Boundary Layers (Cont.)

(Refer Slide Time: 00:17)

In continuation with what we have done in the previous class, we were looking at how to analyze the growth of a boundary layer on a flat plate in laminar flow. The objective of that exercise was to obtain δ , the thickness of the boundary layer as a function of actual distance that is the distance along the length of the plate. And we have also seen that inside the boundary layer the flow is two-dimensional. Outside of the boundary layer, the flow is inviscid in nature such that Euler's equation, Bernoulli's equation is applicable. However inside the boundary layer, the complete Navier–Stokes equation has to be solved in order to obtain the profile of the thickness of the boundary layer as a function of x where x denotes the actual distance.

We, from our basic understanding of the physics of the process, we have done some analysis based on which is going to be a significant term in Navier–Stokes equation and which is not. First of all we have assumed that it is a zero pressure gradient flow and since the plate is horizontal there would be no effect of gravity. So the, and it's a two dimensional flow where the velocity v_x , velocity components v_x and v_y would be functions of both x and y . The plate is wide in the z direction therefore the z dependence of velocity does not appear in the, in our analysis of Navier–Stokes equation. So we have four terms in the Navier–Stokes equation. The first two on the left hand side as we have seen before, these two terms,

(Refer Slide Time: 02:04)

BOUNDARY LAYER APPROXIMATIONS ←

LAMINAR FLOW ON A FLAT PLATE

x
COMP.

$\delta(x)$ SMALL

$$v_x \frac{\partial v_x}{\partial x} + v_y \frac{\partial v_x}{\partial y} = \nu \left[\frac{\partial^2 v_x}{\partial x^2} + \frac{\partial^2 v_x}{\partial y^2} \right]$$

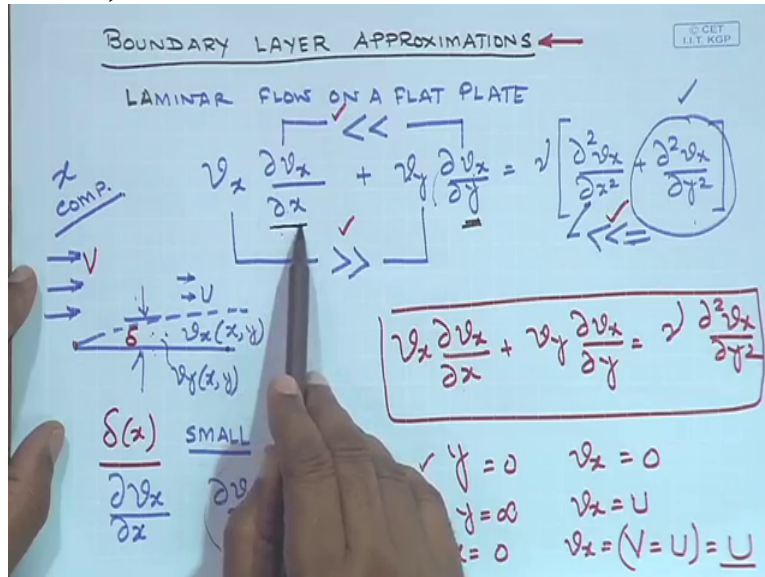

←<< >>←

$$v_x \frac{\partial v_x}{\partial x} + v_y \frac{\partial v_x}{\partial y} = \nu \frac{\partial^2 v_x}{\partial y^2}$$

$y = 0 \quad v_x = 0$
 $y = \infty \quad v_x = U$
 $x = 0 \quad v_x = (V = U) = \underline{U}$

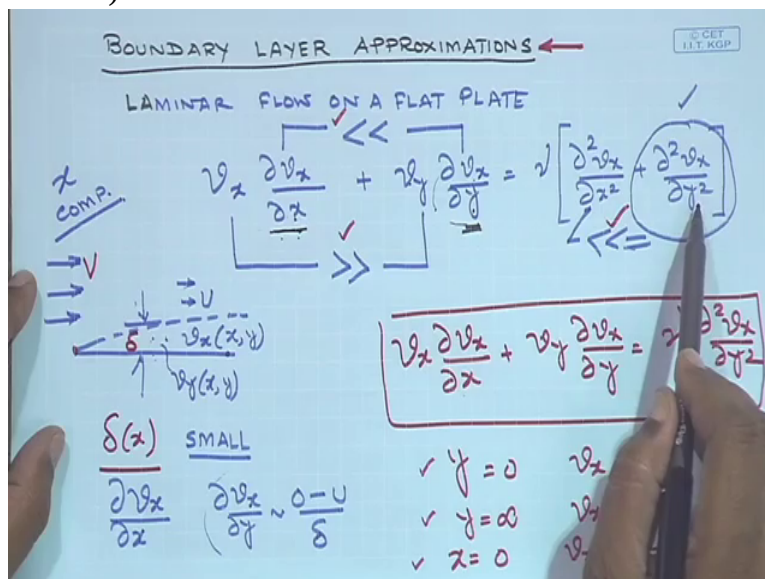

essentially they refer to the convective momentum and this is the conductive or molecular transport of momentum. And using the boundary layer approximations what we have seen is that v_x is relatively large compared to v_y because the principal motion is in the x direction. However since the thickness of boundary layer which is denoted by δ , the dimension is denoted by y , since the gradient of the variation in velocity with respect to y is large in comparison to the gradient of velocity with respect to x , none of these two terms can be neglected, can be equated to zero based on simple heuristical analysis. However if we come to the right hand side, this denotes the molecular transport of momentum in the y direction and this is molecular transport of momentum in the x direction. Since the gradient of v_x with respect to y is large, it is expected that the transport of momentum, molecular momentum in the y direction would be much more than the transport of molecular momentum in the x direction since the gradient of velocity in the x direction is small.

(Refer Slide Time: 03:28)

So based on our idea about the gradient of the x component of velocity in the y direction and in the x direction, it is safe to say that the gradient

(Refer Slide Time: 03:40)

of the molecular transport of momentum in the y direction would be much more than the molecular transport of momentum in the x direction which leads us to the governing equation and we understood that there would be no slip at y equals zero and at the edge of boundary layer or beyond the boundary layer when y mathematically speaking when y tends to infinity, the velocity would simply be equal to the freestream velocity, that is the velocity outside of the boundary layer and at the x equals to zero, v x, that is actual component of velocity in the x direction would simply be equal to u where u is the approach velocity. And we also

understand that for a flat plate, v , the approach velocity would be equal to u , the freestream velocity so therefore we can simply write $v \times$ equals u . In the next step we have

(Refer Slide Time: 04:36)

proposed

(Refer Slide Time: 04:37)

BLASIUS

$$\frac{v_x}{U} = f(\eta) \quad \eta \sim \frac{y}{\delta}$$

$$v_x \frac{\partial v_x}{\partial x} + v_y \frac{\partial v_x}{\partial y} = \nu \frac{\partial^2 v_x}{\partial y^2} \quad (2)$$

$$\frac{\partial v_x}{\partial x} + \frac{\partial v_y}{\partial y} = 0 \quad (1)$$

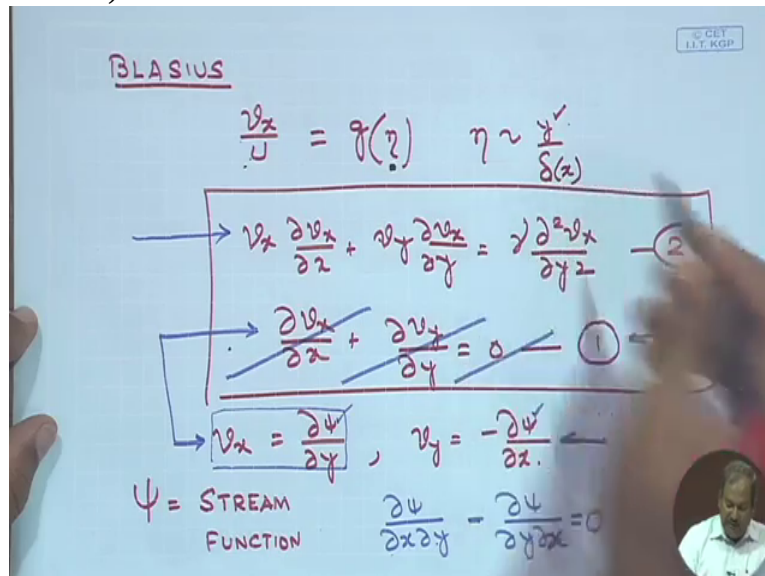

$$v_x = \frac{\partial \psi}{\partial y}, \quad v_y = -\frac{\partial \psi}{\partial x}$$

