1 with respect to e 1, let us see what we get.

So, we take inner product of equation 1 with respect to u 1, let us see what we get; so this is the inner product of u 1 is equal to inner product of beta 1 u 1, u 1 plus inner product of beta 2 u 2, u 1 plus inner product of beta 3 u 3, u 1; so, let us try to simplify this equation.

(Refer Slide Time: 15:06)

Handwritten derivation on a blue background:

$$\langle Y, u_1 \rangle = \beta_1 \langle u_1, u_1 \rangle + \beta_2 \langle u_2, u_1 \rangle + \beta_3 \langle u_3, u_1 \rangle$$

Since $\langle u_2, u_1 \rangle = 0$ and $\langle u_3, u_1 \rangle = 0$ (orthogonal basis), we have:

$$\langle u_1, u_1 \rangle = \|u_1\|^2$$

$$\langle Y, u_1 \rangle = \beta_1 \|u_1\|^2$$

$$\beta_1 = \frac{\langle Y, u_1 \rangle}{\|u_1\|^2}; \quad \beta_2 = \frac{\langle Y, u_2 \rangle}{\|u_2\|^2}$$

$$\beta_3 = \frac{\langle Y, u_3 \rangle}{\|u_3\|^2}$$

If basis set is made by orthogonal - orthonormal vectors $\Rightarrow \|u_1\|^2 = \|u_2\|^2 = \|u_3\|^2 = 1$

So, inner product of Y and u 1 will be nothing but we invoke the property of the inner product that, inner product of alpha x Y is nothing but alpha inner product of x and Y, where x and Y are the two vectors and alpha is the scalar multiplier.

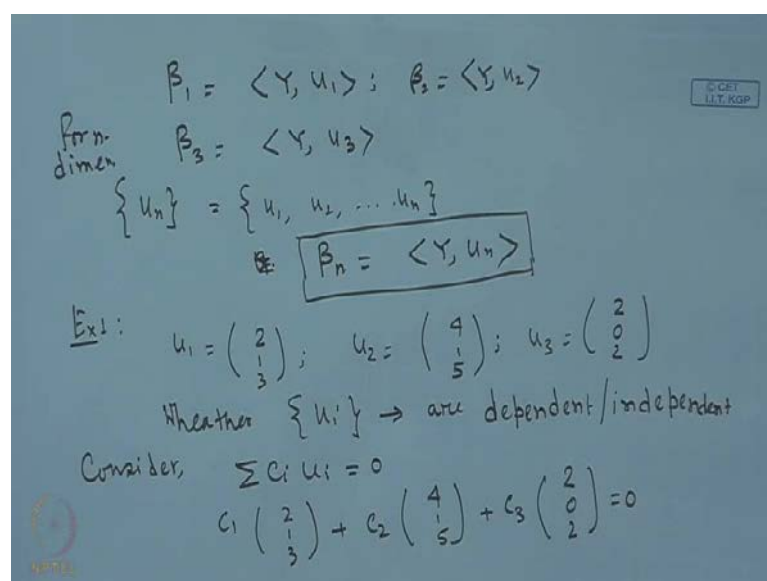

So, therefore, beta 1 can be taken out and it will be inner product of u 1 and u 1 plus beta 2 inner product of u 2 and u 1 plus beta 3 inner product of u 3 and u 1. Now, since use u vector is a set of orthogonal basis set vector, therefore u inner product of u 2 and u 1 will be equal to 0 by definition, because there mutually orthogonal to each other inner product of u 3 and u 1 will be equal to 0.

On the other hand, if you look into this, we can identify in the whatever you have studied in the last class that inner product of u_1 and u_1 is nothing but the norm of u_1 .

So, therefore, this equation boils down to inner product of Y and u_1 is nothing but β_1 norm of u_1 square; so, β_1 can be identified as following quantity inner product of u_1 and Y and u_1 divided by norm of u_1 square.

Similarly, we can identify what is β_2 this is nothing but inner product of Y and u_2 and norm of u_2 square and β_3 is nothing but inner product of Y and u_1 divided by norm of u_3 square. So, if we are considered the basis set is constituted by the orthogonal vectors u_1, u_2, u_3 . Now, if we would have met the basis set is constituted by orthogonal- orthonormal vectors u_1, u_2, u_3 then all these norms would have been equal to one.

