Eigenvalue Problem

Good afternoon everyone. So, we will be, as we have discussed in the last class that we have looked into the definitions and various properties of matrices and determinants and looked into so many. We recapitulated some of the old ideas and definitions of whatever we have done earlier years. In our earlier classes, the properties and various properties of the matrices and determinants which will be satisfied.

Classification of different matrices over to which one is called the symmetric matrix, asymmetric matrix, diagonal matrix, skew symmetric matrix, and various properties of them, we have already seen. Now, at the end, we have defined the Eigenvalue problem and Eigenvalues are quite important in all chemical engineering applications.

(Refer Slide Time: 01:13)

$AX = \lambda X$ - λ is a scalar
An eigen value Problem.

$AX - \lambda X = 0$
 $(A - \lambda I)X = 0 \Rightarrow$ Homogeneous Eqn. ... (1)

$(A - \lambda I)X = b \Rightarrow$ Non-homogeneous Eq. ... (2)

For Eq. (1) $\Rightarrow X=0$ is a solution
Known as a trivial solution.

Non-trivial Solution:

So, let us start from that point onward, if we write AX is equal to λX , you have already seen what is the concept of matrix and matrix is nothing but an operator, it

operates on a vector x and it written a value in it maps into X ; so, **it a**, matrix is like a function, it is an operator and if we are able to write the form of the matrix in this particular fashion $A X$ is equal to λX , where λ is a multiplier, is a scalar; we call this problem as an as a standard Eigenvalue problem. So, if you bring $A X$ with the λX on the other side, it becomes $A X$ minus λX is equal to 0; so, we can represent A minus λI should be equal to, multiplied by X , this should be equal to 0; so, therefore this equation is set of a homogenous algebraic equation.

So, this is absolutely homogeneous equation, there is no non-homogeneous term present on the other side. If we have the form of this equation is A minus λI times X is equal to b ; this is a non-homogenous equation. Now, for 1, for equation 1, X is equal to 0 is a solution; **ofcourse**, if X is equal to 0, then that is a solution and this is known as a trivial solution. Therefore, the necessary and sufficient condition for, **not so**, we are not looking for the trivial solution, we are looking for the nontrivial solution.

(Refer Slide Time: 04:09)

The necessary and sufficient conditions for nontrivial solution, is that determinant of A minus λI is equal to 0. Condition for nontrivial solution is determinant of A minus λI is equal to 0. And determinant of this **is**, if A is a square matrix of size n cross n , then this equation will gives you the determinant of A minus λI is equal to 0. This equation gives a polynomial of λ ; finally, it gives a polynomial of λ that is P of λ is equal to 0; degree of the polynomials, this is known as the

characteristic equation; this P of λ is equal to 0 is known as a characteristic equation.

If, for a matrix, square matrix n into n , then the order of this degree of this polynomial is n . So, for n into n matrix, we are talking about n th degree, P of λ is equal to 0 becomes an n th degree of, n th degree polynomial. The roots of this polynomial, roots of this polynomial of P of λ may be real, it may be complex conjugate. So, therefore these roots can occur either a complex conjugate pair and or real valued system and these roots are called Eigenvalues. Eigenvalues of the system and the corresponding solution, the solution corresponding to Eigenvalue is called Eigenvector.

(Refer Slide Time: 07:18)

$\{\lambda_i\} \rightarrow$ a set of eigenvalues
 $\uparrow$ i th eigenvalue $\rightarrow$ corresponding solution is i th eigenvector
 $A X_i = \lambda_i X_i$
 $P(\lambda) = 0$
 For $2 \times 2, 3 \times 3$ matrix eigenvalues are evaluated analytically.
 For higher order systems, numerical solution $\Rightarrow$
 $[\text{HORNER'S Method}] = 0 \quad \underline{\lambda_i}$
 $\text{Givens' Method} \Rightarrow$ eigenvectors.

Suppose, there are λ_i is a set of real valued or complex valued Eigenvalues; i is the, λ_i is the i th Eigenvalue; corresponding to i th value, corresponding solution is known as the i th Eigenvector; solution is i th Eigenvector. So, therefore, in the equation $A X_i$ is equal to $\lambda_i X_i$; so, this will be the solution of the problem corresponding to λ_i , we will be having corresponding to Eigenvalue, will be having the corresponding i th Eigenvector.

