

Course on Phase Equilibrium Thermodynamics
By Professor Gargi Das
Department of Chemical Engineering
Indian Institute of Technology Kharagpur
Lecture 11
Tutorial

Hello everybody, so by this time what are the things that we have covered? We have covered the introduction part the first Law and the second law. Before we proceed further I would like to do a few problems on these particular topics and then proceed and the problems which I will be dealing with today, they will be primarily confined to the things which we have already covered and I would also like to mention that the assignments along with these problems will be consulted while preparing the question papers for your final examination.

(Refer Slide Time: 1:03)

(Refer Slide Time: 1:12)

PROBLEM 1

- For $z = z(x,y)$ where x and y are properties of a system, state whether z is also a system property if $dz = xydx + y^2dy$. What functional form between z and x, y will ensure that z is a state function?

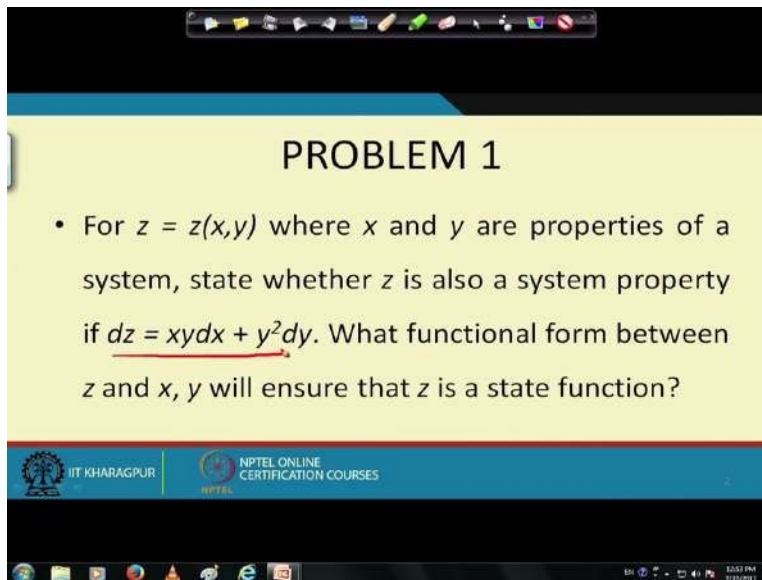

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES

(Refer Slide Time: 1:27)

Now let us go to the first problem here, let us see what the first problem is? The first problem is that, well, there are 3 properties of the system, right? One property is, it can be PVT or anything first property say is z and we have expressed z as a function of 2 other properties x and y just to keep matters general I have mentioned these at z, x and y they can be PVT they can be something, now the thing is that we know that x and y are properties of the system, right?

(Refer Slide Time: 2:08)

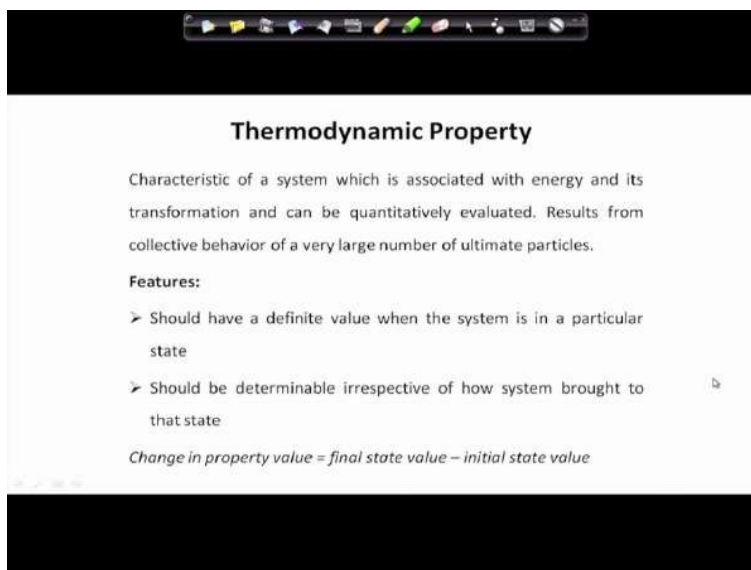

PROBLEM 1

- For $z = z(x, y)$ where x and y are properties of a system, state whether z is also a system property if $dz = xydx + y^2dy$. What functional form between z and x, y will ensure that z is a state function?

The slide is part of an NPTEL online certification course from IIT Kharagpur. It features a yellow background for the problem text and a blue footer with the IIT Kharagpur and NPTEL logos.

And this is the equation of state of the system, the equation of state which relates z with x and y and there is we have mentioned one particular equation of state and what is it given? It is given that whether this particular function form is fine if all the 3 parameters x , y and z have to be properties of the system, how do you go about it? We know that an equation of state relates the different properties of the system.

(Refer Slide Time: 2:34)

Thermodynamic Property

Characteristic of a system which is associated with energy and its transformation and can be quantitatively evaluated. Results from collective behavior of a very large number of ultimate particles.

Features:

- Should have a definite value when the system is in a particular state
- Should be determinable irrespective of how system brought to that state

Change in property value = final state value – initial state value

The slide has a white background with a black header and footer. It defines a thermodynamic property and lists its key features.

How do we define properties? If you recall one of my slides you will see that we had defined properties of the system as the characteristic of a system which is associated with energy and its transformation and we had mentioned a few features of the system, what is it? Firstly it should have a definite value when the system is in a particular state it should be determinable irrespective of how the system is brought to that particular state.

(Refer Slide Time: 3:11)

$$\begin{aligned}
 z &= z(x, y) \\
 dz &= \left(\frac{\partial z}{\partial x} \right)_y dx + \left(\frac{\partial z}{\partial y} \right)_x dy = M dx + N dy \\
 \left[\frac{\partial}{\partial y} \left(\frac{\partial z}{\partial x} \right)_y \right]_x &= \left[\frac{\partial}{\partial x} \left(\frac{\partial z}{\partial y} \right)_x \right]_y \\
 \frac{\partial^2 z}{\partial y \partial x} &= \frac{\partial^2 z}{\partial x \partial y} \Rightarrow \left(\frac{\partial M}{\partial y} \right)_x = \left(\frac{\partial N}{\partial x} \right)_y \\
 \left(\frac{\partial M}{\partial y} \right)_x &= x = \left(\frac{\partial N}{\partial x} \right)_y = y^2 \Rightarrow M = xy^3, N = x^2y^2
 \end{aligned}$$

Or in other words it is independent of the path followed in moving from one state to the other, it depends upon the initial state and the final state. So therefore suppose I write down dz equals to say it is a function of x and y . So it should be $\partial z / \partial x$ at constant y dx plus $\partial z / \partial y$ at constant x dy , right? Now where this should be an exact, since it is an exact differential we can always write it down as $M dx$ plus $N dy$.