$\psi =$ STREAM FUNCTION

$$\frac{\partial \psi}{\partial x \partial y} - \frac{\partial \psi}{\partial y \partial x} = 0 \quad \psi \text{ EXACT DIFFERENTIAL}$$

the solution is by Blasius where he reasoned that the dimensionless velocity profile when plotted against the dimensionless distance from the solid wall would be similar for all cases. And this η which is the dimensionless distance from the solid wall is expressed as y by δ where δ is a local thickness of the, of the boundary layer. However we understand here that this δ is a

(Refer Slide Time: 05:11)

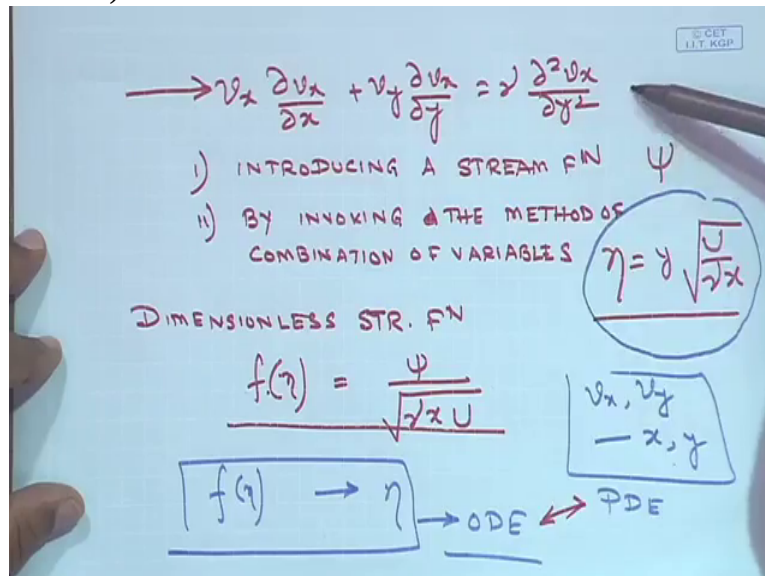

function of x as we progress in the x direction, the delta keeps on increasing. So therefore his reasoning, Blasius reasoning is that, which is supported by experimental data, that dimensionless velocity profile would be similar when plotted against the dimensionless distance from the solid wall. So with this, then we have two equations to deal with. The first one is equation of continuity and the second is equation of motion. If we introduce a stream function, then because of the properties of the stream function the first equation, the equation of continuity gets automatically satisfied and we are left only with the equation of motion. This

(Refer Slide Time: 05:57)

equation of motion

(Refer Slide Time: 05:58)

and using the method of combination of variables which we have discussed in the previous class, we are hoping that this p d e can be transformed to an o d e and that's essentially the method of combination of variables and we would see whether it would work here in this specific case or not. And since we are expressing everything in dimensionless form, so instead of a stream function, we are introducing a dimensionless stream function denoted by f and we understand that this f is a function of η , the dimensionless distance from the solid wall and this is how the dimensionless, the dimensionless stream function is expressed. So we do not deal with v_x, v_y any more, we rather deal with ψ which is a stream function since ψ we know what would be the expression for v_x if we know ψ and since it is dimensionless equation we also do substitute ψ with a dimensionless stream function.

So therefore $f(\eta)$ is a function of η and we are, we are hoping that this p d e can be transformed to an o d e when instead of $v_x \frac{\partial v_x}{\partial x} + v_y \frac{\partial v_x}{\partial y} = \nu \frac{\partial^2 v_x}{\partial y^2}$ and so on. We introduce the dimensionless stream function and instead of x and y as the independent variable we will bring η as an independent variable. So if we are correct, then our final equation would contain f and η . So if it contains f and η and if you understand that f is a function only of η then the governing equation between f and η will simply be an o d e. So this is

(Refer Slide Time: 07:47)

$$\rightarrow v_x \frac{\partial v_x}{\partial x} + v_y \frac{\partial v_x}{\partial y} = \nu \frac{\partial^2 v_x}{\partial y^2}$$

i) INTRODUCING A STREAM FN ψ .

ii) BY INVOKING THE METHOD OF COMBINATION OF VARIABLES

$$\eta = y \sqrt{\frac{U}{2x}}$$

DIMENSIONLESS STR. FN

$$f(\eta) = \frac{\psi}{\sqrt{2x}U}$$

$$f(\eta) \rightarrow \eta \rightarrow \text{ODE} \leftrightarrow \text{PDE}$$

$$\begin{matrix} \psi_x, \psi_y \\ -x, y \end{matrix}$$

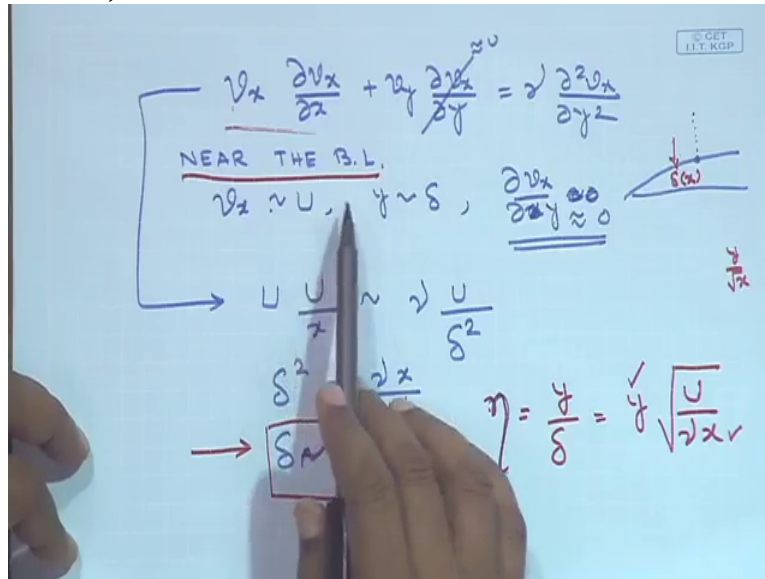

what we have, we have

(Refer Slide Time: 07:49)

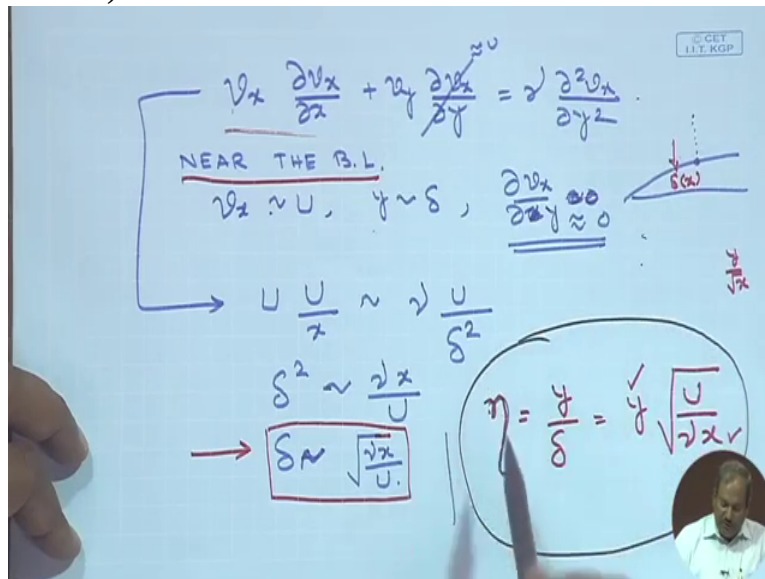

done in the previous class and based

(Refer Slide Time: 07:53)

on an approximate solution of the equation near the edge of the boundary layer where we have seen what would be the orders of magnitude of these various terms, we also have defined that the dimensionless distance

(Refer Slide Time: 08:11)