Now, if we look into the characteristic equation P of λ is equal to 0. If we are talking about a five, you know five component system, then you will be getting a five into five square matrix and degree of this polynomial will be order will be five; so, therefore you

will you are going to get expect five number of roots from this polynomial or five Eigenvalues.

Now, if it is a 10 into 10 matrix, if A is a 10 into 10 matrix, we are going to get a characteristic equation of degree ten; in that case, there will be ten number of Eigenvalues present in that case. So, if it is a simple system, if it is a 2 into 2 system or 3 into 3 system, the Eigenvalues are quiet; they can be evaluated analytically, for 2 into 2 or 3 into 3 matrix Eigenvalues are evaluated analytically.

For higher order system, we have to take recourse to some numerical techniques, for higher order systems, numerical solution is required. One can take a request to Newton raphson algorithm to find out the first root, then one has to use the some kind of numerical method to evaluate all the Eigenvalues, all the roots of this equation, may be Horner's method may be one of them.

So, by using such numerical technique, one can evaluate all the root of the characteristic equation, P of λ equal to 0; from for the corresponding λ_i one has to evaluate the Eigenvector, may be, Givens' method is there to evaluate the corresponding Eigenvectors.

(Refer Slide Time: 11:15)

So, what are the physical significance of Eigenvalues and Eigenvectors? Eigenvalues are the Eigenvalues and Eigenvectors are basically the characteristic coordinate system.

For example, for a three-dimensional system, like any vector can be represented, as the, along the x axis, along the y axis, along the z axis; so, by the 3 unit vectors, it can be expected. Similarly, for an n-dimensional space, the Eigenvectors will be represented, will represent the mutually orthogonal directions.

So, any vector can be broken down can be resolved into this Eigenvector directions and in these, every Eigenvector direction, the corresponding value, the amplitude will be corresponding to the Eigenvalues, that is the contribution coming up of the original vector the contribution of the vector into the direction of the Eigenvectors will be corresponding, will be represented by the Eigenvalues.

So, therefore, that is the physical significance of Eigenvectors and Eigenvalues. Now there is something called algebraic simplicity. If all Eigenvalues are distinct, they are not repetitive, if all of them are distinct, that means, λ_i they do not occur twice repeatedly. If all the Eigenvalues are distinct, then this is the system is called algebraically simple system.

So, what is an algebraically simple system? A characteristic equation, where all the Eigenvalues are distinct. Then, next we will be proposing will be proving some of the axioms or theorems, which we will be using quite often in our course. So, the first theorem that we are going to prove state and prove, is that, theorem one left Eigenvector of a matrix A is same as right Eigenvector of corresponding matrix transpose matrix A transpose or vice versa.

Now, to prove this thing, let us consider a vector in n-dimensional real space. Consider vector y belongs to n-dimensional real space; so, ofcourse, the transpose vector also belongs to n-dimensional real space.

(Refer Slide Time: 14:52)

Consider Eigenvalue Problem,
 $A (n \times n)$
 $(1 \times n) \leftarrow Y^T$ is left eigenvector of matrix A
 η is corresponding eigenvalue.
Take transpose of Eq. (1)
 $(Y^T A)^T = (\eta Y^T)^T$
 $\Rightarrow A^T (Y^T)^T = \eta (Y^T)^T$
 $\Rightarrow A^T Y = \eta Y$
 $\Rightarrow (A^T - \eta I)Y = 0$ $\Rightarrow$ Eigenvalue Problem
 Y is right eigenvector of A^T . (Proved)

© CET
I.I.T. KGP

Once, we define this vector y and y transposes, then we consider the Eigenvalue problem Y transpose A is equal to η Y transpose; suppose, this equation number one. In this particular equation, Y transpose is left Eigenvector of matrix X and η is corresponding eigenvalue. The size of Y transpose is $1 \times n$, the size of A will be $n \times n$, so since the number of rows number of columns of A matching with the number of rows of Y transpose; therefore, they are confirmable and the matrix multiplication is allowed.