(Refer Slide Time: 18:28)

$\beta_1 = \langle Y, u_1 \rangle; \beta_2 = \langle Y, u_2 \rangle$
 $\beta_3 = \langle Y, u_3 \rangle$
 For n -dimen $\{u_n\} = \{u_1, u_2, \dots, u_n\}$
 $\beta_n = \langle Y, u_n \rangle$
 Ex1: $u_1 = \begin{pmatrix} 2 \\ 1 \\ 3 \end{pmatrix}; u_2 = \begin{pmatrix} 4 \\ 1 \\ 5 \end{pmatrix}; u_3 = \begin{pmatrix} 2 \\ 0 \\ 2 \end{pmatrix}$
 Whether $\{u_i\} \rightarrow$ are dependent/independent
 Consider, $\sum c_i u_i = 0$
 $c_1 \begin{pmatrix} 2 \\ 1 \\ 3 \end{pmatrix} + c_2 \begin{pmatrix} 4 \\ 1 \\ 5 \end{pmatrix} + c_3 \begin{pmatrix} 2 \\ 0 \\ 2 \end{pmatrix} = 0$

So, **that**, that simplifies the holder up things; if basis set is made by orthogonal- orthonormal vectors, then it has two simultaneous properties, that in this set the individual vectors are orthogonal, as well as they are norm is equal to 1; that means, u_1 square is equal to norm of u_2 is equal to norm of u_3 square equal to 1; so, in that case, the denominators of all these scalar multipliers will be equal to 1 and the whole thing has been tremendously simplified and you will be getting, β_1 is equal to inner product of Y and u_1 , β_2 is nothing but inner product of Y and u_2 and β_3 is equal to nothing but inner product of Y by u_3 .

If you have n -dimensional space, then let us say, u_n for n dimensional, these for three-dimensional one, for n -dimensional space we can generalize this one that u_n is constituted by n number of basis set vectors, which are mutually orthogonal and orthonormal. Therefore, any i th vector or any n th vector with the coefficients β_n will be expressed as the inner product of Y and u_n ; that means, if Y is a vector that can be in that space, in that n dimensional space, apart from the basis set vectors it can be expressed as a linear combination of all the independent, all the basis set vectors and the corresponding coefficient can be evaluated by taking simply, the inner product of the other vector and the n th vector of the basis set.

So, in this way, we can identify, we can express the a vectors in terms of linear combination of the basis set vectors. So, for that suppose you will be having a basis set vectors, which does not ensure that you will be getting an orthonormal and orthogonal set of vectors.

So, there is a definite method available to convert all the basis set vectors into mutually orthogonal and orthonormal vectors, but before in, before looking into that particular method and technique is known as the Gram-Schmidt Orthogonalization technique, but before going into that, we just look into some of the examples to illustrate the properties of the vectors that whatever we have learnt till now.

So, first example that goes is that, suppose there are three vectors is given u_1 is $\begin{bmatrix} 2 \\ 1 \\ 3 \end{bmatrix}$, u_2 is $\begin{bmatrix} 4 \\ 1 \\ 5 \end{bmatrix}$ and u_3 is $\begin{bmatrix} 2 \\ 0 \\ 2 \end{bmatrix}$; now the point is, question is that whether u_i are dependent or independent?

So, for that, if you, if you considered the equation summation of $c_i u_i$ is equal to 0 then we can obtain the following equations; so that means, $c_1 \begin{bmatrix} 2 \\ 1 \\ 3 \end{bmatrix} + c_2 \begin{bmatrix} 4 \\ 1 \\ 5 \end{bmatrix} + c_3 \begin{bmatrix} 2 \\ 0 \\ 2 \end{bmatrix} = 0$ is equal to 0.

(Refer Slide Time: 22:11)

Handwritten mathematical derivation on a blue background:

$$\begin{aligned} 2c_1 + 4c_2 + 2c_3 &= 0 \quad \dots (1) \\ c_1 + c_2 + c_3 \cdot 0 &= 0 \quad \dots (2) \\ 3c_1 + 5c_2 + 2c_3 &= 0 \quad \dots (3) \end{aligned}$$

$(2) \Rightarrow c_1 = -c_2$

From (1) & (2) $\Rightarrow 2c_2 + 2c_3 = 0 \quad \dots (4)$
 $\checkmark c_2 + c_3 = 0 \quad \dots (4)$

From (2) & (3) $\Rightarrow 2c_2 + 2c_3 = 0$
 $\checkmark c_2 + c_3 = 0 \quad \dots (5)$

$(4) \& (5) \Rightarrow$ identity.
 $c_2 = -c_3$

Infinite number of solutions are possible.

So, let us consider this equation, whether, where the coefficients c_1 , c_2 , c_3 , are all scalar multiplier. So, you will be constituting three equations out of this $2c_1$ plus $4c_2$ plus $2c_3$ is equal to 0.

Then, c_1 plus c_2 plus c_3 multiplied by 0 is equal to 0; and, $3c_1$ plus $5c_2$ plus $2c_3$ is equal to 0. So, this is the first equation, this is equation number 2, this is equation number 3.