Where M is $\partial z / \partial x$ at constant y , N is $\partial z / \partial y$ at constant x . Now suppose we double differentiate this equation, so in that case suppose we are differentiating it in the form $\partial / \partial y$ of $\partial z / \partial x$ at constant y this should be equal to $\partial / \partial x$ of $\partial z / \partial y$ at constant x this is at constant y this is at constant x . It should hardly matter whether we are differentiating z with x first or with y first or in other words both the things $\partial^2 z / \partial y \partial x$ should be equal to $\partial^2 z / \partial x \partial y$, isn't it?

If this has to hold true only then we can say that z is a property of the system, now for this to hold to, what does it imply? It implies that $\partial M / \partial y$ at constant x should be equal to $\partial N / \partial x$ at constant y .

x at constant y. So what do we need to know? The equations which have been proposed in this particular case, the equation is $xydx + y^2 dy$.

So therefore this is nothing but M we have denoted this as M this as N. So what do we require to do in order to find out whether z is a property or z to be a property dz has to be an exact differential, if dz is an exact differential then the order of differentiating z with respect to x and y is not going to matter $\frac{\partial^2 z}{\partial y \partial x}$ should be equal to $\frac{\partial^2 z}{\partial x \partial y}$ and this automatically implies that $\frac{\partial M}{\partial y}$ at constant x should be equal to $\frac{\partial N}{\partial x}$ at constant y.

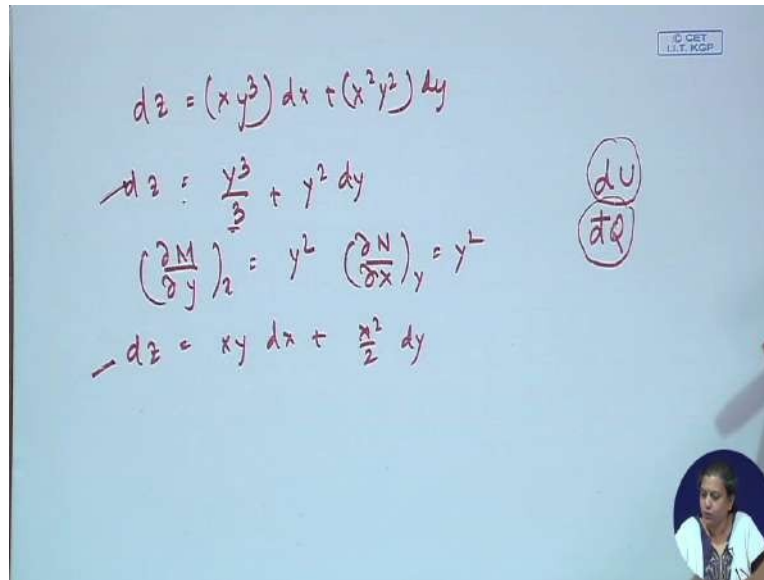

So for the equation of state which is provided, we just need to verify this particular thing. Once we verify this we find that this holds true then we can always say that this particular equation of state is thermodynamically consistent. So let us see what is $\frac{\partial z}{\partial N}$ $\frac{\partial x}{\partial y}$ at constant y under this particular condition? Here we find that $\frac{\partial M}{\partial y}$ at constant x this is nothing but equal to X, right? And what is $\frac{\partial N}{\partial x}$ at constant y this is equal to y^2 .

So therefore we find that this is not equal to this and therefore this is not a proper equation of state or this is not a proper functional form between x, y and z in order to ensure that z is a property. So therefore what is the question? What will be a proper functional form? Now in order to get a proper functional form we need to suggest corrections either in M or in N or in both such that this equation is valid.

Now this can be done in a number of ways for example suppose I suggest or suppose we propose that M is equal to say xy^3 , N is equal to $x^2 y^2$ I have changed both of them. Now for this particular situation what is $\frac{\partial M}{\partial x}$ $\frac{\partial y}{\partial y}$ at constant X let us see? This is nothing but equals to $2xy^2$, let me write it in a different pen, if we propose M equals to xy^3 N equals to $x^2 y^2$.

For that case we find $\frac{\partial M}{\partial y}$ at constant x is going to be $2xy^2$ similarly $\frac{\partial N}{\partial x}$ at constant y is also going to be $2xy^2$. So therefore this can be one particular equation of state relating x, y and z we have obtained this by modifying both the terms.

(Refer Slide Time: 8:10)

$$dz = (xy^3) dx + (x^2y^2) dy$$

$$dz = \frac{y^3}{3} + y^2 dy$$

$$\left(\frac{\partial M}{\partial y}\right)_x = y^2 = \left(\frac{\partial N}{\partial x}\right)_y = y^2$$

$$dz = xy dx + \frac{x^2}{2} dy$$

$\frac{dU}{dQ}$

So therefore a correct equation of state in this case can be $xy^3 dx + x^2y^2 dy$ but please remember this is not the only equation of state that we can use. We can use some other equation of state as well, for example suppose we suggest that dz equals to $y^3/3 + y^2 dy$, what do we get in this particular case? We get $\left(\frac{\partial M}{\partial y}\right)_x = y^2$ and $\left(\frac{\partial N}{\partial x}\right)_y = y^2$. So therefore this can also be an equation of state where we have just modified one term and kept the other term, this term is kept constant only this term has been changed.

In the same way, we can also write it down as say $xy dx + x^2/2 dy$. So this can also be an equation of state, right? So therefore we will find that for any particular property it is important to remember that the differential has to be an exact differential and if you recall I had repeatedly requested you in order to differentiate between exact and inexact differentials. Exact differentials I had shown by d , inexact differentials by a cut d , dQ , dW in this way, du in this way you can very well understand the difference while this depends upon the path this is just a state function. So therefore it's immaterial how we perform this u , it is just important that initial and final states are the same.

(Refer Slide Time: 9:58)

$$z = z(x, y)$$

$$dz = \left(\frac{\partial z}{\partial x}\right)_y dx + \left(\frac{\partial z}{\partial y}\right)_x dy = M dx + N dy$$

$$\left[\frac{\partial}{\partial y} \left(\frac{\partial z}{\partial x}\right)_y\right]_x = \left[\frac{\partial}{\partial x} \left(\frac{\partial z}{\partial y}\right)_x\right]_y$$

$$\frac{\partial^2 z}{\partial y \partial x} = \frac{\partial^2 z}{\partial x \partial y} \Rightarrow \left(\frac{\partial M}{\partial y}\right)_x = \left(\frac{\partial N}{\partial x}\right)_y$$

$$\left(\frac{\partial M}{\partial y}\right)_x = x \quad \left(\frac{\partial N}{\partial x}\right)_y = y^2$$

$$M = xy^2 \quad N = xy^2$$

And the equation of state that cannot be anyone equation of state connecting the 3 variables this can be one equation of state, this can be one equation of state where I have just changed one parameter and along with that this can also be an equation of state, this can also be in equation of state. So therefore this is one thing which I wanted to emphasize upon that how you are going to find out whether any equation of state is thermodynamically consistent or not?