Now, let us take the transpose of equation one; if you take the transpose of equation one, this becomes $Y^T A^T = \eta Y^T$ of that ηY^T transpose of that, you remember we have already taught in the earlier class that, $(AB)^T = B^T A^T$. So, therefore this becomes $A^T (Y^T)^T = \eta (Y^T)^T$ η is being a scalar, so it does not matter; so, it becomes Y^T transpose and transpose of that.

Now, transpose of a transpose matrix is nothing but vector is basically the same one; so, basically $A^T (Y^T)^T = \eta Y^T$. So, again if you look into this equation, this is again an Eigenvalue problem; the form of the equation is again an eigenvalue problem. Here, the corresponding vector is A corresponding matrix is A^T and the Eigenvector is Y . So, Y is Eigenvector, it is basically Eigenvector of A^T and Y is right Eigenvector of A^T , because y is occurring in the right direction, so it will be right Eigenvector of A^T ; so, therefore that completes the proof.

So, we have proof that left Eigenvector of a matrix is nothing but the right Eigenvector of transpose matrix, Y is right at Eigenvector of the transpose matrix; so, we have proved our theorem first theorem.

(Refer Slide Time: 18:43)

Then, we go the next theorem; this theorem says that Eigenvalues of a real matrix is identical to those of transpose matrix. Eigenvalues of a real matrix A are same identical equal to those of A transpose; so, you have to proof that Eigenvalues of A and Eigenvalues of A transpose both are identical.

So, we assume the associated Eigenvalue problem, consider following Eigenvalue problem, will consider a pair of such problems. First one is $A X$ is equal to λX and second one is A transpose Y is equal to ηY ; so, in this case X is the λ , is the Eigenvalues of A . And corresponding Eigenvectors are X , in the second case, in the second problem η are the Eigenvalues of A trans transpose and the Y are the corresponding Eigenvectors.

Now, we **have** already seen that for a matrix from the property of the determinant that determinant of a matrix is equal to the determinant of the transpose matrix. So, therefore we utilize the property for a matrix B , determinant does not change whether the matrix is transpose or normal; so, determinant of B is identical to determinant of B transpose. So, therefore, we write determinant of A minus λI should be equal to determinant of A minus λI transpose.

So, you just consider a matrix A minus λI as B ; so, determinant of the matrix A minus λI is identical to determinant of matrix A minus λI transpose. So, we just open up this transpose operator here, so this becomes determinant of A transpose minus λ being a scalar multiplied by I transpose, but I transpose in essence I is an identity matrix, it remain same.

(Refer Slide Time: 22:51)

$$\det(A - \lambda I) = \det(A^T - \lambda I)$$

Since, $\det(A - \lambda I) = 0$
 $\therefore \det(A^T - \lambda I) = 0 \dots (3) \checkmark$

$Ax = \lambda x \Rightarrow \det(A - \lambda I) = 0$
 $(A^T - \eta I)y = 0 \Rightarrow \det(A^T - \eta I) = 0 \checkmark$
 $A^T y = \eta y$

$$\det(A - \lambda I) = \det(A^T - \eta I)$$

$\Downarrow$

$\lambda = \eta$

Eigenvalues of $A \equiv$ Eigenvalues of A^T
 (Proved)

So, determinant of A transpose minus λI ; so, therefore, from this equation, we can write down that determinant of A minus λI should be is equal to determinant of A transpose minus λI . Now, since determinant of A minus λI is equal to 0, we can, we can say that determinant of A minus A transpose minus λI should also be equal to 0. From this equation determinant of a λ equal to 0; so, therefore determinant of a transpose minus λI should also be equal to 0.

Now, look into equation number two and equation number three, from the equation number three, what we have got. So, whenever we have written that, $A X$ is equal to λX , that simply means, determinant of A minus λI is always 0 and whenever we write A transpose minus ηI is equal to 0 or A transpose Y is equal to ηY this implements determinant of A transpose minus ηI is equal to 0.

So, from this we can compare this equation and this equation; so, if you compare this equation and this equation, what we will get that determinant of A transpose minus

λI is equal to determinant of A transpose minus ηI ; that simply tells us that λ is equal to η .