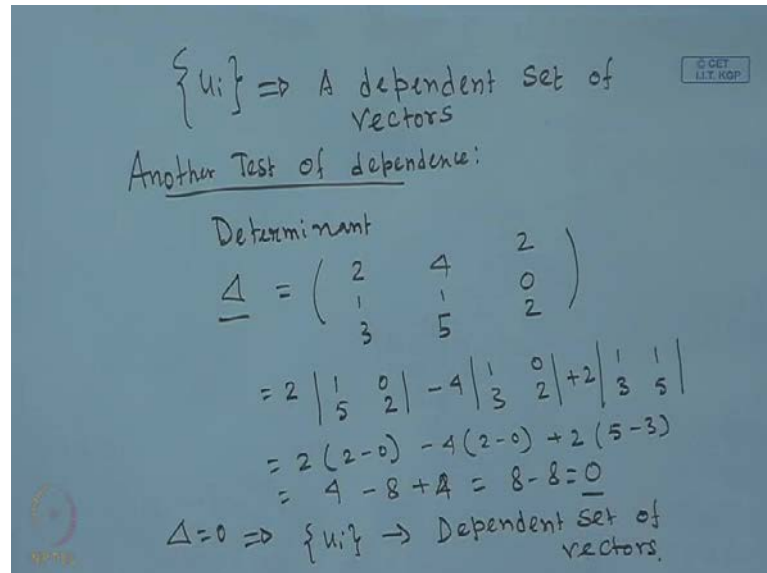

Then, from in, let us try to find out what are the 3 equations 3 unknowns; let us try to find out what are the values of these scalar multipliers c 's. So, from equation 2, we will be getting c_1 is equal to minus c_2 . And, from 1 and 2, if that is the case by combining these two we can get, you just put c_1 equal to minus c_2 , so it will be minus $2c_2$; so, it will be $2c_2$ plus $2c_3$ is equal to 0; this is equation, so you just simplify it further, so it will be divided by two.

So, it will be c_2 plus c_3 is equal to 0 this is equation number 4. Similarly, from equations 2 and 3, what we get is that you express c_1 everything in terms of c_2 substitute c_1 , so it will be minus $3c_2$; so, it will be $2c_2$ plus $2c_3$ will be equal to 0. So, c_2 plus c_3 equal to 0, so this is equation number 5.

So, if you look into, you will be having two equations and two unknowns, but the point is if you look into this equation 4 and 5 they are identical and they represent an identity.

Now, the solution is c_2 is equal to minus c_3 and there will be infinite number of solutions can be present in this system, there will be no definite unique answer.

(Refer Slide Time: 25:03)

$\{u_i\} \Rightarrow$ A dependent set of vectors
 Another Test of dependence:
 Determinant

$$\Delta = \begin{vmatrix} 2 & 4 & 2 \\ 1 & 1 & 0 \\ 3 & 5 & 2 \end{vmatrix}$$

$$= 2 \begin{vmatrix} 1 & 0 \\ 5 & 2 \end{vmatrix} - 4 \begin{vmatrix} 1 & 0 \\ 3 & 2 \end{vmatrix} + 2 \begin{vmatrix} 1 & 1 \\ 3 & 5 \end{vmatrix}$$

$$= 2(2-0) - 4(2-0) + 2(5-3)$$

$$= 4 - 8 + 4 = 8 - 8 = 0$$

$$\Delta = 0 \Rightarrow \{u_i\} \rightarrow \text{Dependent set of vectors.}$$

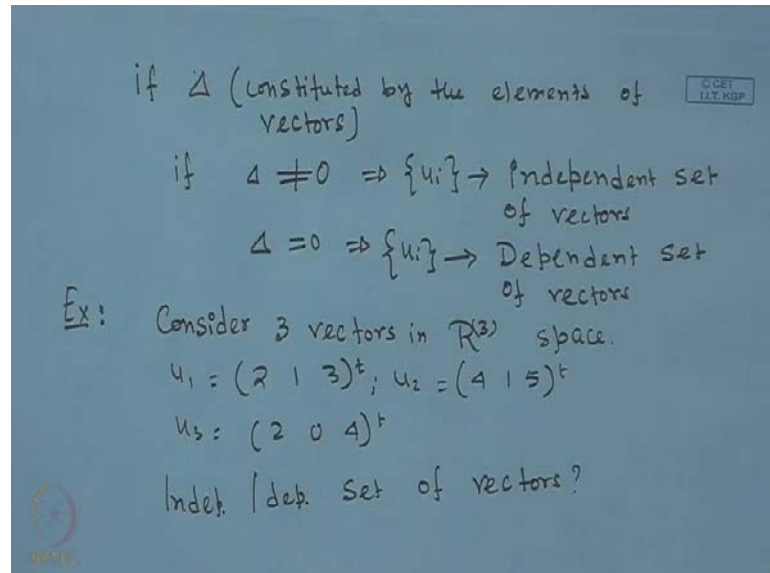

So, infinite number of solutions are possible and therefore these set of vectors are dependent set of vectors, they are no longer independent set of vectors. So, conclusion is u_i constitute a dependent set of vectors. There is another test to check whether the set of vectors are dependent or independent, that test is that we evaluate the determinant produced by these 3 equations; basically, the elements the coefficients of these 3 equations will be the elements of this determinant.