(Refer Slide Time: 10:20)

PROBLEM - 2

- The properties of a certain fluid are related as follows:
 $u = 178 + 0.718t$; $Pv = 0.267(t+273)$
 where u is the ^{specific} internal energy (kJ/kg), t is in °C, P is pressure (kN/m²), v is the specific volume (m³/kg).
- a. For the fluid, find C_v and C_p .
- b. A stationary system consisting of 2 kg of this fluid expands in an adiabatic process according to $Pv^{1.2} = \text{constant}$. The initial conditions are 1 MPa and 200°C and the final pressure is 0.1 MPa. Find W and ΔE for the process. Why is the work transfer not equal to $\int PdV$?

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES

Now let us go to the second problem, what is the second problem? We had expressed internal energy or rather to be more specific it's wrongly written it is the specific internal energy, I am sorry about it. It should be the specific internal energy. So therefore we have an equation relating the specific internal energy with the temperature which automatically suggests us number of things. The first thing is internal energy is a function of temperature only in this particular case and the equation of state for that particular fluid.

(Refer Slide Time: 11:36)

Handwritten notes on a blue background:

$$Pv = C_1 T \quad C_p$$

$$u = f_1(T) \quad C_v$$

$$P_1 = 1 \text{ MPa} \quad P_2 = 0.1 \text{ MPa}$$

$$T_1 = 200^\circ\text{C} \quad T_2 = ?$$

A horizontal line with an upward arrow connects the two states.

$$\Delta E = \Delta U$$

$$Q = 0$$

$$\textcircled{W} = -\textcircled{\Delta U}$$

$$\Delta U = Q - W$$

Mind it, it's not specified that it is a gas or a liquid, it is just a fluid, the equation of the state for that particular fluid is also suggested. If you find equation of state it is something of Pv equals to a constant into T , right? But the constant is not equal to R in this case. So therefore it possibly is not an ideal gas but it can be represented by an equation of state for a gas and we also observed that as it seems it is Pv equals to say $C(T)$ or $C_1 T$, so therefore since it resembles the equation of state of an gas that is why u has been expressed in this case as a function of temperature only.

Now what are you required to find out here? You are first required to find out C_p and C_v for this particular gas or for this particular fluid and then you are supposed to compute some change of state for this particular fluid from some initial state to some final state, what is the initial state? The pressure of the initial state is given it is 1 MPa and the temperature of the initial state is given the final pressure P_2 is also given and what are you required to find out?

In going from this state to this state you are required to find out the work done and the energy change in this particular process it's ΔE but for this case ΔE will be equal to Δu . So therefore and since it's given that it is an adiabatic process we know for this particular process Q equals to 0 and therefore we know from first law W will be equal to ΔU or ΔE in this particular case. So therefore we find that the problem reduces to finding either W or ΔU , right?

Now there is a small thing which you need to consider ΔU equals to Q minus W from our sign convention, if you follow our sign convention then in that case your W will be equal to minus of ΔU or ΔU will be equal to minus of W , this you need to keep into consideration. So for this particular change in state the T_2 is not given, so you can compute either the ΔU or you can compute the work done if you find one, you need to find the other.

(Refer Slide Time: 13:57)

PROBLEM - 2

- The properties of a certain fluid are related as follows:
 $u = 178 + 0.718t$; $Pv = 0.267(t + 273)$
 where u is the ^{specific} molar internal energy (kJ/kg), t is in $^{\circ}\text{C}$, P is pressure (kN/m 2), v is the specific volume (m 3 /kg).
- a. For the fluid, find C_v and C_p .
- b. A stationary system consisting of 2 kg of this fluid expands in an adiabatic process according to $PV^{1.2} = \text{constant}$. The initial conditions are 1 MPa and 200 $^{\circ}\text{C}$ and the final pressure is 0.1 MPa. Find W and ΔE for the process. Why is the work transfer not equal to $\int Pdv$?

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES

In order to compute this particular change in state what is given? You have the equation of state and you have a relationship relating the specific internal energy with the temperature, you have these 2 things in mind. If you observe the equation of state you find that t is in degree plus centigrade which automatically implies that this is nothing but the absolute temperature of the system. Now we can do the first part first or even in the first part is not giving you will find that unless you find out C_p or C_v one of them, it is difficult for you to compute the second part.

(Refer Slide Time: 14:47)

$P_u = C_p T$
 $u = f(T)$
 $P_1 = 1 \text{ MPa}$
 $T_1 = 200^\circ\text{C}$
 $P_2 = 0.1 \text{ MPa}$
 $T_2 = ?$
 $U = 0.178 + 0.718t$
 $C_p \neq C_v$
 $C_p = C_v + R$
 $C_v = \left(\frac{\partial u}{\partial t}\right)_v = 0.718 \frac{\text{kJ}}{\text{kg K}}$
 $\Delta E = \Delta U$
 $Q = 0$
 $W = -\Delta U$
 $\Delta U = Q - W$

So let us first let us concentrate on the first part and then we will see how the information we have gathered from the first part helps us to find out or solve the second part of the problem, what is given here? Let me write it down it's given u equals to 178 plus $0.718t$ degree centigrade we need to find out C_v in this particular case. By definition what is the specific heat at constant volume?

We know that for most of the cases C_p will not be equal to C_v , if we knew that it was an ideal gas we could have found out C_v and we could have computed C_p as C_v plus R , in this case it is difficult to do because we do not know or rather this equation is not an ideal gas equation as is quite evident. So therefore in this particular case we cannot use this particular, in this case this equation is not going to be applicable. How to find out C_v ?

C_v by definition is $\frac{\partial u}{\partial t}$ at constant v , isn't it? So therefore if we differentiate this equation with respect to t , what do we get? We get 0.718 kilojoules per kg degree Kelvin whether it is going to be kg or moles or whether it is going to be joules or calories that all depends upon the units in which u and t has been specified.

(Refer Slide Time: 16:20)

PROBLEM – 2

- The properties of a certain fluid are related as follows:
 $u = 178 + 0.718t$; $Pv = 0.267(t+273)$
 where u is the specific internal energy (kJ/kg), t is in $^{\circ}\text{C}$, P is pressure (kN/m²), v is the specific volume (m³/kg).

- For the fluid, find C_v and C_p .
- A stationary system consisting of 2 kg of this fluid expands in an adiabatic process according to $PV^{1.2} = \text{constant}$. The initial conditions are 1 MPa and 200 $^{\circ}\text{C}$ and the final pressure is 0.1 MPa. Find W and ΔE for the process. Why is the work transfer not equal to $\int Pdv$?

IIT KHARAGPUR NPTEL ONLINE CERTIFICATION COURSES

In this particular case if you observe we find that the specific internal energy has been specified in terms of this kilo joules per kg t is in degree centigrade, so the unit of C_v is as given.