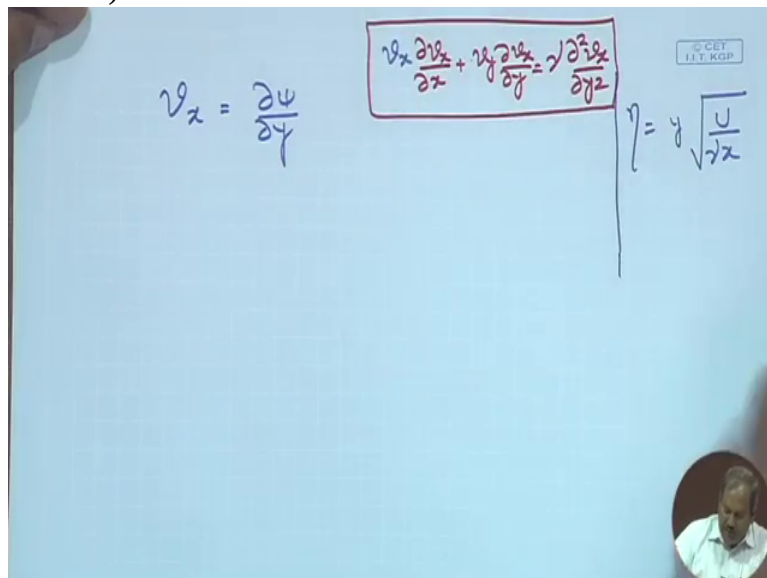

or rather the combination variable which contains both y and x should be of the form where eta equals y root u by nu x, this is the kinematic viscosity. So with this and with our definition of eta we would see whether this equation can now be transformed to an ordinary differential equation. So we

(Refer Slide Time: 08:33)

will start from that point and what we will first do is using the definition of v_x which is $\frac{\partial \chi}{\partial y}$ and I would write here how we have defined η , this is how we have defined η . And I would show you just one example and the governing equation is $v_x \frac{\partial v_x}{\partial x} + v_y \frac{\partial v_x}{\partial y} = \nu \frac{\partial^2 v_x}{\partial y^2}$. So this is the governing equation. We need to substitute

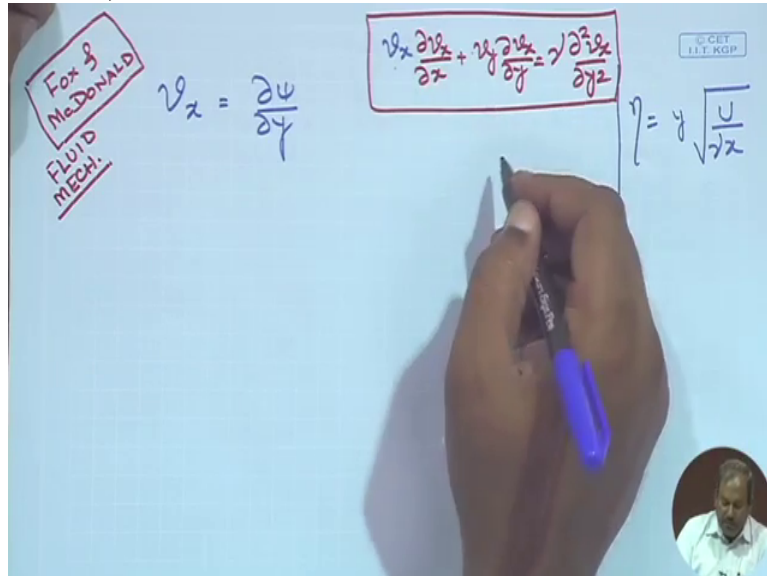

(Refer Slide Time: 09:21)

each of these terms in terms of χ or in other, in dimensionless form in terms of η . So I will just show you one, two examples of how to get the expression for v_x and v_y and the expressions for $\frac{\partial v_x}{\partial x}$ and $\frac{\partial v_x}{\partial y}$ and $\frac{\partial^2 v_x}{\partial y^2}$ are given in the textbook and for this part, I am following the book of Fox and McDonald. So if you see

the book of Fox and McDonald, Fluid Mechanics which is one of the textbooks for this course, the complete derivation

(Refer Slide Time: 10:08)

with all its particulars would be,

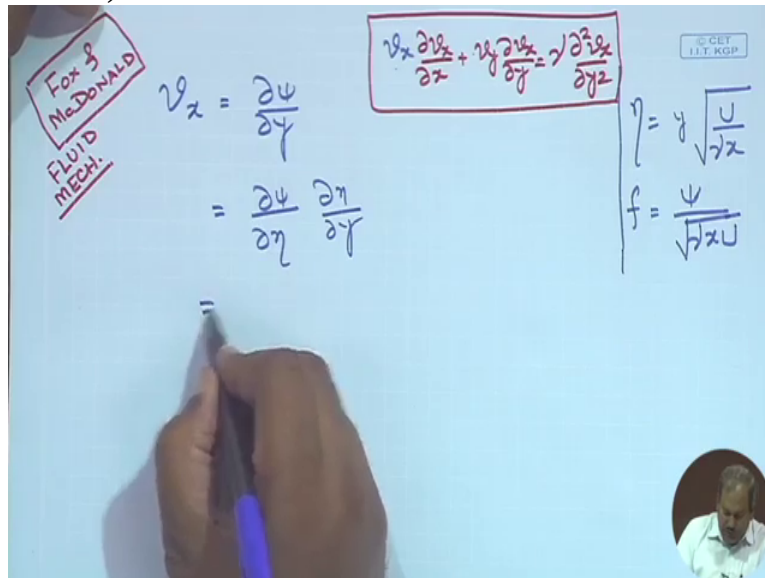

(Refer Slide Time: 10:11)

would be clear to all of you So we are trying to right now find out what is going to be the expressions for v_x , v_y and all other terms in the equation of motion in terms of χ , the dimensionless dependent variable and η , the dimensionless independent variable. The expression of η we have already obtained based on the order of magnitude analysis. So I am going to show you how to get the expression for v_x and v_y , the other terms of the equation of motion can be seen from the textbook Fox and McDonald. So let's see how we do v_x in

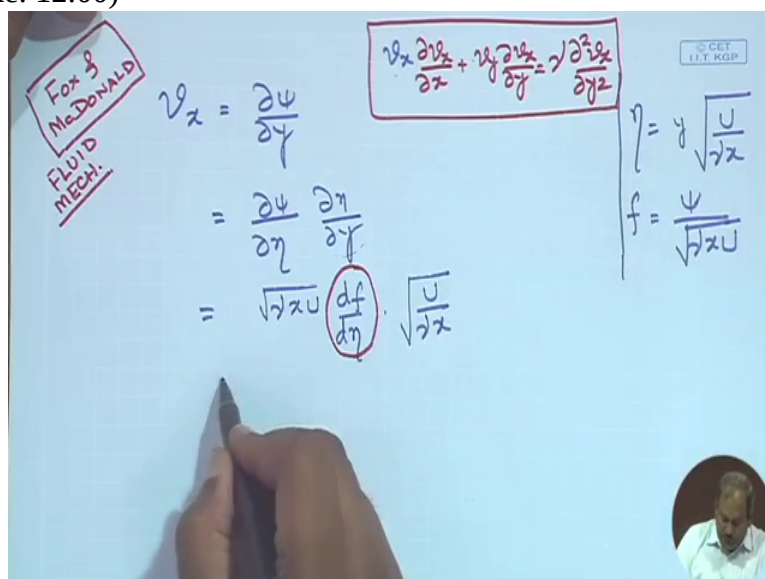

this case. So from definition, we can simply write this and if we introduce the f is defined as χ by root over $\nu x u$. So if we do this,

(Refer Slide Time: 11:13)

$\frac{\partial \chi}{\partial y}$, if we transform that χ to f it would be simply be equals $\nu x u$ times $d f$ by $d \eta$. See that since f is a function only of η , the combination variable, I am getting rid of the partial sign and I am simply getting the ordinary differential equation, ordinary differential form in this. So it is $d f$ by $d \eta$ and not $\frac{\partial f}{\partial \eta}$ and if I find out what is $\frac{\partial \eta}{\partial y}$ from over here, I would simply get as u by νx . So this directly follows from our definition of η . So therefore

(Refer Slide Time: 12:00)

this expression is u times $d f$ $d \eta$ so my v_x therefore equals u times $d f$ $d \eta$ this can subsequently be substituted in here. Similarly when we

(Refer Slide Time: 12:19)

$v_x = \frac{\partial \psi}{\partial y}$
 $= \frac{\partial \psi}{\partial \eta} \frac{\partial \eta}{\partial y}$
 $= \sqrt{\nu x U} \left(\frac{df}{d\eta} \right) \cdot \frac{1}{\sqrt{\nu x}}$
 $= U \frac{df}{d\eta}$

$v_x = U \frac{df}{d\eta}$

$\eta = y \sqrt{\frac{U}{\nu x}}$
 $\psi = U \sqrt{\nu x} f$

start with v_y which is by definition of stream function $\frac{\partial \psi}{\partial x}$, I can write it as minus $\frac{\partial \psi}{\partial x}$ instead of ψ I am going to write here as $\nu x u$ which can then

(Refer Slide Time: 12:42)