So, if this determinant will be 2 1 3 4 1 5 2 0 2. Now, if you would like to find out what is the value of this determinant, just open up this determinant 2 so it is 1 5 0 2 minus 4 it is 1 3 0 2 plus 2 1 3 and 1 5. So, this becomes 2 multiplied by 2 minus 0 the cross multiplication minus 4 2 minus 0 plus 2 5 into 1 minus 3 into 1. Therefore, this will be 4 minus 8 plus 2 into 2 **is** 4. So, therefore, this will be 8 minus 8 equal to 0.

So, therefore this determinant is equal to 0, if the determinant is equal to 0 then there will be infinite number of solutions present into the set of a equations involving the coefficients c_1 , c_2 , and c_3 . So, this indicates that the basis set vectors, the vectors that we are talking about they constitute a dependent set of vectors.

That is a quick way of evaluating to determine, whether the vectors are dependent or independent.

(Refer Slide Time: 27:44)

So, let us try to summarize whatever we have done; if determinant, the determinants are basically constituted by the elements of vectors; if determine this constituted by the elements of vector.

Now, if determinant is not equal to 0 then vectors constitute independent set. If determinant is equal to 0, then this set of vectors are dependent set of vectors. So, given a problem, we can identify the determinant of the constituted by the corresponding coefficients of the elements of the vector and we can go about it.

Next example, is again for the \mathbb{R}^3 space. These are u_1 is $2 \ 1 \ 3$ transpose, u_2 is $4 \ 1 \ 5$ transpose and u_3 is $2 \ 0 \ 4$ transpose, then we just change the some of the elements, the last element of the last example and you have to check whether they constitute independent or dependent set of vectors; so, we check both the methods and like to determine what is the answer for this problem.

(Refer Slide Time: 30:16)

1st Method: $\sum_{i=1}^3 c_i u_i = 0 \checkmark$

$2c_1 + 4c_2 + 2c_3 = 0 \dots (1)$
 $c_1 + c_2 = 0 \dots (2)$
 $3c_1 + 5c_2 + 4c_3 = 0 \dots (3)$

(1) & (2) $\Rightarrow c_2 + c_3 = 0 \dots (4)$
(2) & (3) $\Rightarrow c_2 + 2c_3 = 0 \dots (5)$

(4) & (5) $\Rightarrow c_3 = 0$
(5) - (4) $\Rightarrow c_2 = 0$
 $c_1 = 0$

$\{u_1, u_2, u_3\} \Rightarrow$ independent set of vectors

Then, let us first method, using the first method, we can express all the vectors as a linear combination of the of the 3 individual vectors, summations $c_i u_i$ and equal to 0. You consider this equation; so, these will be, $2c_1$ plus $4c_2$ plus $2c_3$ is equal to 0, that is equation number 1; then, c_1 plus c_2 equal to 0 that is the equation number 2 and the third 1 will be $3c_1$ plus $5c_2$ plus $4c_3$ equal to 0, that is equation number 3.

So, combining 1 and 2 what we will be getting is that, we will be getting c_2 plus c_3 is equal to 0, as we have already done earlier, but combining 1 and 2 and 3 what we can obtain is that will be getting, c_2 plus $2c_3$ equal to 0, that is equation number 5.