(Refer Slide Time: 16:30)

CET
I.I.T. KGP

$$Pv = C_v T \quad C_p$$

$$u = f(T) \quad C_v$$

$$P_1 = 1 \text{ MPa} \quad P_2 = 0.1 \text{ MPa}$$

$$T_1 = 200^{\circ}\text{C} \quad T_2 = ?$$

$$u = 178 + 0.718t$$

$$C_p \neq C_v \quad \boxed{C_p \neq C_v + R}$$

$$C_v = \left(\frac{\partial u}{\partial T} \right)_v = 0.718 \frac{\text{kJ}}{\text{kg K}}$$

$$C_p = \left(\frac{\partial h}{\partial T} \right)_p \quad h = u + pv$$

$$h = 178 + 0.718t + 0.267(t+273)$$

$$h = 250.891 + 0.985t$$

$$\Delta U = Q - W$$

$$Q = 0$$

$$\Delta U = -W$$

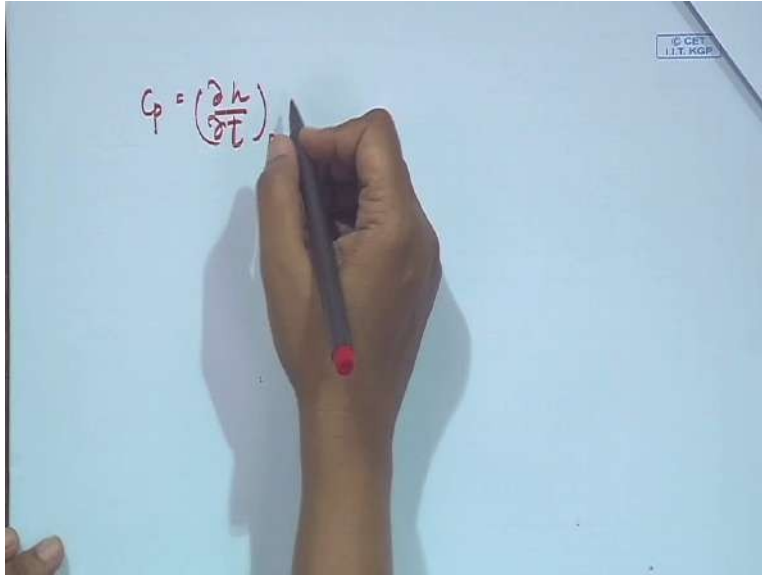

$$W = -\Delta U$$

How to find out C_p ? What is C_p by definition? $\Delta h / \Delta T$ at constant P , what is this h ? This is nothing but equals to u plus pv , right? What is, if from the problem what is u ? u is nothing but equals to 178 plus $0.718t$. What is pv equals to? This is going to be 0.267 into t plus 273 , so therefore from this equation can you not express h in terms of temperature? What is the equation?

I will just write down here in this particular equation we will find h is nothing but equals to 250.891 plus 0.985t, isn't it?

So therefore from here we can find out that h if you differentiate h with respect to t, what do you get? You get the Cp value.

(Refer Slide Time: 17:51)

A photograph showing a hand holding a black pen, writing the equation $C_p = \left(\frac{dh}{dt}\right)$ on a whiteboard. The equation is written in red ink. The hand is positioned on the right side of the frame, and the whiteboard is the background. There is a small logo in the top right corner of the whiteboard that reads "© CBT 11T.KGP".

So in this particular case what is the Cp value that you are getting? Cp which is nothing but equal to $\frac{dh}{dt}$ at constant P, please remember small t is for degree centigrade capital T is for degree Kelvin, from here we get this to be 0.985 kilo joules per kg Kelvin there is another interesting thing that I would like to mention in this particular case.

We notice that in this particular case what is Cp minus Cv equals to? Cp minus Cv if you subtract one from the other what do you get? You get this is equal to, sorry your Cv was equal to 0.718, so this is 7, this is 6, this is 2 it is 0.267, what is this 0.267?

(Refer Slide Time: 18:54)

PROBLEM – 2

- The properties of a certain fluid are related as follows:
 $u = 178 + 0.718t$; $Pv = 0.267(t+273)$
 where u is the specific internal energy (kJ/kg), t is in °C, P is pressure (kN/m²), v is the specific volume (m³/kg).

- For the fluid, find C_v and C_p .
- A stationary system consisting of 2 kg of this fluid expands in an adiabatic process according to $Pv^{1.2} = \text{constant}$. The initial conditions are 1 MPa and 200°C and the final pressure is 0.1 MPa. Find W and ΔE for the process. Why is the work transfer not equal to $\int P dv$?

Just refer to this problem you will find this is the constant $C_1 T$ which would have corresponded to R for an ideal gas equation. So therefore what does it imply?

(Refer Slide Time: 19:06)

Handwritten notes on a whiteboard:

$Pv = C_1 T$
 $u = f(T)$
 $P_1 = 1 \text{ MPa}$
 $T_1 = 200^\circ\text{C}$
 $P_2 = 0.1 \text{ MPa}$
 $T_2 = ?$

$\Delta E = \Delta U$
 $Q = 0$
 $W = -\Delta U$
 $\Delta U = Q - W$
 $h = 178 + 0.718t + 0.267(t+273)$

$C_p = C_v + R$
 $C_v = 0.718 \text{ kJ/kg K}$
 $C_p = 0.718 + 0.267 = 0.985 \text{ kJ/kg K}$

(Refer Slide Time: 19:37)

PROBLEM – 2

- The properties of a certain fluid are related as follows:
 $u = 178 + 0.718t$; $Pv = 0.267(t+273)$
 where u is the specific internal energy (kJ/kg), t is in °C, P is pressure (kN/m²), v is the specific volume (m³/kg).

- For the fluid, find C_v and C_p .
- A stationary system consisting of 2 kg of this fluid expands in an adiabatic process according to $Pv^{1.2} = \text{constant}$. The initial conditions are 1 MPa and 200°C and the final pressure is 0.1 MPa. Find W and ΔE for the process. Why is the work transfer not equal to $\int P dv$?

IIT KHARAGPUR NPTEL ONLINE CERTIFICATION COURSES

It implies that if you have a equation of Pv equals to C_1T , then in this particular case C_p minus C_v will always be equal to the constant which is C_1 , for an ideal gas this constant C_1 reduces to R , right? But here the very common tendency which I find among students is they just see you have to find out C_p , C_v . u is given, so they find out C_v and then they simply add it up with R and try to find out C_p but did not notice that it is applicable only for an ideal gas and for no other situation.