$v_y = -\frac{\partial \psi}{\partial x} = -\frac{\partial}{\partial x} [U \sqrt{\nu x} f]$

be expanded as, so this is just an expansion,

(Refer Slide Time: 12:59)

$$v_x = \frac{\partial \psi}{\partial y}$$
$$= \frac{\partial \psi}{\partial \eta} \frac{\partial \eta}{\partial y}$$
$$= \sqrt{\xi U} \left(\frac{df}{d\eta} \right) \cdot \sqrt{\frac{U}{\xi}}$$
$$= U \frac{df}{d\eta}$$
$$v_x = U \frac{df}{d\eta}$$
$$v_y = -\frac{\partial \psi}{\partial x} = -\frac{\partial}{\partial x} [f \cdot \sqrt{\xi U}]$$
$$= - \left[\sqrt{\xi U} \cdot \frac{\partial f}{\partial x} + \frac{1}{2} \sqrt{\frac{U}{\xi}} f \right]$$

Boxed equations:
 $v_x \frac{\partial v_x}{\partial x} + v_y \frac{\partial v_x}{\partial y} = \nu \frac{\partial^2 v_x}{\partial y^2}$
 $\eta = y \sqrt{\frac{U}{\nu x}}$
 $f = \frac{\psi}{\sqrt{\nu x U}}$

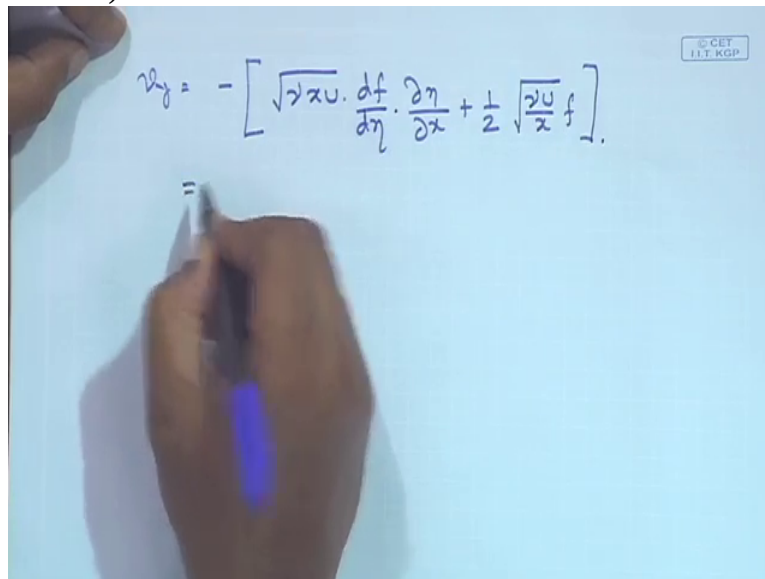

and when we continue with the derivation

(Refer Slide Time: 13:04)

of this, what we would get u i from the previous page, it is simply just a substitution

(Refer Slide Time: 13:29)

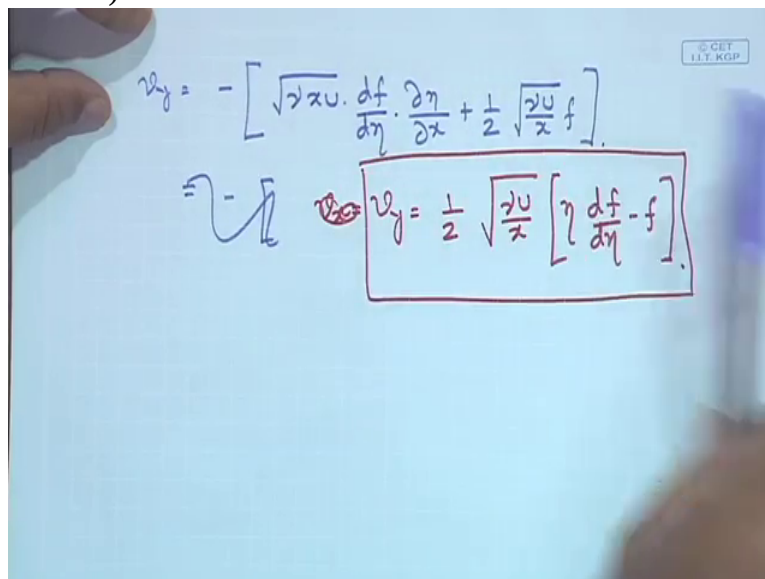

A hand is writing the following equation on a whiteboard:

$$v_y = - \left[\sqrt{\lambda x u} \cdot \frac{df}{d\eta} \cdot \frac{\partial \eta}{\partial x} + \frac{1}{2} \sqrt{\frac{\lambda u}{x}} f \right]$$

of the independent variables, so instead of $\frac{\partial f}{\partial x}$ I simply write $\frac{df}{d\eta}$ since f is a function only of η . I will simply write the final steps since it's given in a nice form in the equation, in the textbook, so this is the expression for v_y and from

(Refer Slide Time: 14:12)

A hand is writing the following equation on a whiteboard, with the previous equation crossed out:

$$v_y = \frac{1}{2} \sqrt{\frac{\lambda u}{x}} \left[\eta \frac{df}{d\eta} - f \right]$$

previous slide we have seen v_x is equal to u times $\frac{df}{d\eta}$. The expressions for and the governing

(Refer Slide Time: 14:25)

$$v_y = - \left[\sqrt{2xu} \cdot \frac{df}{d\eta} \cdot \frac{\partial \eta}{\partial x} + \frac{1}{2} \sqrt{\frac{2u}{x}} f \right]$$

$$v_y = \frac{1}{2} \sqrt{\frac{2u}{x}} \left[\eta \frac{df}{d\eta} - f \right]$$

$$v_x = U \frac{df}{d\eta}$$

equation as we have seen before is $\text{del } v_x \text{ del } x$, so I can substitute the expression for v_y in here, the expressions for v_x in here, all these, the remaining terms can also be evaluated which I am not showing in in here but it is given in the text.

(Refer Slide Time: 14:56)

$$v_x = U \frac{df}{d\eta} \rightarrow v_x \left(\frac{\partial v_x}{\partial x} \right) + v_y \left(\frac{\partial v_x}{\partial y} \right) = v \left(\frac{\partial^2 v_x}{\partial y^2} \right)$$

So I will leave that out and what it turns out, what it would result in is this as my governing equation. So this is going to be the governing equation.

(Refer Slide Time: 15:18)

$$v_x = U \frac{df}{d\eta}$$

$$2 \frac{d^3 f}{d\eta^3} + f \frac{d^2 f}{d\eta^2} = 0$$

The major thing that one should first see is this is an O D E.

(Refer Slide Time: 15:24)

$$2 \frac{d^3 f}{d\eta^3} + f \frac{d^2 f}{d\eta^2} = 0 \quad \text{ODE}$$

So we are successful in transforming this P D E to O D E by invoking the

(Refer Slide Time: 15:36)

The image shows a hand pointing to a whiteboard with the following handwritten equations and steps:

- Top equation: $\left[\sqrt{2x} u \cdot \frac{df}{d\eta} \cdot \frac{\partial \eta}{\partial x} + \frac{1}{2} \sqrt{\frac{2u}{x}} f \right]$
- Middle equation (boxed): $v_y = \frac{1}{2} \sqrt{\frac{2u}{x}} \left[\eta \frac{df}{d\eta} - f \right]$
- Left equation (boxed): $v_x = u \frac{df}{d\eta}$
- Transformation step: $v_x \left(\frac{\partial v_x}{\partial x} \right) + v_y \left(\frac{\partial v_x}{\partial y} \right) = \nu \left(\frac{\partial^2 v_x}{\partial y^2} \right)$
- Bottom equation (boxed): $2 \frac{d^3 f}{d\eta^3} + f \frac{d^2 f}{d\eta^2} = 0$ ODE

definition, by invoking a stream function by using, through a use of a combination variable eta that contains both x and y and a judicious selection of the, judicious selection of the, of the expression of eta

(Refer Slide Time: 15:56)

from an order of magnitude analysis enables us to convert the p d e to an o d e. However if you look at the P D E, look at the O D E, it's non-linear O D E of higher order terms. So even though we could get an expression, a neat governing equation, ordinary differential equation for the growth of boundary layer for the simplest possible case which is flow over a flat plate, it is still impossible, not possible to obtain a closed form solution. So even though we have the governing equation, we have the, we know what are the boundary conditions, a solution to this is not possible using analytical methods. So numerical methods will have to be used,

was used by, by a researcher named as Howarth and what he has presented is, he solved this equation numerically and presented a table containing, in the column, the first column is values of eta, corresponding values of f, the next column contains the value of f prime which is d f d eta, f double prime and so on.