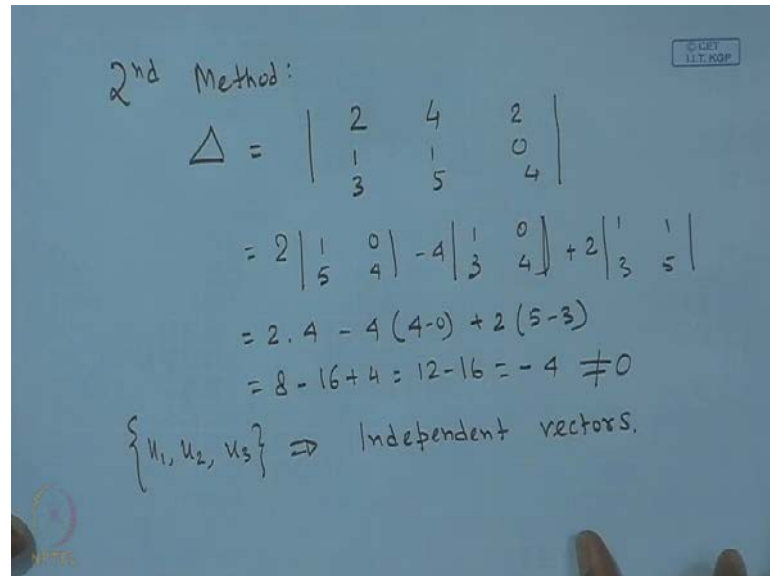

So, if you now combine these 2 equation to solve this 2 unknowns, from 4 and 5 will be getting c_3 , we just subtract 4 from 5, so we subtract 4 from 5, we will be getting c_3 equal to 0 if c_3 equal to 0, then from equation number equation number 4 c_2 will be equal to 0.

If c_2 equal to 0 then from equation number 2, c_1 will be equal to 0. So, in this case, in order to satisfy this equation, all the individual coefficients have to be equal to 0 individually.

So, therefore will be getting a unique solution for this particular case.; they are does not exist an infinite number of solution. In this case, all the individual coefficients scalar multipliers will be equal to 0, in order to satisfy this equation. Therefore, the set

constituted by u_1 , u_2 and u_3 are independent set of vectors; so, that is the conclusion of this analysis.

(Refer Slide Time: 32:54)

Handwritten calculation on a blue background showing the determinant method for vector independence. The text is as follows:

$$\begin{aligned}
 & 2^{\text{nd}} \text{ Method:} \\
 & \Delta = \begin{vmatrix} 2 & 4 & 2 \\ 1 & 1 & 0 \\ 3 & 5 & 4 \end{vmatrix} \\
 & = 2 \begin{vmatrix} 1 & 0 \\ 5 & 4 \end{vmatrix} - 4 \begin{vmatrix} 1 & 0 \\ 3 & 4 \end{vmatrix} + 2 \begin{vmatrix} 1 & 1 \\ 3 & 5 \end{vmatrix} \\
 & = 2 \cdot 4 - 4(4-0) + 2(5-3) \\
 & = 8 - 16 + 4 = 12 - 16 = -4 \neq 0 \\
 & \{u_1, u_2, u_3\} \Rightarrow \text{Independent vectors.}
 \end{aligned}$$

Now, let us look into the method number 2; it is a second method, by looking into the coefficient determinant, so the determinant is constituted by this coefficients that is 2 by this elements, 2 1 3 4 1 5 2 0 4 and these turns out, if you would like to simplify 2 1 5 0 4 minus 4 1 3 0 4 **minus** plus 2 1 3 1 5, **this will be 2 4 minus 0**. So, it will be 2 into 4 minus 4, this will be, 4 minus 0, so it will be 4, plus 2 5 minus 3. So, it will be 8 minus 16 plus 2 into 2 is 4; so, it will be 12 minus 16 is equal to minus 4 and this is not equal to 0, in this particular case. So, therefore, u_1 , u_2 , u_3 , they are independent set of vectors.

(Refer Slide Time: 34:32)

Ex 3: In \mathbb{R}^3 space

$$u_1 = \begin{pmatrix} 3 \\ 2 \\ 1 \end{pmatrix}; u_2 = \begin{pmatrix} 2 \\ -3 \\ 0 \end{pmatrix}; \text{ now}$$

Find out 3rd vector so that $S = \{u_1, u_2, u_3\}$ is a basis set.

Assume, $u_3 = \begin{pmatrix} \alpha_1 \\ \alpha_2 \\ \alpha_3 \end{pmatrix}$ $\alpha_1, \alpha_2, \alpha_3 \rightarrow$ elements of this vector

$$\Delta = \begin{vmatrix} 3 & 2 & \alpha_1 \\ 2 & -3 & \alpha_2 \\ 1 & 0 & \alpha_3 \end{vmatrix}$$

$$= 3 \begin{vmatrix} -3 & \alpha_2 \\ 0 & \alpha_3 \end{vmatrix} - 2 \begin{vmatrix} 2 & \alpha_2 \\ 1 & \alpha_3 \end{vmatrix} + \alpha_1 \begin{vmatrix} 2 & -3 \\ 1 & 0 \end{vmatrix}$$

So, from both the methods we come to the same conclusion. Now, I have another problem example 3, maybe we have two vectors available in a \mathbb{R}^3 space, we have 2 vectors available, u_1 is equal to $\begin{pmatrix} 3 \\ 2 \\ 1 \end{pmatrix}$, u_2 is equal to $\begin{pmatrix} 2 \\ -3 \\ 0 \end{pmatrix}$; so, therefore, these 2 are available and we have to find out third vector in the space; so that, that vectors along with u_1 and u_2 will constitute a basis set vectors so, u_1, u_2, u_3 is a basis set.