(Refer Slide Time: 20:04)

© CET
IIT KGP

$Pv = C_1T$
 $u = f_1(T)$

$P_1 = 1 \text{ MPa}$
 $T_1 = 200^\circ\text{C}$

Adiabatic
Polytropic
process
 $Pv^{1.2} = P_2v_2$

$P_2 = 0.1 \text{ MPa}$
 $T_2 = ?$

$W = -\Delta U$
 $\Delta U = Q - W$
 $h = 250.891 + 0.995t$

C_p
 C_v

$C_p - C_v = C_1$
 For an ideal gas
 $C_1 = R$

$u = 178 + 0.718t$
 $C_p \neq C_v$ $C_p \neq C_v + R$
 $C_v = \left(\frac{\partial u}{\partial t}\right)_v = 0.718 \frac{\text{kJ}}{\text{kg K}}$
 $C_p = \left(\frac{\partial h}{\partial T}\right)_P$
 $h = u + Pv$
 $= 178 + 0.718t + 0.267(t+273)$

Now let us come up to the next part of the problem, now for this part of the problem there are initial conditions given final condition is given the process is specified, what is the process? The process occurs according to this particular, this particular equation, right? And what is this equation? This equation as you know this equation is for a polytropic process, isn't it? It is already mentioned it is adiabatic, so it is an adiabatic polytropic process that we are going to deal with this, fine.

So for this process if you know you know $P_1 v_1$ to the power 1.2 should be equals to $P_2 v_2$ to the power 1.2 the initial conditions are given you need to find out the final conditions but if you wish to use this equation you will find the equation is in terms of Pv whereas initial conditions are given in terms of P and T which is quite understandable as I have already mentioned that pressure and temperature are the easily measurable and more accurately measurable variables.

So for that what do you need to do? You simply need to convert or express v in terms of T and for that you need to use this particular equation.

(Refer Slide Time: 23:07)

Handwritten calculations on a blue background:

$$C_p = \left(\frac{\partial h}{\partial T} \right)_p = 0.985 \frac{\text{kJ}}{\text{kg K}}$$

$$C_p - C_v = \frac{0.985}{0.807} - \frac{0.985}{0.718} = 0.267$$

$$P_1 v_1^{1.2} = P_2 v_2^{1.2}$$

$$P_1 \left(\frac{0.267 T_1}{P_1} \right)^{1.2} = P_2 \left(\frac{0.267 T_2}{P_2} \right)^{1.2}$$

$$T = 49.25^\circ\text{C}$$

$$\Delta U = \int m C_v dT = m C_v (T_2 - T_1) = 2 \times 0.718 (49.25 - 200) = -216.48 \text{ kJ}$$

$$W = -\Delta U = 216.48 \text{ kJ}$$

So therefore how do we go about this then? We know that Pv equals to 0.267 into capital T say, okay. I just make it first for convenience. So $P_1 0.267 T_1$ by P_1 to the power 1.2 should be equals to $P_2 0.267$ by P_2 into T_2 whole to the power 1.2, so by this equation I could actually relate the pressure temperature of state one to the pressure temperature of state two. I can solve this out

and I can find out the temperature t it comes out to be 49.25 the temperature in degree centigrade comes out to be 49.25 centigrade.

So once I know and I can always compute Δu for this particular case, what is it? It is $mC_v\Delta T$, right? Integral of this or in other words since C_v remains constant. So it is T_2 minus T_1 , m you already know it's given 2kgs, C_v you have already found out from the previous problem it is 0.718, you know T_2 by this time you know T_1 by this time, so therefore it is 49.25 minus 200 which gives you minus 216.48 kilojoules.

As a result you know W it is nothing but equals to minus of Δu which is nothing but equals to 216.48 kilojoules. Now this is one particular process of doing it, you can also do it by first computing W and then computing u that can also be done.

 $h = 250.991 + 0.995t$

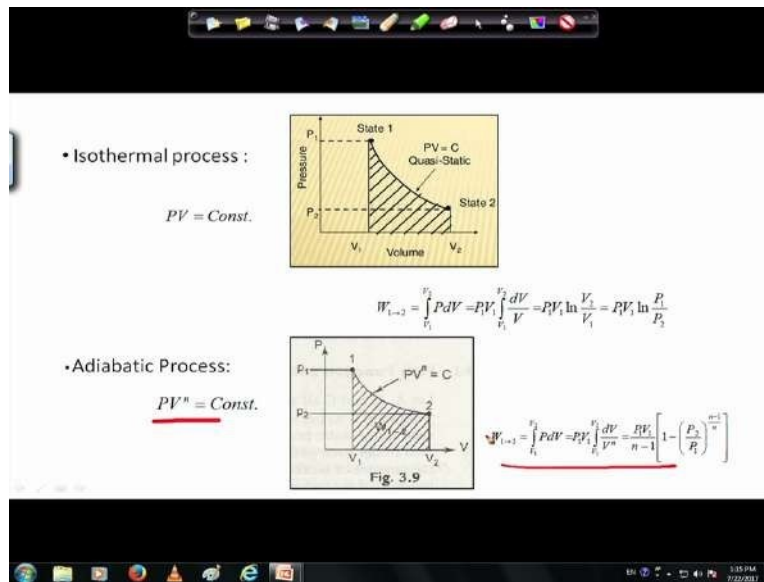

Right side: $P_2 = 0.1 \text{ MPa}$
 $T_2 = ?$
 $u = 0.178 + 0.718t$
 $C_p \neq C_v$
 $C_p = C_v + R$
 $C_v = \left(\frac{\partial u}{\partial T}\right)_v = 0.718 \frac{\text{kJ}}{\text{kg K}}$
 $C_p = \left(\frac{\partial h}{\partial T}\right)_p$
 $h = u + Pv$
 $= 178 + 0.718t + 0.267t$

(Refer Slide Time: 23:30)

You know that the process is an adiabatic polytropic process, now if you recall that when we were discussing these particular things I had already discussed the PvT work in various quasi-static processes. I have discussed PvT Work for an isobaric, isochoric, isothermal and then adiabatic process, in fact this is specifically not an adiabatic process this is a polytropic process it becomes adiabatic when this n becomes equal to gamma, right?

(Refer Slide Time: 24:12)

So can we not use this particular equation here in order to find out, if we can use this particular equation here, this is the equation so can we not use this particular equation in order to find out W. We can do it, right? But again in order to use this equation you know P1, you do not know V1.

(Refer Slide Time: 24:39)

$C_p = \left(\frac{\partial h}{\partial T} \right)_p = 0.985 \frac{\text{kJ}}{\text{kg K}}$
 $C_p - C_v = \frac{0.985}{0.807} - \frac{0.985}{0.718} = 0.267$
 $P_1 \left(\frac{0.267 T_1}{P_1} \right)^{1.2} = P_2 \left(\frac{0.267}{P_2} T_2 \right)^{1.2}$
 $t = 49.25^\circ \text{C}$
 $\Delta U = \int m C_v dT = m C_v (T_2 - T_1) = 2 \times 0.718 (49.25 - 200)$
 $= -216.48 \text{ kJ}$
 $W = -\Delta U = 216.48 \text{ kJ}$

So you again have to express V1 in terms of temperature in terms of temperature, where V1 in this particular case I have already written down your V1 is nothing but this part, isn't it? So

therefore you can substitute V_1 , n is nothing but 1.2, P_2 and P_1 both are known to you so therefore you can find out W in this case and equate this W with Δu .