So looking at the table, the numerical solution of the governing equation with appropriate boundary conditions you generate the results table. But the results table in itself is quite informative and it would give us, give us a form, a compact form of the growth of the boundary layer. Or in other words, the first thing that we started our, this exercise is to obtain, to obtain the relationship of delta as a function of x. So this table can now be used to obtain this functional form of delta in terms of x, that's what we would see next. So we are, we are starting with this equation, the governing equation. We also know that eta is defined as, and we have seen the expressions of v f to be equals d f d eta and the expressions for v y to be equals half, these are the expressions that we have seen. So we will use this later on.

(Refer Slide Time: 18:47)

$$2 \frac{d^3 f}{d \eta^3} + f \frac{d^2 f}{d \eta^2} = 0$$

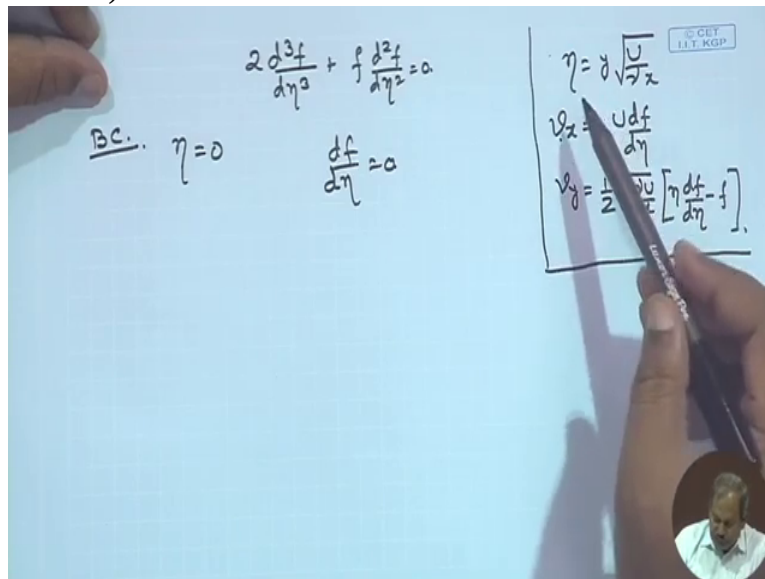

$$\eta = y \sqrt{\frac{U}{2 \nu x}}$$

$$v_x = U \frac{df}{d \eta}$$

$$v_y = \frac{1}{2} \sqrt{\frac{\nu U}{x}} \left[\eta \frac{df}{d \eta} - f \right]$$

We also understand that the boundary conditions to solve this equation are, at eta equals zero, that means eta equals zero means y equals zero, at y equals zero we understand that v x is going to be equal to zero. So if v x is zero, then d f d eta must be equal to zero. I will repeat it once again. At eta equals zero, the first condition, at the liquid solid interface that means at y equals zero, the velocity in the x direction due to no-slip condition must be equal to zero. So if velocity in the x direction is zero at eta equals zero which essentially tells me that d f d eta would be equal to zero. So d f d eta would be zero, that's my boundary condition. I also understand

(Refer Slide Time: 19:42)

The image shows a whiteboard with handwritten mathematical equations. The equations are:

$$2 \frac{d^3 f}{d\eta^3} + f \frac{d^2 f}{d\eta^2} = 0$$

BC. $\eta = 0$ $\frac{df}{d\eta} = 0$

$$\eta = \delta \sqrt{\frac{U}{\nu} x}$$
$$v_x = \frac{U}{\delta} \frac{df}{d\eta}$$
$$v_y = \frac{1}{2} \frac{U}{\delta} \left[\eta \frac{df}{d\eta} - f \right]$$

A small circular inset in the bottom right corner of the whiteboard shows a man's face.

that due to the same no-slip condition, not only v_x would be zero at η equals zero, v_y would also have to be zero at η equals zero. So when you have a no-slip condition, both components of velocity, that is v_x and v_y would be zero.

(Refer Slide Time: 20:00)

So if both v_x and v_y to be zero, then I, from the expression of v_x I have obtained that the necessary boundary condition is f' or rather $\frac{df}{d\eta}$ to be equal to zero. Now let's look at the expression of v_y to see what would be the no-slip condition on v_y would give me the value of either f , f' or f'' to be used as a boundary condition to solve this problem. So let's look at the v_y .

(Refer Slide Time: 20:30)

$$2 \frac{d^3 f}{d\eta^3} + f \frac{d^2 f}{d\eta^2} = 0$$

BC. $\eta = 0$ $\frac{df}{d\eta} = 0$

$$\eta = y \sqrt{\frac{U}{\nu}}$$

$$v_x = U \frac{df}{d\eta}$$

$$v_y = \frac{1}{2} \sqrt{\frac{U}{\nu}} \left[\eta \frac{df}{d\eta} - f \right]$$

At eta equals zero that means at y equals zero, I understand that this is zero since my v x is zero which I have already obtained. So at v y to be zero, this, since this is zero, this term must also be zero. So it's simply going to be

(Refer Slide Time: 20:50)

$$2 \frac{d^3 f}{d\eta^3} + f \frac{d^2 f}{d\eta^2} = 0$$

BC. $\eta = 0$ $f = \frac{df}{d\eta} = 0$

$$\eta = y \sqrt{\frac{U}{\nu}}$$

$$v_x = U \frac{df}{d\eta}$$

$$v_y = \frac{1}{2} \sqrt{\frac{U}{\nu}} \left[\eta \frac{df}{d\eta} - f \right]$$

not only the gradient of f with respect to eta is zero at eta equals zero which directly can be seen from the expression of v x, the requirement that v y will also have to be zero and since d f d eta is already zero it must also be zero. So the boundary condition, no-slip boundary condition would be f equals zero and d f d eta is also equals zero. And the other boundary condition, when eta is infinity, when eta is infinity that means y to be very large and when y is very large, v x approaches or v x becomes equal to u. So at a point when eta tends to infinity which physically represents a point far from the solid plate, the velocity of the,

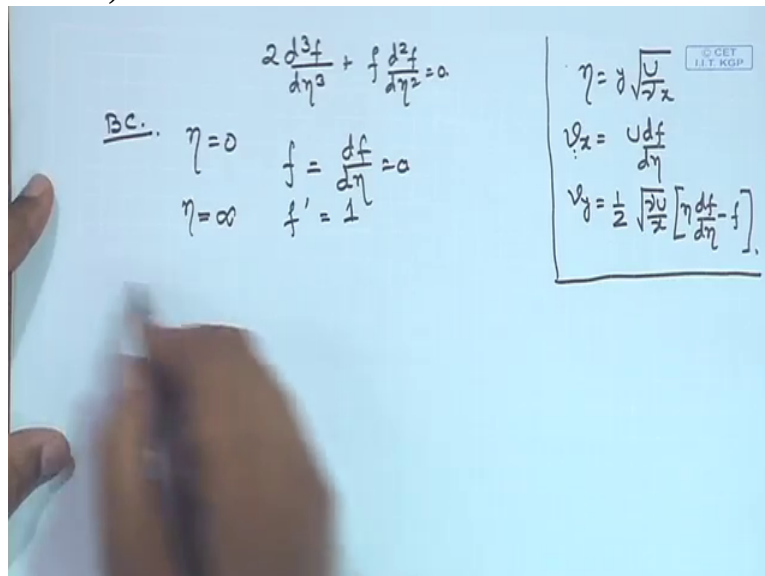

velocity of the fluid, velocity of the fluid at that point would simply be equal, would simply be equal

(Refer Slide Time: 21:55)

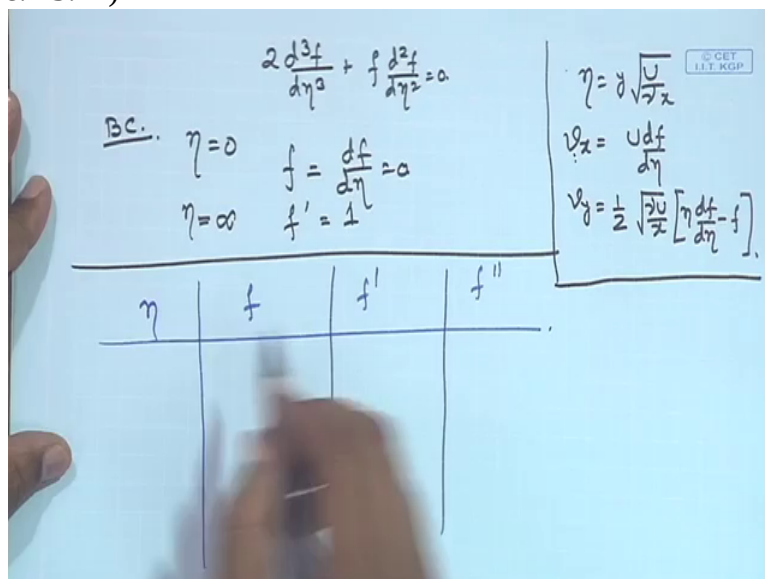

to the freestream velocity. So the form of the equation for v_x would tell you that $\frac{df}{d\eta}$ since v_x is equal to u times $\frac{df}{d\eta}$, since v_x and u are equal at that point, you simply have $\frac{df}{d\eta}$ to be equal to one which would constitute the other boundary condition to solve the problem, to solve the O D E. So for this third order O D E, now we have three conditions. One is the no-slip, that is η equals zero, both f and f' are equal to zero and at the other end when we are far from the flat plate, since v_x is equal to u , f' is equal to one. So these are three boundary conditions which Howarth has used in order to obtain a numerical solution of the governing differential equation. So at η equals infinity, f' is going to be equal to one.