So, if you remember what is λ ? λ is at the Eigenvalues of the matrix A , η are the Eigenvalues of matrix A transpose, since they are identical; so, we can say that Eigenvalues of matrix A are identical with the Eigenvalues of matrix A transpose; so that completes the proof of the second theorem.

So, we move over to the next theorem and all these theorem are quite useful and helpful for solving the chemical engineering problems, that we will see later on.

(Refer Slide Time: 25:38)

So, next theorem goes like this, this says if Eigenvalues are simple; simple, means, there is no repetition of the Eigenvalues, they are distinct. If Eigenvalues are simple, then Eigenvectors form an independent set of vectors or a basis set. So, that simply, that means, if for the simple Eigenvalues for distinct Eigenvalues, the Eigenvectors form an independent set of vectors of the basis set vectors; that means, **that was**, I was telling in the beginning of this class, that is the physical significance of the Eigenvectors and Eigenvalues.

The Eigenvectors represent individually orthogonal and independent directions, so any vector in the space can be represented as a linear combination of the Eigenvectors; so

that is the physical significance of Eigenvectors and contributions in each direction of the Eigenvectors will be dictated by the corresponding values of corresponding Eigenvalues.

The, let us prove this, that Eigenvectors, they form, they are mutually or independent to each other; so that, they will be form in the independent as if they are represented by the independent axis or this axis will be basically, they are independent directions.

So, the proof goes like this, we assume there are r number of Eigenvectors of a matrix and out of these r Eigenvectors, there are n number of Eigenvectors; in a system there are n number of Eigenvectors and out of these n number of Eigenvectors, out of n Eigenvectors r number of Eigenvectors are independent; that means, rest Eigenvectors from n minus r numbers they are algebraic, they are independent vectors; so, we write X_1, X_2 , up to X_r these are Eigenvectors are independent.

Now, in this notation X_j corresponds to λ_j , that means, for the Eigenvalue λ_j , the corresponding Eigenvector is X_j . So, therefore, for any j lying in between n minus r to n , what is that, all Eigenvectors are independent n minus r or eigenvectors are dependent; that means, any Eigenvectors, so we have said that the total number of Eigenvectors are n out of these n , r number of vectors are independent.

So, what is this set lying in between n minus r and n is this set; that means, it is a dependent set of Eigenvectors. Therefore, any Eigenvectors present in this set it can be expressed as a linear combination of all the independent Eigenvectors X_1, X_2, X_3 , up to X_r .

So, that we have already proved earlier that, any if there are n number of, n number of independent vectors present in a space, any other vector can be represented as a linear combination of these n independent vectors. So, therefore, X_j can be written as a linear combination of all the other independent Eigenvectors and this index i runs from 1 to r , because r number of independent Eigenvectors present in your system; this is equation number one but corresponding C_i must not be equal to 0.

So, why we write this equation? This equation will represents a linear combination of vectors $C_i X_i$ are nothing but the linear combination of vectors. So, this is a dependent vector and X_i is these are all independent vectors.

(Refer Slide Time: 31:34)

$$X_j = \sum_{i=1}^n C_i X_i \quad \dots (1)$$

We operate Eq. (1) by A

$$A X_j = \sum_{i=1}^n A C_i X_i$$

$$A X_j = A C_1 X_1 + A C_2 X_2 + A C_3 X_3 + \dots + A C_r X_r$$

$$A X_j = C_1 A X_1 + C_2 A X_2 + C_3 A X_3 + \dots + C_r A X_r$$

$A X_i = \lambda_i X_i$

$$\lambda_j X_j = A X_j = C_1 \lambda_1 X_1 + C_2 \lambda_2 X_2 + C_3 \lambda_3 X_3 + \dots + C_r \lambda_r X_r$$

$$\lambda_j X_j = C_1 \lambda_1 X_1 + C_2 \lambda_2 X_2 + C_3 \lambda_3 X_3 + \dots + C_r \lambda_r X_r$$