(Refer Slide Time: 25:01)

Handwritten calculations on a blue background:

$$C_p = \left(\frac{\partial h}{\partial T} \right)_p = 0.985 \frac{\text{kJ}}{\text{kg K}}$$

$$C_p - C_v = \begin{array}{r} 0.985 \\ -0.718 \\ \hline 0.267 \end{array}$$

$$P_1 \left(\frac{0.267 T_1}{P_1} \right)^{1.2} = P_2 \left(\frac{0.267 T_2}{P_2} \right)^{1.2}$$

$$T = 49.25^\circ\text{C}$$

$$\Delta U = \int m C_v dT = m C_v (T_2 - T_1) = 2 \times 0.718 (49.25 - 200) = -216.48 \text{ kJ}$$

$$W = -\Delta U = 216.48 \text{ kJ}$$

I give it as an exercise to find out W independently from this equation and compare the value with the W which you have obtained by equating this with Δu . Just to show that once the path is specified no matter how you do the computation? The work done will be the same for both the cases.

(Refer Slide Time: 25:25)

The screenshot shows a presentation slide titled "PROBLEM - 3". The slide contains the following text:

- Calculate the heat interactions and entropy change during reversible isothermal expansion of an ideal gas. Also calculate the heat interactions and entropy change when the same gas undergoes the same change in state by
 - a. Isobaric expansion followed by isochoric cooling.
 - b. Adiabatic expansion followed by isochoric heating.

Assume all processes to be reversible.

Handwritten notes in red ink on the right side of the slide include:

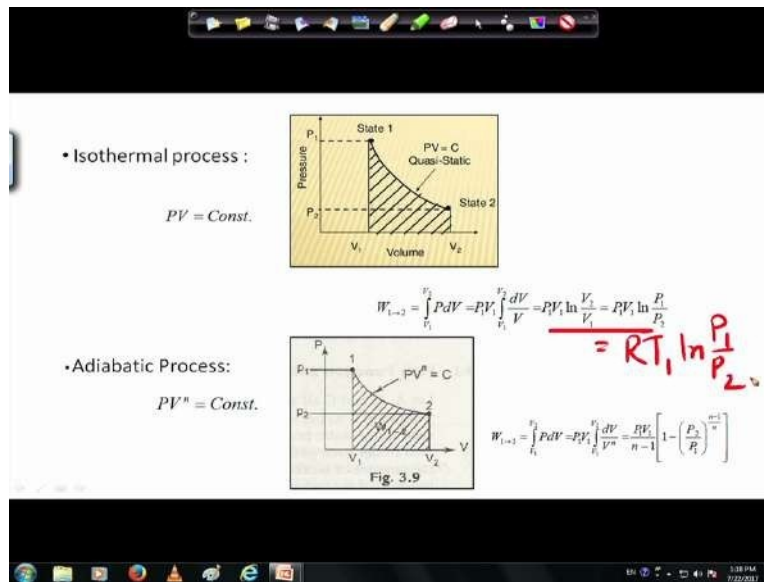

$$P_1 V_1 T = P_2 V_2 T$$
$$dU = 0$$
$$dQ = dW$$

The slide also features logos for IIT KHARAGPUR and NPTEL ONLINE CERTIFICATION COURSES at the bottom.

Now we move on to the third problem, let us see what the third problem is? This is also another problem in order where we perform some particular change of state and from that particular change of state we try to find out the heat interactions and with that one additional thing also we would like to find out in this particular case the entropy change, right? What is the process that we have devised? This system is an ideal gas and for an ideal gas what is the process? It is a reversible isothermal expansion.

So if it is a reversible isothermal expansion, what does it imply? It implies that the change of state it will be from $P_1 V_1$ temp T to say $P_2 V_2$ T , isn't it? And for this particular change of state since it is an ideal gas we know that since T remains constant for an isothermal process du is equal to 0. So therefore for this process we know dQ is going to be equal to dW . So therefore to find heat interactions we can find out the work done, from the work done can find out the heat interactions.

(Refer Slide Time: 26:57)

For an isothermal process again if we go back to the equations which I had shown for an isothermal process Pv equals to constant and this is the expression for the work done, isn't it? So therefore in this particular case $P_1 V_1$ is nothing but equals to RT_1 . So therefore this can also be written down as $RT_1 \ln P_1$ by P_2 , agreed? So therefore we can find out the work done and this will be equal to the heat interactions under this particular process.

(Refer Slide Time: 27:37)

PROBLEM – 3

- Calculate the heat interactions and entropy change during reversible isothermal expansion of an ideal gas. Also calculate the heat interactions and entropy change when the same gas undergoes the same change in state by
 - Isobaric expansion followed by isochoric cooling.
 - Adiabatic expansion followed by isochoric heating.
 Assume all processes to be reversible.

IIT KHARAGPUR
 NPTEL ONLINE CERTIFICATION COURSES

So accordingly in order to find out the heat interactions for reversible isothermal expansion ideal gas you have already got the expressions we had already derived the expressions.

(Refer Slide Time: 27:51)

Handwritten equations on a blue background:

$$dW_{rev} = nRT_1 \ln \frac{P_1}{P_2} = nRT_1 \ln \frac{V_2}{V_1}$$

$$dU = 0$$

$$dQ_{rev} = dW_{rev} = nRT_1 \ln \frac{V_2}{V_1}$$

$$\int_{S_1}^{S_2} dS = \frac{dQ_{rev}}{T} \int_1^2 \frac{nRT_1}{T_1 V} dV = nR \ln \frac{V_2}{V_1} = \Delta S$$

So for this particular case your dW reversible was equal to as I have shown you it was $nRT_1 \ln P_1$ by P_2 or else you can also write it down as $nRT_1 \ln V_2$ by V_1 , right? We know that ideal gas dU equals to 0. So therefore dQ reversible will be equal to dW reversible will be equal to $nRT_1 \ln V_2$ by V_1 , right?

But here we are required to find out the entropy change as well, if you recollect what is dS ? It is nothing but equal to dQ reversible by T in this particular case T remains constant. So therefore in this case if you substitute it, we will find out that this is nRT_1 by $T_1 V$ dv which is nothing but equal to, if you integrate this particular equation say from state one to state 2 say S_1 to S_2 or in other words just from state 1 to state 2. We need to integrate this also from state 1 to state 2, so therefore this gives us $nR \ln V_2$ by V_1 this is equals to ΔS for this particular process, right?