(Refer Slide Time: 22:59)

Now the table that he has provided is eta then f then f prime, f double prime. I will

(Refer Slide Time: 23:14)

only list some of the values in here.

(Refer Slide Time: 23:18)

The rest you should be able to see in your textbook and I would only write those terms which are going to be relevant for our subsequent analysis. But he has, he has given a detailed list of values of f , f double prime and f , f prime and f double prime for different values of η . But I would list only some of the values, 4 or 5 values of this table.

(Refer Slide Time: 23:46)

$2 \frac{d^3 f}{d\eta^3} + f \frac{d^2 f}{d\eta^2} = 0$

BC. $\eta = 0$ $f = \frac{df}{d\eta} = 0$
 $\eta = \infty$ $f' = 1$

$\eta = \delta \sqrt{\frac{U}{\nu x}}$
 $v_x = U \frac{df}{d\eta}$
 $v_y = \frac{1}{2} \sqrt{\frac{\nu U}{x}} \left[\eta \frac{df}{d\eta} - f \right]$

η	f	f'	f''
0			

So this turns to be zero. This is zero and this would be point 3 3 2. And

(Refer Slide Time: 23:54)

$2 \frac{d^3 f}{d\eta^3} + f \frac{d^2 f}{d\eta^2} = 0$

BC. $\eta = 0$ $f = \frac{df}{d\eta} = 0$
 $\eta = \infty$ $f' = 1$

$\eta = \delta \sqrt{\frac{U}{\nu x}}$
 $v_x = U \frac{df}{d\eta}$
 $v_y = \frac{1}{2} \sqrt{\frac{\nu U}{x}} \left[\eta \frac{df}{d\eta} - f \right]$

η	f	f'	f''
0	0	0	0.332

5 point 0, 3 point 2 8 3 2 9, 0 point 9 9 1 5 5 and 0 point 0 1 5 9 1 and some other values

(Refer Slide Time: 24:09)

$2 \frac{d^3 f}{d\eta^3} + f \frac{d^2 f}{d\eta^2} = 0$

BC. $\eta = 0$ $f = \frac{df}{d\eta} = 0$
 $\eta = \infty$ $f' = 1$

$\eta = \delta \sqrt{\frac{U}{\nu x}}$
 $v_x = U \frac{df}{d\eta}$
 $v_y = \frac{1}{2} \sqrt{\frac{\nu U}{x}} \left[\eta \frac{df}{d\eta} - f \right]$

η	f	f'	f''
0	0	0	0.332
5.0	3.28329	0.99155	0.01591

which we would subsequently use in a tutorial class Almost 1, this is almost 1, Ok.

(Refer Slide Time: 24:32)

$2 \frac{d^3 f}{d\eta^3} + f \frac{d^2 f}{d\eta^2} = 0$

BC. $\eta = 0 \quad f = \frac{df}{d\eta} = 0$
 $\eta = \infty \quad f' = 1$

$\eta = \delta \sqrt{\frac{U}{\nu x}}$
 $v_x = U \frac{df}{d\eta}$
 $v_y = \frac{1}{2} \sqrt{\frac{\nu U}{x}} \left[\eta \frac{df}{d\eta} - f \right]$

η	f	f'	f''
0	0	0	0.332
5.0	3.28329	0.99155	0.01591
8.0	6.27923	~ 1.0	0.00001
8.4	6.67923	~ 1.0	0.000001

Let's look at these values. These are from the numerical solution of Howarth. So if you look at

(Refer Slide Time: 24:46)

$2 \frac{d^3 f}{d\eta^3} + f \frac{d^2 f}{d\eta^2} = 0$

BC. $\eta = 0 \quad f = \frac{df}{d\eta} = 0$
 $\eta = \infty \quad f' = 1$

$\eta = \delta \sqrt{\frac{U}{\nu x}}$
 $v_x = U \frac{df}{d\eta}$
 $v_y = \frac{1}{2} \sqrt{\frac{\nu U}{x}} \left[\eta \frac{df}{d\eta} - f \right]$

NUM. SOLN
HOWARTH

η	f	f'	f''
0	0	0	0.332
5.0	3.28329	0.99155	0.01591
8.0	6.27923	~ 1.0	0.00001
8.4	6.67923	~ 1.0	0.000001

the definition of v_x , you understand that v and v_x to be equal to u , f' has to be equal to 1. So the definition of v_x

(Refer Slide Time: 25:05)

$2f \frac{d^3f}{d\eta^3} + f^2 \frac{d^2f}{d\eta^2} = 0$

BC. $\eta = 0$ $f = \frac{df}{d\eta} = 0$
 $\eta = \infty$ $f' = 1$

$\eta = y \sqrt{\frac{U}{\nu x}}$
 $v_x = U \frac{df}{d\eta}$
 $v_y = \frac{1}{2} \sqrt{\frac{\nu U}{x}} \left[\eta \frac{df}{d\eta} - f \right]$

$v_x \sim U$
 $f' \sim 1$

tells you that in order for the velocity to approach the freestream velocity, to be equal to the freestream velocity, the value of $df/d\eta$ must be equal to 1. Now if you recall the definition of

(Refer Slide Time: 25:21)

the edge of the boundary layer or the thickness of the boundary layer, we have seen that it is at point at which the velocity reaches 99 percent of the freestream velocity. So let's see where we have this 99 percent. It's at this point. So at this point, the f' is about 99 percent, so therefore v_x by U is equal to point 99 and therefore it reaches 99 percent of the freestream velocity. And when does it happen; when η is equal to ϕ . So I will write that η equals ϕ where f' is equal to 1 can be written as

(Refer Slide Time: 26:05)

$2\eta \frac{d^3f}{d\eta^3} + f \frac{d^2f}{d\eta^2} = 0$

BC. $\eta=0$ $f = \frac{df}{d\eta} = 0$
 $\eta=\infty$ $f' = 1$

NUM. SOL. HOWARTH

η	f	f'	f''
0	0	0	0.332
5.0	3.28329	0.99155	0.01591
8.0	6.27923	~ 1.0	0.00001
8.4	6.67923	~ 1.0	0.000001

$\eta = \delta \sqrt{\frac{U}{\nu x}}$
 $v_x = U \frac{df}{d\eta}$
 $v_y = \frac{1}{2} \sqrt{\frac{\nu U}{x}} \left[\eta \frac{df}{d\eta} - f \right]$

$v_x \sim U$
 $f' \sim 1$

$\eta = 5 [f' = 1]$

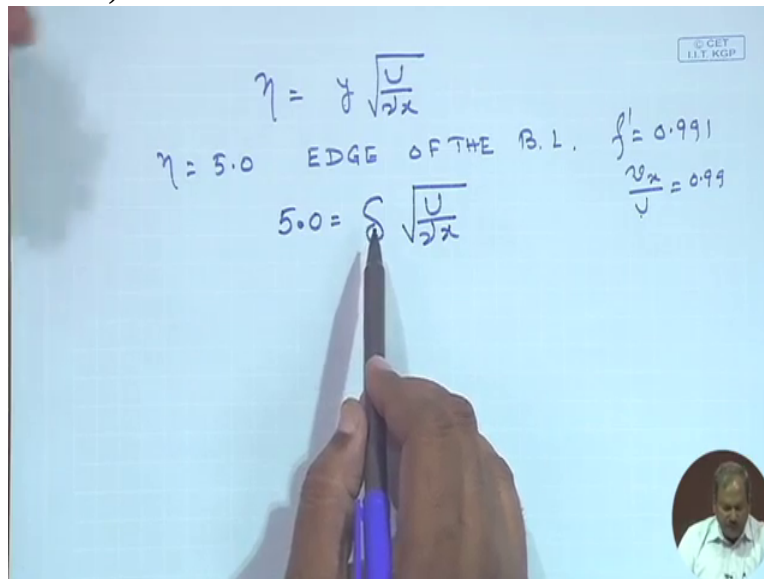

the edge of the boundary layer, can be taken as the edge of the boundary layer; so let's see how does that help us. We understand that by definition eta is y root over u by nu x and eta

(Refer Slide Time: 26:21)

$\eta = \delta \sqrt{\frac{U}{\nu x}}$

equals 5 can be taken as the edge of the boundary layer. So if that is so then at that point, when eta is 5 point 0, this y would simply become equal to delta where delta is the thickness of the boundary layer. Once again, for value of eta we have seen f prime is equal to point 9 9 1, that is the velocity v x by u is equal to point 9 9. So velocity reaches 99 percent of the freestream velocity and at that point y must be equal to, y must be equal to delta.