Multiply Eq. (1) by λ_j

$$\lambda_j^2 X_j = C_1 \lambda_j X_1 + C_2 \lambda_j X_2 + C_3 \lambda_j X_3 + \dots + C_r \lambda_j X_r$$

$$0 = C_1 (\lambda_1 - \lambda_j) X_1 + C_2 (\lambda_2 - \lambda_j) X_2 + C_3 (\lambda_3 - \lambda_j) X_3 + \dots + C_r (\lambda_r - \lambda_j) X_r$$

So, let us go to the next step; so, we just open up this equation $C_i X_i$ is equal to 1 to r; we this, let us say equation number 1, we take, we operate this equation by the matrix A. We have already seen earlier that matrix is like a function, it is an operator; so, we operate equation 1 by matrix A, like, it is like differentiation is an operator. We are taking differentiation on both sides; so, it is like, we are taking, we are operating equation 1 by A; so, if that is the case, it will be $A X_j$ is equal to summation of $A C_i X_i$ or i is equal to 1 to r.

Now, we open up this summation series; so, this becomes $A X_j$ is equal to $A C_1 X_1$ plus $A C_2 X_2$ plus $A C_3 X_3$ up to $A C_r X_r$. Now, each of them, so since C_1 is a scalar multiplier, this will be $A X_j$ is equal to $C_1 A X_1$ plus $C_2 A X_2$ plus $C_3 A X_3$ up to $C_r A X_r$. And we have seen we know that $A X_i$ is nothing but $\lambda_i X_i$, that is the standard Eigenvalue problem, for the corresponding value of the λ_i the Eigenvalue, the corresponding Eigenvector is X_i .

So, therefore we can write $A X_j$ is equal to $C_1 A X_1$ is nothing but $\lambda_1 X_1$, so we write $\lambda_1 X_1$ plus $C_2 A X_2$ we write $\lambda_2 X_2$ plus $C_3 A X_3$ is $\lambda_3 X_3$, likewise $C_r A X_r$ is nothing but $\lambda_r X_r$. Now, so that is 1 equation we get, now we multiply equation 1 by λ_j , let us and so we can also write, $A X_j$ as $\lambda_j X_j$; so, we get this equation $\lambda_j X_j$ is equal to $C_1 \lambda_1 X_1$ plus $C_2 \lambda_2 X_2$ plus $C_3 \lambda_3 X_3$ up to $C_r \lambda_r X_r$.

Next, what you do, we multiply equation number 1 with lambda j and see what we get; so, if we multiply equation number 1 by lambda j, we will be getting lambda j times X j is equal to C 1 lambda j X 1 plus C 2 lambda j X 2 plus C 3 lambda j X 3 up to C r lambda j X r; this will be getting by multiplying equation 1 by lambda j, then we subtract this equation from that equation; so, we do a subtraction here and see what we get.

So, if we really do the subtraction, the left hand side will be equal to 0 and let us see what we get in the right hand side, this will be C 1 lambda 1 minus lambda j X 1 plus C 2 lambda 2 minus lambda j X 2 plus C 3 lambda 3 minus lambda j X 3 up to C r lambda r minus lambda j X r.

(Refer Slide Time: 36:21)

$$C_1(\lambda_1 - \lambda_j)x_1 + C_2(\lambda_2 - \lambda_j)x_2 + \dots + C_r(\lambda_r - \lambda_j)x_r = 0 \quad (A)$$

$\lambda_i \neq \lambda_j \quad \lambda_1 - \lambda_j \neq 0$
 $\lambda_2 - \lambda_j \neq 0$

To satisfy Eq. (A),
 $C_1 = 0 = C_2 = C_3 = \dots = C_r$
 $\{C_i\} = 0$

$\{x_1, \dots, x_r\} \Rightarrow$ Form a set of vectors
 we assumed $\{x_1, \dots, x_r\}$ are independent eigenvectors

$x_j = \sum C_i x_i$ where $C_i \neq 0$
 We have proved $\Rightarrow C_i = 0$
 It is contrary to our assumption.

$\{x_j\} \rightarrow n-1$ to n are also
 Independent set of vectors. $\{ \text{All eigenvectors} \} = \text{Independent} \Rightarrow \text{BASIS SET}$

So, let us say, this is equation number 1; so, we get an equation number 1 an equation number a; let us write down equation number a, once again for convenience lambda 1 minus lambda j X 1 plus C 2 lambda 2 minus lambda j X 2 likewise up to C r lambda r minus lambda j X r is equal to 0.