(Refer Slide Time: 29:39)

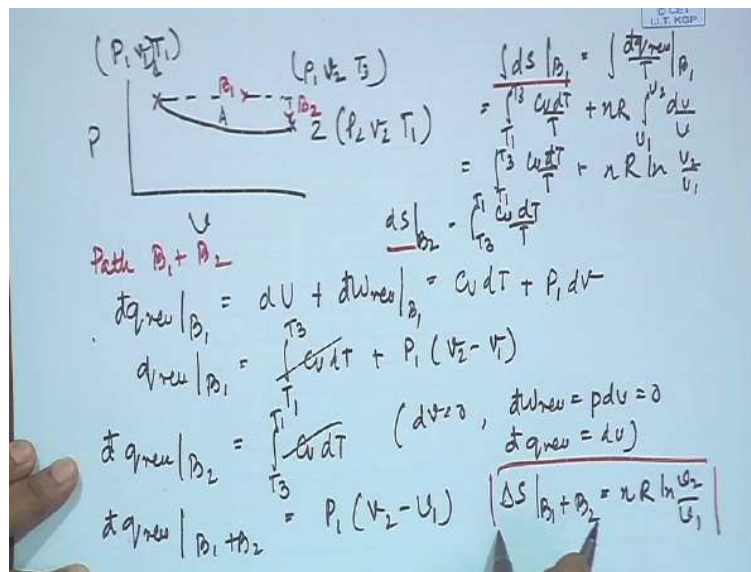

PROBLEM – 3

- Calculate the heat interactions and entropy change during reversible isothermal expansion of an ideal gas. Also calculate the heat interactions and entropy change when the same gas undergoes the same change in state by
 - Isobaric expansion followed by isochoric cooling.
 - Adiabatic expansion followed by isochoric heating.
 Assume all processes to be reversible.

 IIT KHARAGPUR
  NPTEL ONLINE CERTIFICATION COURSES

But this was pretty simple but the problem does not end here we are required to find out the heat interactions then the entropy changes for 2 other processes which provided the initial and final states are the same. What are the 2 other processes? The 2 other processes are isobaric expansion followed by isochoric cooling, adiabatic expansion followed by isochoric heating and all the processes have to be reversible.

(Refer Slide Time: 30:02)

(Refer Slide Time: 30:08)

Handwritten equations on a whiteboard:

$$dW_{rev} = nRT_1 \ln \frac{P_1}{P_2} = nRT_1 \ln \frac{V_2}{V_1}$$

$$dU = 0$$

$$dQ_{rev} = dW_{rev} = nRT_1 \ln \frac{V_2}{V_1}$$

$$\int_{S_1}^{S_2} dS = \int_{T_1}^{T_2} \frac{dQ_{rev}}{T} = nR \ln \frac{V_2}{V_1} = \Delta S$$

So if we just plot it, simply for ease of your visualization this was state 1, this was state 2 this was the process which we performed this was P_1V_1 , this was P_2V_2 say T_1 here also it was T , this process we have already performed and we have found out the heat interactions and the entropy changes in for this particular case this is say process A, what is process B? Isobaric expansion so that means pressure P is constant

This is isobaric expansion followed by isochoric cooling, right? So the process B is, you proceed in this way and you proceed in this way. Now for this particular process it comprises of 2 processes say B1 and B2, for this particular B1 plus B2 we can very well write down dq reversible along B1, what is this? This is du plus dW reversible along B1, what is dU in this particular case? This is an isobaric, this is dU is going to be $C_v dT$ plus dQ reversible under this case. So therefore this is going to be $P_1 dv$, isn't it?

So therefore q reversible along B1 this is going to be your integral and here if I specify the states it is going to be P_1 , all of these are small they are molar $P_1 v_2$ and say T_3 . So therefore this has to be integrated from T_1 to T_3 $C_v dT$ plus $P_1 (V_2 - V_1)$, agreed? So this is a q reversible for this particular path.

What is dq reversible for B2? In this particular case we have integral T_3 to T_1 $C_v dT$, since this is an isochoric process so naturally dv equals to 0, so naturally dW reversible which is equals to $P dv$ will be equals to 0, right? So therefore in this particular case what do we have? We have dq

reversible equals to dU . So therefore automatically we find that when such a situation arises the heat interaction behaves or can be evaluated from this as a state function as it is.

So now what is $dq_{\text{reversible}}$ for the entire process B1 plus B2? You add this and this with this, when you add you will find that in this case the integration was performed from T1 to T3, in this case it is performed from T3 to T1. So therefore since we have just the initial and final states are the same we are just reversing it. So therefore these 2 cancel out and we find this is equals to P_1 into V_2 minus V_1 , I am sorry I am repeatedly writing it s capital. So therefore this is $dq_{\text{reversible}}$.

What is the entropy change now let us see? Entropy change ds along B1 it is going to be integral of this integral this is $dq_{\text{reversible}}$ by T along B1, right? So therefore $dq_{\text{reversible}}$ T along B1, I need to integrate this I need to integrate this, so therefore what does it amount to T1 to T3 $C_v dT$ by T plus nR integral V_1 to V_2 dv by v , agreed which is nothing but equals to T1 to T3 $C_v dT$ by T plus $nR \ln V_2$ by V_1 .

What is ds along B2 tell me? This is nothing but T3 to T1 $C_v dT$ by T , right? Now add this particular (ds) and this particular (ds) to get the Δs along path B1 plus B2, what is this? This is equals to $nR \ln V_2$ by V_1 .

(Refer Slide Time: 34:51)

$dU = 0$
 $dQ_{rev} = dW_{rev} = nRT_1 \ln \frac{V_2}{V_1}$
 $\int_{S_1}^{S_2} dS = \frac{dQ_{rev}}{T} = \int_1^2 \frac{nRT_1}{T_1} \ln \frac{V_2}{V_1} = nR \ln \frac{V_2}{V_1} = \Delta S$
 $\Delta S |_{B_1+B_2} = nR \ln \frac{V_2}{V_1}$

Compared this with the ΔS that you had obtained for an isothermal process, what do you find? You find that the ΔS for both the cases are the same but we find that the dq for this process and the dq for this process they are not the same.

(Refer Slide Time: 35:08)

(P_1, V_1, T_1)
 (P_2, V_2, T_2)
 (P_3, V_3, T_3)
 $\Delta S |_{B_1} = \int_{T_1}^{T_2} \frac{C_v dT}{T} + nR \int_{V_1}^{V_2} \frac{dV}{V}$
 $= \int_{T_1}^{T_2} \frac{C_v dT}{T} + nR \ln \frac{V_2}{V_1}$
 $\Delta S |_{B_2} = \int_{T_2}^{T_3} \frac{C_v dT}{T}$
 $= C_v \ln T + P_1 dV$
 $P_1 (V_2 - V_1)$
 $(dV=0, dW_{rev} = PdV=0)$
 $dQ_{rev} = dU$
 $\Delta S |_{B_1+B_2} = nR \ln \frac{V_2}{V_1}$

Again you can repeat it for the next process which is given, the next process is nothing but your adiabatic expansion, say for the next process what is it? This is basically the adiabatic expansion followed by the isochoric heating. So therefore here we start from $P_1V_1T_1$ along a process say