Find out the third vector, so that S is a basis set, so that we have **to** two vectors are given, we have to find out the elements of the third vector, such that u_1, u_2 and u_3 constitute the basis set vectors. So, in this problem, first we do not know what is the element of the third vector, therefore, we assume vector number three that is u_3 is nothing but $\alpha_1 \alpha_2 \alpha_3$, where $\alpha_1, \alpha_2, \alpha_3$, are elements of this vector that we are going to determine. If that is the case, then we constitute the corresponding determinant of this problem this will be $3 \begin{vmatrix} -3 & \alpha_2 \\ 0 & \alpha_3 \end{vmatrix} - 2 \begin{vmatrix} 2 & \alpha_2 \\ 1 & \alpha_3 \end{vmatrix} + \alpha_1 \begin{vmatrix} 2 & -3 \\ 1 & 0 \end{vmatrix}$.

So, just evaluate this determinant, if we evaluate this determinant $3 \begin{vmatrix} -3 & \alpha_2 \\ 0 & \alpha_3 \end{vmatrix} - 2 \begin{vmatrix} 2 & \alpha_2 \\ 1 & \alpha_3 \end{vmatrix} + \alpha_1 \begin{vmatrix} 2 & -3 \\ 1 & 0 \end{vmatrix}$, so it will be, $2 \begin{vmatrix} 2 & -3 \\ 1 & 0 \end{vmatrix}$.

(Refer Slide Time: 37:34)

Handwritten mathematical derivation on a blue background:

$$\Delta = 3(-3\alpha_3 - \alpha_2 \cdot 0) - 2(2\alpha_3 - \alpha_2) + \alpha_1(2 \cdot 0 + 3)$$

$$= -9\alpha_3 - 4\alpha_3 + 2\alpha_2 + 3\alpha_1$$

$$= 3\alpha_1 + 2\alpha_2 - 13\alpha_3$$

For independent set of vectors,
 $\Delta \neq 0$

$$3\alpha_1 + 2\alpha_2 - 13\alpha_3 \neq 0 \quad \checkmark$$

For ex: $\alpha_1 = 1, \alpha_2 = 1, \alpha_3 = 1 \Rightarrow -8 \neq 0$

$$u_1 = \begin{pmatrix} 3 \\ 2 \\ 1 \end{pmatrix}; u_2 = \begin{pmatrix} -2 \\ -3 \\ 0 \end{pmatrix}; u_3 = \begin{pmatrix} 1 \\ 1 \\ 1 \end{pmatrix}$$

$\{u_i\} \rightarrow$ Basis set. \checkmark

So, we just keep on simplifying this, so determinant is equal to 3 minus, 3 into alpha 3, so this becomes, 3 alpha 3 minus alpha 2 into 0 minus 2 2 into alpha 3 minus 1 into alpha 2 plus alpha 1 2 into 0, minus **into** minus **plus**, 3 into 1 so it will minus **into** minus plus, so it will be 3.

So, therefore, this becomes minus 9 alpha 3 minus 4 alpha 3 minus 2 alpha 2 plus 3 alpha 1. So, will be getting 3 alpha 1, this will be minus minus, that means, plus, plus 2 alpha 2 minus 13 alpha 3.

Now, in order to get an independent set of vectors, my criteria is that - for independent set of vectors, the criteria is the determinant cannot be equal to 0. Therefore, 3 alpha 1 plus 2 alpha 2 minus 13 alpha 3 should not be equal to 0. Now, we can assume any value corresponding to alpha 1, alpha 2, alpha 3, such that this inequality is satisfied.

For example, if you consider alpha 1 is equal to 1, alpha 2 is equal to 1, alpha 3 is equal to 1, you will be getting 3 plus 2 is 5, 5 minus 13 there is minus 8, minus 8 cannot be equal to 0, it is not equal to 0. Therefore, 1, 1, 1, in along with the other 2 vectors $u_1 \begin{pmatrix} 3 \\ 2 \\ 1 \end{pmatrix}$, $u_2 \begin{pmatrix} -2 \\ -3 \\ 0 \end{pmatrix}$ and $u_3 \begin{pmatrix} 1 \\ 1 \\ 1 \end{pmatrix}$, constitute a basis set vectors are independent set of vectors, that means, u_i is basically a basis set. similarly one could have used any three values of alpha 1, alpha 2, alpha 3, such that this inequality is satisfied not necessary 1, 1, 1, need to be taken; one can take any other combination of alpha 1, alpha 2, alpha 3, but keeping in mind that this inequality has to be satisfied, so that, that vector along with

the first two vectors u_1 and u_2 will constitute a basis set of vectors. So, that indicates how one can determine the dependent and independent set of vectors.