Now, in this equation, we have already, this problem is for algebraically simple problem. So, therefore lambda i is not equal to lambda j; so, therefore lambda 1 is not equal to lambda j, lambda 2 is not equal to lambda j; so, lambda 1 minus lambda j is not equal to 0; so, lambda 1 minus lambda j is not equal to 0.

Similarly, $\lambda_2 - \lambda_j$ is not equal to 0, $\lambda_r - \lambda_i$ is not equal to 0. So, therefore, in order to satisfy this equation A, to satisfy equation A, we must have that all the corresponding coefficients must vanish each and individual; that means, to satisfy equation a compulsorily, we should have C_1 equal to 0, C_2 equal to 0, C_3 equal to 0, up to C_r all of them should be individually equal to 0.

So, therefore, this simply proves that, whatever we have done in the earlier classes, that X_1 for the C_i ; each of this C_i will be equal to 0. Then, X_1 to X_r , they form, they form a set of equations, set of vectors and we have assumed, these are, these are Eigen independent Eigenvectors.

So, therefore, X_j any other vector can be represented as summation $C_i X_i$, where C_i is not equal to 0; so that was our earlier assumption, when we started that we have taken up any Eigenvector from the dependent set lying between j the n and $n - r$, X_j being the, being lying between $n - r$ and n ; so, X_j can be expressed as a linear combination of these vectors; so, therefore we assumed that C_j was not equal to 0, but in this case whatever we have proved that it goes to the contrary of our assumption, that each of them will be individually equal to 0.

So, we have proved that C_i must be equal to 0; so, it contracts, contradicts of our assumption, so it is contrary to our assumption; so, this is called a negative proof. So, what is the implication? The interpretation is that, the rest Eigenvectors the X_j Eigenvectors which a set lying between $n - r$ to n ; they are not dependent set of vectors, they are also independent set of vectors, X_j are also independent set of vectors.

So, therefore, all the Eigenvectors are the independent set of vectors; therefore, all Eigenvectors are independent, all Eigenvectors are independent and they constitute the members, they are the members of the basis set. So, they form a basis set, this completes this proof. So, we have seen that all the Eigenvectors of a matrix A are basically the members of the basis set and basis set vectors any other vector in the space can be represented as a basis set vectors.

So, therefore Eigenvectors of a matrix are always independent, each of them is independent, they are the members of basis set vector. So, any other vector in the space can be represented as a linear combination of all these Eigenvectors.

So, therefore, as we have said a few minutes back, regarding the physical interpretation of the Eigenvectors, that Eigenvectors are nothing but the directions which are mutually independent to each other and any other vector in the space can be represented as a linear combinations of these independent vectors.

(Refer Slide Time: 42:17)

So, next we go to the fourth theorem; theorem number 4, this says Eigenvectors of X , Eigenvectors X_i and X_j corresponds to, if Eigenvectors X_i and X_j correspond to two distinct Eigenvalues λ_i and λ_j ; then if Eigenvectors X_i and X_j correspondent to distinct Eigenvalues; λ_i and λ_j they are orthogonal to each other, for a real symmetric matrix.

For a real, if this is the case, then for a real symmetric matrix X_i and X_j are orthogonal and symmetric matrix, means, A is equal to A transpose. Therefore, if we have, so what is the proposition in this theorem? In this theorem, it is proposed that if we have a real symmetric matrix, that means, A is equal to A transpose then 2 Eigenvectors X_j and X_i they correspond to, if they correspond to two distinct Eigenvalues λ_i and λ_j , then X_i and X_j form an orthogonal set; that means, they are orthogonal to each other.

So, therefore, we proof this theorem and the proof goes like this, let us say λ_i and λ_j are two distinct Eigenvalues, corresponding Eigenvectors are X_i and X_j . And let us write down the associated Eigenvalue problems, with the linked, with the Eigenvalues λ_i and λ_j .