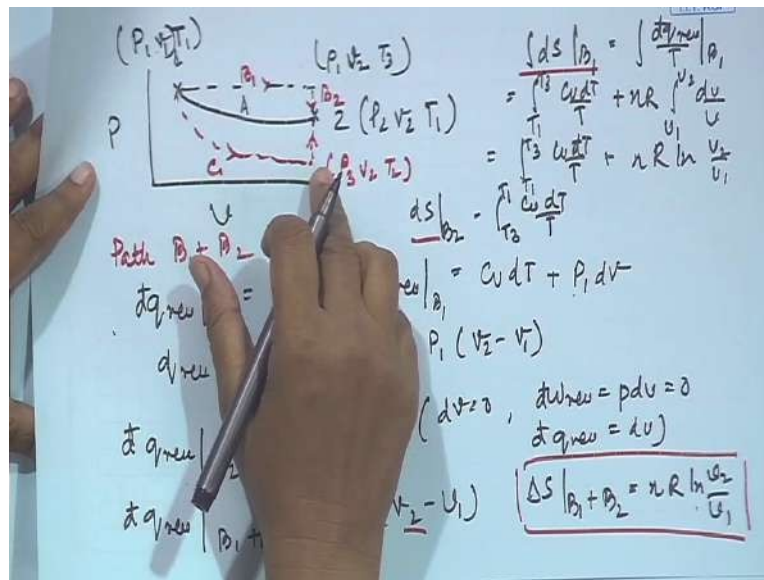

C1 to arrive to P3V2T2 and then from there we come to this process. For this process also, we can proceed I believe you could have done it on your own.

(Refer Slide Time: 35:40)

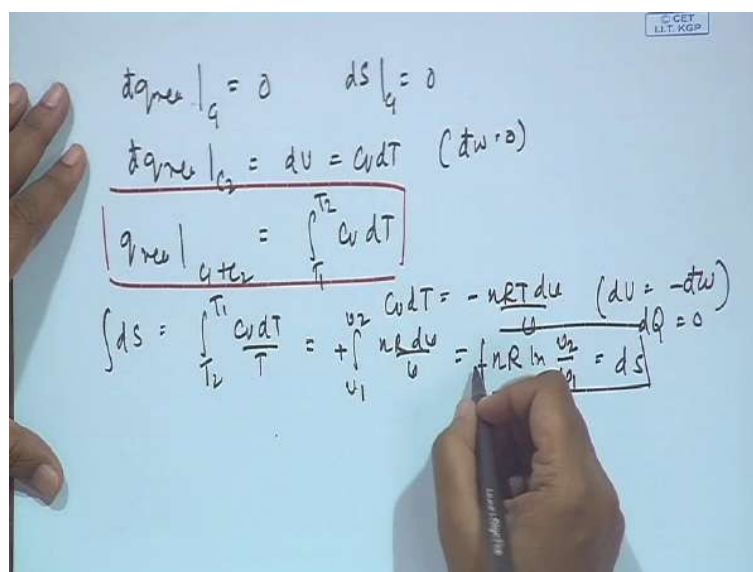

But suppose we work it out say dq reversible along C1 that is equal to 0 because it is adiabatic, so therefore dS along this process it is going to be 0, dQ reversible along C2 is nothing but du which is equal to $C_v dT$ again since for an isochoric process dW equals to 0 I have already told you. So therefore what is q reversible along C1 plus C2? It is just $C_v dT$, right? What is dS for this process let us see? This is going to be integral T_2 to T_1 $C_v dT$ by T , right?

(Refer Slide Time: 36:22)

And we can also for this particular path C1, say for this particular path C1 we can also write that C_{vdT} equals to minus $nRt dv$ by v , why? Because du equals to minus w since dq equals to 0, right? So therefore instead of the C_{vdT} by T , can we not substitute it with minus $V1$ BY $V2$ $nR dv$ by v , which gives us minus $nR \ln v2$ by, in this particular case there was a minus, very sorry so it becomes a plus so therefore this is ds in this particular case, right?

(Refer Slide Time: 37:20)

(Refer Slide Time: 37:28)

$$\begin{aligned}
 dq_{rev}|_{P_1} &= dU + dw_{rev}|_{P_1} = C_v dT + P_1 dv \\
 dq_{rev}|_{P_1} &= \int_{T_3}^{T_1} C_v dT + P_1 (V_2 - V_1) \\
 dq_{rev}|_{P_2} &= \int_{T_3}^{T_1} C_v dT \quad (dv=0, \quad dw_{rev} = pdv=0, \quad dq_{rev} = dU) \\
 dq_{rev}|_{P_1+P_2} &= P_1 (V_2 - V_1) \quad \boxed{\Delta S|_{P_1+P_2} = nR \ln \frac{V_2}{V_1}} \\
 dS &= \int \frac{C_v dT}{T} + \int \frac{nR du}{u} = \int nR \ln \frac{V_2}{V_1} = dS \\
 dw_{rev} &= nRT_1 \ln \frac{P_1}{P_2} = nRT_1 \ln \frac{V_2}{V_1} \\
 dU &= 0 \\
 dq_{rev} &= dw_{rev} = nRT_1 \ln \frac{V_2}{V_1}
 \end{aligned}$$

Again if we compare the q reversible and the ds 's what do we find? I can just superimpose it on this and if you observe all the 3 what do you find? For this particular path this $nR \ln v_2$ by v_1 , for this path it is $nR \ln v_2$ by v_1 , in this case also it is the same which automatically implies Δs is a property of the system and no matter what path we follow, provided the paths are reversible we know that Δs it is going to be the same provided the paths are reversible.

(Refer Slide Time: 38:25)

$$\begin{aligned}
 dq_{rev}|_{P_2} &= \int_{T_3}^{T_1} C_v dT \quad (dv=0, \quad dw_{rev} = pdv=0, \quad dq_{rev} = dU) \\
 dq_{rev}|_{P_1+P_2} &= P_1 (V_2 - V_1) \quad \boxed{\Delta S|_{P_1+P_2} = nR \ln \frac{V_2}{V_1}} \\
 q_{rev}|_{T_1} &= \int_{T_1}^{T_2} C_v dT \\
 C_v dT &= -nR \frac{du}{u} \quad (dT = -nR \frac{du}{u}) \\
 \Delta S &= \text{property of system} \\
 dw_{rev} &= nRT_1 \ln \frac{P_1}{P_2} = nRT_1 \ln \frac{V_2}{V_1} \\
 dU &= 0 \\
 dq_{rev} &= dw_{rev} = nRT_1 \ln \frac{V_2}{V_1}
 \end{aligned}$$

On the contrary we find Δs from this particular formula that Δs equals to d , we find it from this particular formula but here even if you are finding it from a path function it is a property but

the heat computed for all the 3 cases this is for case 1, this is for case 2 and this is for case 3 this is for case 3 we find that the heat interactions along the three-paths they are different. Although the entropy change is the same for all the 3, thank you very much and I look forward to further interactions while we proceed in this particular course, thank you.