$$Y = \beta_1 \vec{u}_1 + \beta_2 \vec{u}_2 + \beta_3 \vec{u}_3$$
 $\{u_i\} \rightarrow$ Index set vectors.
 $\beta_1, \beta_2, \beta_3$ can easily be determined if $\{u_i\} \rightarrow$ orthogonal basis set.
 \downarrow simplified
 $\{u_i\} \rightarrow$ Orthogonal-orthonormal basis set.

$$\beta_n = \langle \vec{Y}, \vec{u}_n \rangle = \sum_{i=1}^n y_i u_{ni}$$
 Multiplication & addition

Next, we move to the topic on Gram-Schmidt Orthogonalization. As we have said that any fourth vector in the space can be expressed as a linear combination of the 3 basis set vector in \mathbb{R}^3 space of further, but any space it can be expressed as linear combination of the basis set vectors.

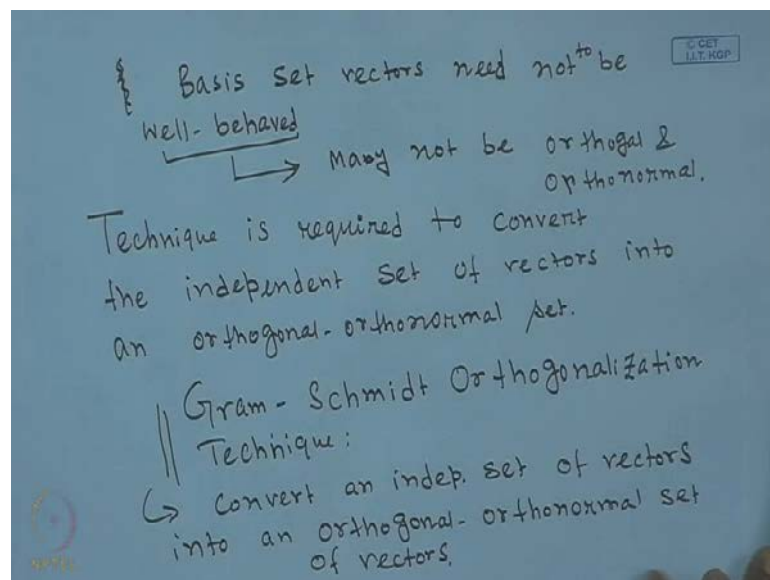

Let us consider, an \mathbb{R}^3 space which will be easy to comprehend; therefore, any fourth vector can be expressed as a function of, **as a**, as a linear combination of the basis set vectors; where u_1 to u_3 , they constitute the independent vectors and we have seen earlier in this class itself, how to find out or determine the coefficients β_1 , β_2 , β_3 , if and only if these basis set vectors are mutually orthogonal to each other. β_1 , β_2 , β_3 , can easily be determined If u_i from the orthogonal basis set. The calculation will become further simplified, if u_i constitute a set of orthogonal - orthonormal basis set.

So, therefore, i am just given example of 3 dimensional space, if you have n-dimensional space then the whole thing becomes very easy. So, the coefficients, if you remember β_n can be expressed as the inner product of Y and n th vector in the space, there is the u_n , so we know this vector, we know this vector, so this will be simply summation of $Y_i u_{ni}$. So, the coefficient can be determined for a larger dimensional problem, by simply you

identify the corresponding elements of this two known vectors and multiply them and then add them up. So, this involves the simple operations like multiplication and addition, so for a larger spaced problem we will write a small program in computer, so that the elements of this 2 vectors, known vectors, will be arranged in an array and we will identify that corresponding i th element of the two vectors will be multiplied and then being added up for all the subsequent terms and the addition will be give you the coefficient β_n .

Similarly, we could be able to put it in a loop and only couple of lines programs you will be able to calculate all the undetermined coefficients β s in this equation.

(Refer Slide Time: 44:30)

But the point is, all the independent set of vectors may not be well behaved set of vectors, that means, basis set vectors need not to be well behaved. What do meant by well-behaved vectors, that means, these vectors may not be orthogonal and at the same time orthonormal.