So, we write down the associated Eigenvalue problems, $A X_i$ is equal to $\lambda_i X_i$, this is equation number 1; $A X_j$ is equal to $\lambda_j X_j$, this is equation number 2; these are the associated Eigenvalue problems for λ_i and λ_j . Then what we do, we take the inner product of equation 1 with respect to X_j .

Take inner product of equation 1 with respect to X_j ; if we take the inner product, we will get $X_j^T A X_i$ is equal to inner product of $X_j^T \lambda_i X_i$. So, if we remember that we have proved this equation in the last class, $X_j^T A X_i$ should be $X_j^T A^T X_i$.

So, therefore, so this will be inner product of X_j . And we write it in the other form, we will take that later on, first we take the inner product of equation 1 with respect to X_j and we will be getting equation number 3.

(Refer Slide Time: 47:19)

$$\begin{aligned}
 \langle X_j, A X_i \rangle &= \langle X_j, \lambda_i X_i \rangle \\
 \langle A X_j, X_i \rangle &= \langle \lambda_j X_j, X_i \rangle \\
 \hline
 \langle X_j, A X_i \rangle - \langle A X_j, X_i \rangle &= \lambda_i \langle X_j, X_i \rangle - \lambda_j \langle X_j, X_i \rangle \\
 \langle X, Y \rangle &= X^T Y \\
 X_j^T A X_i - (A X_j)^T X_i &= (\lambda_i - \lambda_j) \langle X_i, X_j \rangle \\
 \text{or } X_j^T A X_i - X_j^T A^T X_i &= (\lambda_i - \lambda_j) \langle X_i, X_j \rangle \\
 0 &= (\lambda_i - \lambda_j) \langle X_i, X_j \rangle
 \end{aligned}$$

On the right side of the slide, there are additional notes: $\langle X, Y \rangle = \lambda \langle X, Y \rangle$, $\langle X_j, X_i \rangle = \langle X_i, X_j \rangle$, and $(AB)^T = B^T A^T$.

Then we take inner product of equation 2 with respect to X_i on the right; so, let us see what we get. Now from these 2, we will be getting, inner product of $X_j^T A X_i$ is equal to inner product of $X_j^T \lambda_i X_i$. Second, the inner product of the second equation with respect to X_i , so $A X_j, X_i$ is equal to inner product of $A X_j$ is nothing but $\lambda_j X_j$ the inner product of $\lambda_j X_j$ and X_i .

Now, we subtract these 2 equations; if you subtract these 2 equations, what we get, it is that inner product of X_j and $A X_i$ minus inner product of $A X_j, X_i$ is equal to we can

take, we invoke the property of the inner product that λ inner product between X and Y is nothing but λ inner product of X and Y , that is, if λ is a scalar; so, similarly, we can take λ_i out, so this becomes X inner product between X_j and X_i minus same here we took λ_j out so it will be λ_j multiplied by inner product of X_j and X_i and we have already proved earlier that inner product of X_j and X_i is identical to inner product of X_i and X_j ; that means, these two are identical and we can write λ_i minus λ_j multiplied take an inner product X_i and X_j can be taken as common.

Then we utilize the formula that whatever we have derived earlier that inner product between X and Y should be is equal to $X^T Y$, that we have already proved probably in the last lecture. So, utilizing that, we will be doing $X_j^T A X_i$ minus $X_j^T A X_i$ is equal to λ_i minus λ_j inner product of X_i and X_j .

So, just open up this transpose, so what we get $X_j^T A X_i$ is nothing but $X_j^T A^T X_i$, we utilize the formula $(AB)^T = B^T A^T$, so $X_j^T A^T X_i$ is equal to λ_i minus λ_j inner product of X_j and X_i .

Now, if you see the quantity on the left hand side is that the left hand side will be having the identical quantities one with the negative sign; so, these 2 will vanish. Now, we have already seen, so what we get from here is that 0 is equal to λ_i minus λ_j inner product of X_i and X_j .