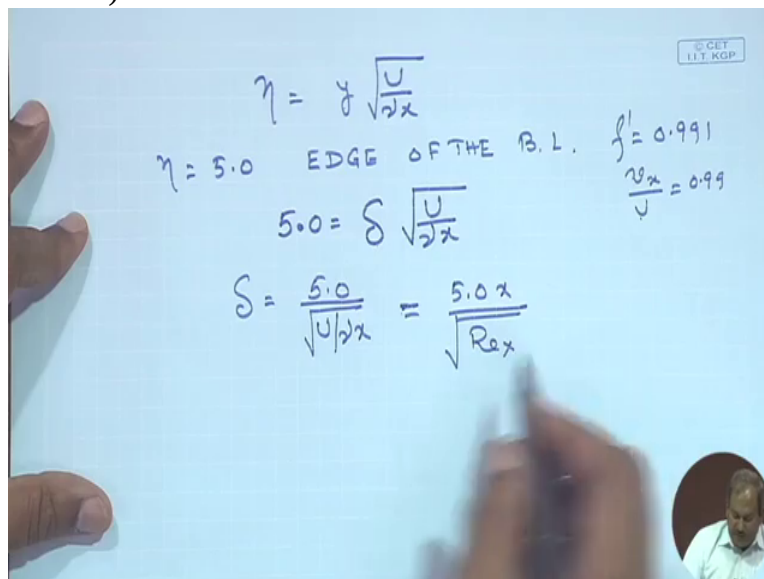

(Refer Slide Time: 27:03)

$\eta = \gamma \sqrt{\frac{U}{\nu x}}$
 $\eta = 5.0$ EDGE OF THE B.L. $f' = 0.991$
 $5.0 = \delta \sqrt{\frac{U}{\nu x}}$ $\frac{U}{\nu x} = 0.99$

So you have an expression for delta from here as 5 point 0 by root over u by nu x which can be slightly modified, slightly changed. This is r e x, it's just a reorganization of the terms and nothing else.

(Refer Slide Time: 27:23)

$\eta = \gamma \sqrt{\frac{U}{\nu x}}$
 $\eta = 5.0$ EDGE OF THE B.L. $f' = 0.991$
 $5.0 = \delta \sqrt{\frac{U}{\nu x}}$ $\frac{U}{\nu x} = 0.99$
 $\delta = \frac{5.0}{\sqrt{\frac{U}{\nu x}}} = \frac{5.0 x}{\sqrt{Re_x}}$

So what you get is delta to be equal to 5 point x by root over r e x. So this term, this expression

(Refer Slide Time: 27:34)

The image shows a whiteboard with handwritten mathematical equations. At the top, the equation $\eta = \gamma \sqrt{\frac{U}{\nu x}}$ is written. Below it, $\eta = 5.0$ is written, followed by the text "EDGE OF THE B.L.". To the right, the values $f' = 0.991$ and $\frac{v_x}{U} = 0.99$ are written. The next equation is $5.0 = \delta \sqrt{\frac{U}{\nu x}}$. This is followed by the derivation $\delta = \frac{5.0}{\sqrt{U/\nu x}} = \frac{5.0x}{\sqrt{Re_x}}$. The final equation, $\delta = \frac{5.0x}{\sqrt{Re_x}}$, is circled in black. A small circular inset in the bottom right corner shows a man speaking.

tells you what is the thickness of the boundary layer at a given axial position So if you have the growth of the boundary layer, if you fix the actual position which is x , you know exactly from this closed form equation what is going to be the δ at that point. So we have, we have achieved one of our goals, that is to obtain the thickness of the boundary layer at any given axial position.

Let us quickly

(Refer Slide Time: 28:05)

go through, look at some other important parameter which the engineers would like to have which is to obtain, what is the shear stress exerted by the moving fluid on the plate or in other words what is the wall shear stress. Can we use the numerical solution of Howarth to obtain

such a closed form solution for the wall shear stress as well? So we quickly do that. The wall shear stress, wall shear stress is simply, which I denote by τ_w is $\mu \frac{\partial v_x}{\partial y}$ at y equals zero which can be written

(Refer Slide Time: 28:51)

A hand is writing the equation $\tau_w = \mu \frac{\partial v_x}{\partial y} \Big|_{y=0}$ on a whiteboard. The whiteboard has a small logo in the top right corner that reads "© CET I.I.T. KGP".

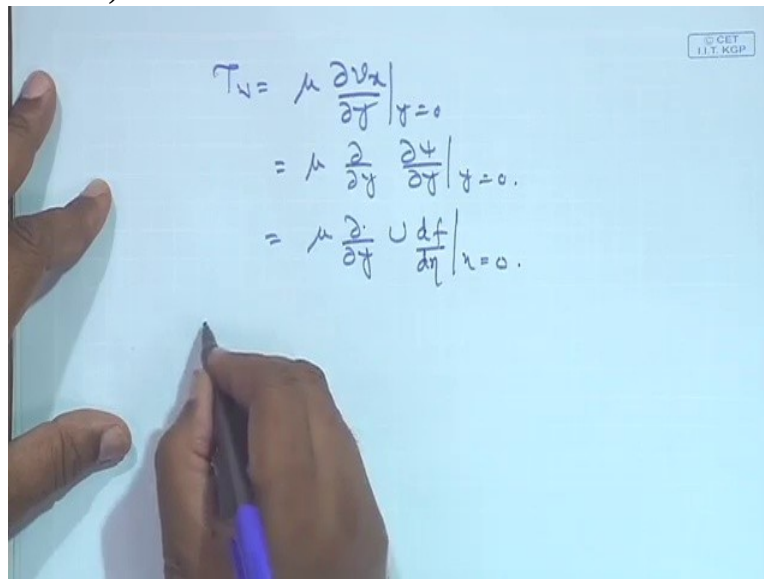

as $\frac{\partial \chi}{\partial y}$ Instead of v_x it is $\frac{\partial \chi}{\partial y}$ at y equals zero. Now if I bring in

(Refer Slide Time: 29:00)

A hand is writing two equations on a whiteboard. The first equation is $\tau_w = \mu \frac{\partial v_x}{\partial y} \Big|_{y=0}$ and the second equation is $= \mu \frac{\partial}{\partial y} \frac{\partial \psi}{\partial y} \Big|_{y=0}$. The whiteboard has a small logo in the top right corner that reads "© CET I.I.T. KGP".

instead of y , the concept of η , the combination variable, it is $\frac{\partial}{\partial \eta} \frac{\partial u}{\partial \eta}$ at η equals zero. So after

(Refer Slide Time: 29:16)