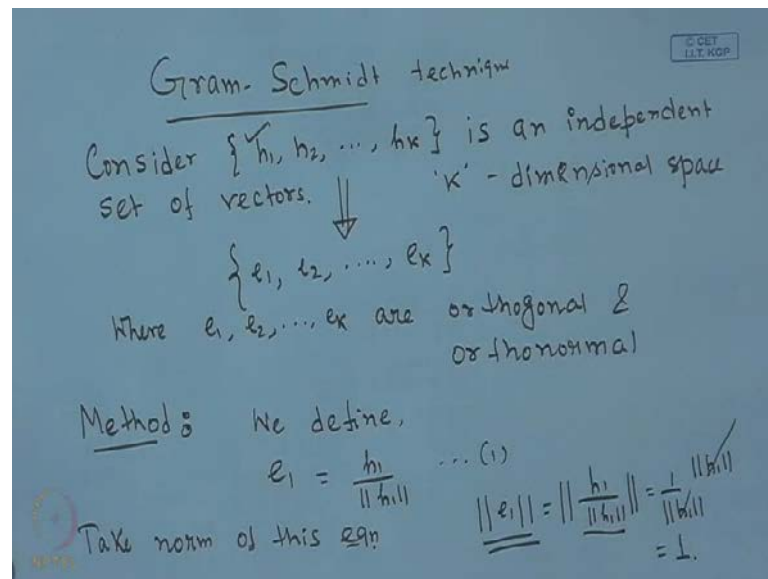

So, for that what you have to do? You have to add up a technique to make the basis set or independent set of vectors to be orthogonal and orthonormal.

So, the mathematical technique is required to convert the independent set of vectors into an orthogonal - orthonormal set; that this particular technique is known as Gram - Schmidt Orthogonalization.

So, by using this technique one can convert an independent set of vectors into an orthogonal - orthonormal set of vectors.

So, next we look into the details, derivation or the technique for getting the Gram-Schmidt Orthogonalization technique.

(Refer Slide Time: 47:25)

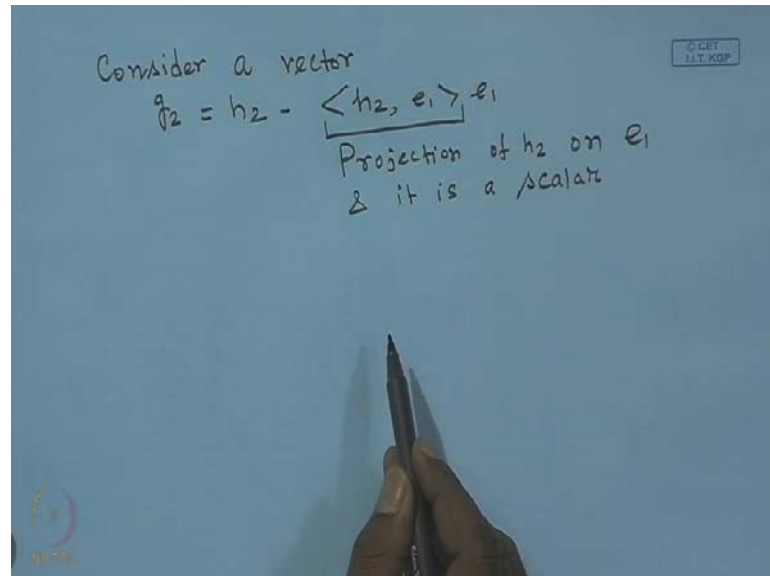

So, let us look into that and see how an independent set of vectors can **we** converted into orthogonal - orthonormal set of vectors. So, for that, let us consider a k dimensional space, where if the set h_1, h_2, h_3 up to h_k is an independent set of vectors; it is basically you are talking about a k dimensional space.

We try, will be getting a set from this set; this set are not orthonormal, so will be getting another independent set of vectors. From these vectors will be getting e_1, e_2 and up to e_k set, where e_1, e_2, e_k are orthogonal and orthonormal both.

So, let us look into the details of this method, so we start with the first vector h_1 , so we define e_1 from this vector itself, such that e_1 is h_1 divided by norm of h_1 . So, if you look into the definition of this vector e_1 , **we can**, we can take the norm of this equation, what will be getting is that you will be getting norm of e_1 is nothing but norm of h_1 divided by norm of h_1 and norm of h_1 is nothing but a scalar, so it comes out of this norm, so it becomes. You just remember the properties of a norm, so this be nothing but norm of h_1 divided by norm of h_1 , this two are the scalars they will be canceling out, so

the magnitude or norm of e_1 turns out to be 1. Therefore, this transformation ensures that the norm of vector e_1 is you will be unity; so, we made the e_1 orthonormal.

(Refer Slide Time: 50:40)

Next, we take consider a vector g_2 , such that g_2 is equal to h_2 minus inner product of h_2 and e_1 multiplied by e_1 . So inner product is a scalar, so it is basically we are formulating a vector **so** which is nothing but the vector h_2 minus some scalar multiplier of the vector e_1 that whatever we have derived just now. So, what is the inner product of h_2 and e_1 physically signifies, it is nothing but a projection of h_2 on e_1 and it is a scalar; so, this is a scalar multiplier.

So, by doing a mathematical operation on this will be going to the next step that will be a stepping stone for formulation of the next vector e_2 of our target set, which will constitute the set of orthogonal an orthonormal basis set. So, will proceed in the next class to complete this formulation, thank you very much.