Handwritten derivation on a blue background:

$$\lambda_i \neq \lambda_j$$

$$(\lambda_i - \lambda_j) \langle x_i, x_j \rangle = 0$$

$\neq 0 \quad \Downarrow \quad \langle x_i, x_j \rangle = 0$

$$x_i, x_j \rightarrow \text{are orthogonal}$$

Now, lambda i the Eigenvalues being simple in nature, that means, they are distinct; **distinct**, means lambda i is not is equal to lambda j, they are not repeated roots they are distinct roots. So, therefore, to satisfy this equation inner product of X i and X j should be equal to 0; therefore, so since, lambda is not equal to lambda j, this quantity is not equal to 0; therefore, to satisfy this equation only option left is that inner product of X i and X j must be equal to 0. So, therefore, that simply means, that the Eigenvectors X i and X j are orthogonal.

Handwritten derivation on a blue background:

$$\langle x_j, A x_i \rangle = \langle x_j, \lambda_i x_i \rangle$$

$$\langle A x_j, x_i \rangle = \langle \lambda_j x_j, x_i \rangle$$

$$\langle x_j, A x_i \rangle - \langle A x_j, x_i \rangle = \lambda_i \langle x_j, x_i \rangle - \lambda_j \langle x_j, x_i \rangle$$

$$= (\lambda_i - \lambda_j) \langle x_i, x_j \rangle$$

$\langle x, y \rangle = x^T y$

$$x_j^T A x_i - (A x_j)^T x_i = (\lambda_i - \lambda_j) \langle x_i, x_j \rangle$$

$$x_j^T A x_i - x_j^T A^T x_i = (\lambda_i - \lambda_j) \langle x_i, x_j \rangle$$

$$0 = (\lambda_i - \lambda_j) \langle x_i, x_j \rangle$$

$A = A^T$

$\langle x, y \rangle = x^T y$
 $\langle x_j, x_i \rangle = \langle x_i, x_j \rangle$
 $(AB)^T = B^T A^T$

So, just one more clarification is that, in this equation whenever we are omitting the left hand side, then we are putting the left side is equal to 0; if you look into this equation $X_j^T A X_i - X_i^T A X_j$, but since it is a symmetric matrix A is equal to A^T . Therefore, since A is a symmetric matrix these two quantities become identical and they will be subtracted.

Handwritten notes on a blue background:

$$\lambda_i \neq \lambda_j$$

$$(\lambda_i - \lambda_j) \langle x_i, x_j \rangle = 0 \quad \checkmark$$

$\neq 0 \quad \Downarrow \quad \langle x_i, x_j \rangle = 0$

$x_i, x_j \rightarrow$ are orthogonal

For 3 Dimensional system.

$\lambda_1, \lambda_2, \lambda_3$

x_1, x_2, x_3

for symmetric square matrix,

$$\langle x_1, x_2 \rangle = 0 = \langle x_1, x_3 \rangle = \langle x_2, x_3 \rangle$$

So, therefore this whole left hand side will become 0 and you will be getting this equation; since, λ_i and λ_j are not equal, they are distinct, they will be not equal to 0. So, in order to satisfy this equation, x_i inner product between x_i and x_j must be equal to 0; so, they are orthogonal to each other.

So, therefore if we have three-dimensional system, for three-dimensional system we have three distinct Eigenvalues, λ_1 , λ_2 and λ_3 . Corresponding to three distinct Eigenvalues, you will be having three distinct Eigenvectors x_1 , x_2 , x_3 .

Now, this simply means, that for the symmetric matrix for symmetric square matrix, because Eigenvalue problems are defined on square matrix; only for symmetric square matrix x_1 inner product of x_1 and x_2 is equal to 0, is equal to inner product of x_1 and x_3 and equal to inner product of x_2 and x_3 .

This, simply says that, the Eigenvalue, Eigenvectors are orthogonal to each other, if we have a symmetric matrix; the other is not true that if the matrix is not symmetric that we

cannot say, the Eigenvectors are not orthogonal to each other, that may not be the case, if the matrix is not symmetric. But in that case the Eigenvectors of a matrix A and the Eigenvectors of matrix A transpose they form an orthogonal set.

So, that we will prove in the next class and after that proof we will be able to solve take up any chemical engineering problem and solve them by this Eigenvalue, Eigenvector method.

We stop in this class at here and we will take up from this point onwards, in the next class. Thank you very much.