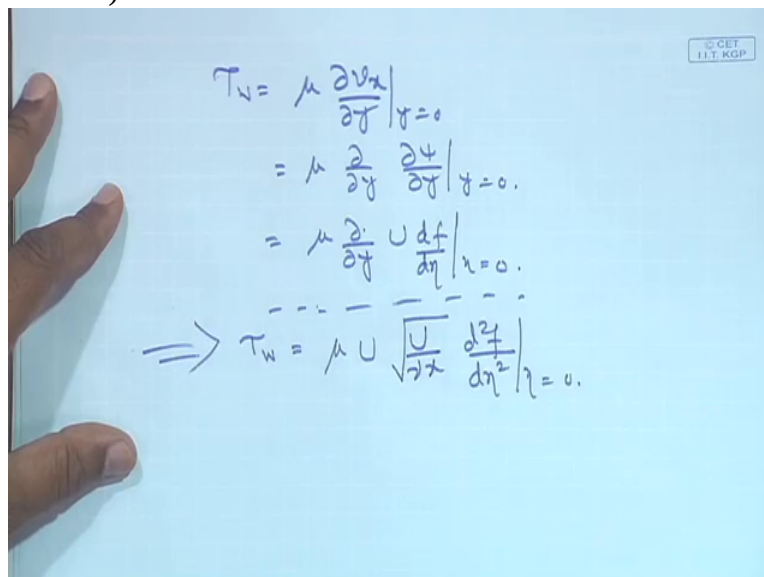

A hand is writing the following equations on a light blue grid background:

$$\begin{aligned}\tau_w &= \mu \left. \frac{\partial v_x}{\partial y} \right|_{y=0} \\ &= \mu \frac{\partial}{\partial y} \left. \frac{\partial \psi}{\partial y} \right|_{y=0} \\ &= \mu \frac{\partial}{\partial y} \left. U \frac{df}{d\eta} \right|_{\eta=0}.\end{aligned}$$

a bit of substitution which you would be able to see in your text, it would simply be equals mu times u root over u by mu x times d 2 f by d eta square at eta equals zero. So this is the expression for wall shear

(Refer Slide Time: 29:36)

A hand is writing the following equations on a light blue grid background:

$$\begin{aligned}\tau_w &= \mu \left. \frac{\partial v_x}{\partial y} \right|_{y=0} \\ &= \mu \frac{\partial}{\partial y} \left. \frac{\partial \psi}{\partial y} \right|_{y=0} \\ &= \mu \frac{\partial}{\partial y} \left. U \frac{df}{d\eta} \right|_{\eta=0} \\ \Rightarrow \tau_w &= \mu U \left. \frac{U}{\sqrt{2x}} \frac{d^2 f}{d\eta^2} \right|_{\eta=0}.\end{aligned}$$

stress And the only thing unknown here is what is the, what is the number d 2 f by d eta square

(Refer Slide Time: 29:48)

$$\tau_w = \mu \left. \frac{\partial v_x}{\partial y} \right|_{y=0}$$

$$= \mu \frac{\partial}{\partial y} \left. \frac{\partial \psi}{\partial y} \right|_{y=0}$$

$$= \mu \frac{\partial}{\partial y} \left. U \frac{df}{d\eta} \right|_{\eta=0}$$

$$\Rightarrow \tau_w = \mu U \frac{U}{\sqrt{2x}} \left. \frac{d^2 f}{d\eta^2} \right|_{\eta=0}$$

at eta equals zero. I bring in this, so d 2 f

(Refer Slide Time: 29:54)

$$\frac{d^3 f}{d\eta^3} + f \frac{d^2 f}{d\eta^2} = 0$$

BC. $\eta=0$ $f=0$ $f' = \frac{df}{d\eta} = 0$
 $\eta=\infty$ $f' = 1$

$v_x = U \frac{df}{d\eta}$
 $v_y = \frac{1}{2} \sqrt{\frac{\nu U}{x}} \left[\eta \frac{df}{d\eta} - f \right]$

$v_x \sim U$
 $f' \sim 1$
 $\eta = 5 [f' = 1]$

η	f	f'	f''
0	0	0	0.332
5.0	3.28329	0.99155	0.0159

NUM. SOL. HOWARTH

by d eta square which is nothing but f double prime, for the value of eta to be, at eta equal to zero, f double prime is simply equals point 3 3 2. So the numerical value of this is simply equals point 3 3 2 from the numerical solution of Howarth. So I will bring in this point 3 3 2 over here and what would I get at, since at eta equals zero f double prime to be equals point 3 3 2, what you would get,

(Refer Slide Time: 30:27)

$$\begin{aligned} \tau_w &= \mu \frac{\partial^2 v_x}{\partial y^2} \Big|_{y=0} \\ &= \mu \frac{\partial^2}{\partial y^2} \frac{\partial \phi}{\partial y} \Big|_{y=0} \\ &= \mu \frac{\partial^2}{\partial \eta^2} U \frac{df}{d\eta} \Big|_{\eta=0} \end{aligned}$$

$$\Rightarrow \tau_w = \mu U \sqrt{\frac{U \rho}{x}} \left(\frac{d^2 f}{d\eta^2} \Big|_{\eta=0} \right)$$

$\eta=0 \quad f'' = 0.332$

tau w to be equals point 3 3 2 u times root over rho mu u by x equals point 3 3 2 rho u square by root over r e x.

(Refer Slide Time: 30:44)

$$\begin{aligned} \tau_w &= \mu \frac{\partial^2 v_x}{\partial y^2} \Big|_{y=0} \\ &= \mu \frac{\partial^2}{\partial y^2} \frac{\partial \phi}{\partial y} \Big|_{y=0} \\ &= \mu \frac{\partial^2}{\partial \eta^2} U \frac{df}{d\eta} \Big|_{\eta=0} \end{aligned}$$

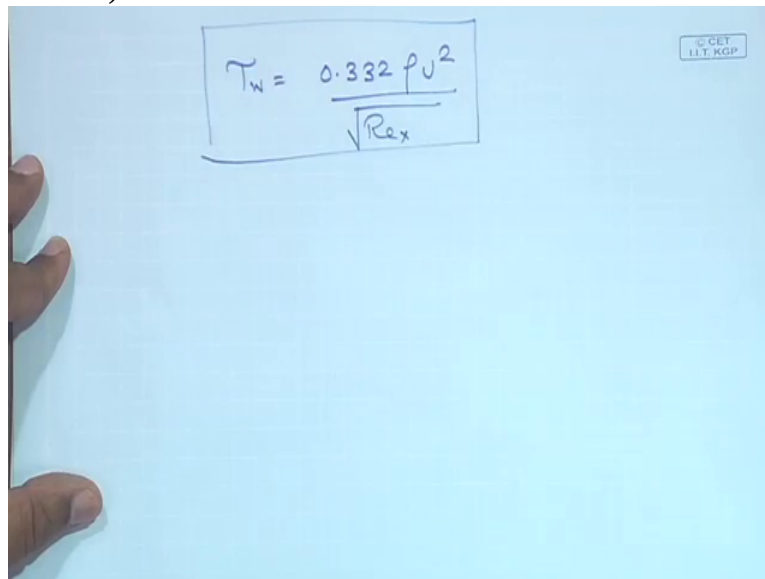

$$\Rightarrow \tau_w = \mu U \sqrt{\frac{U \rho}{x}} \left(\frac{d^2 f}{d\eta^2} \Big|_{\eta=0} \right)$$

$\eta=0 \quad f'' = 0.332$

$$\tau_w = 0.332 U \sqrt{\rho \mu U / x} = \frac{0.332 \rho U^2}{\sqrt{Re_x}}$$

So once again I write here the expression of tau w to be equals point 3 3 2 rho u square where u is the freestream velocity by r e x, that is another compact expression for

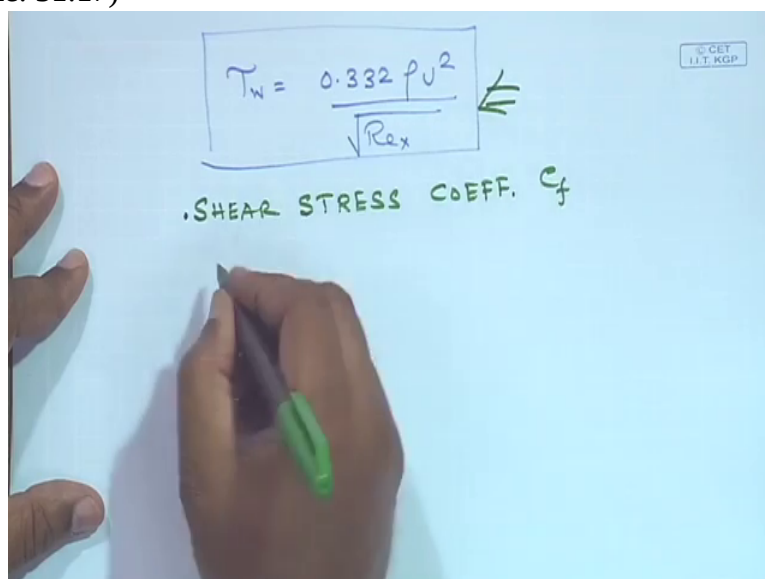

(Refer Slide Time: 31:01)

A hand-drawn equation on a light blue grid background. The equation is $\tau_w = \frac{0.332 \rho U^2}{\sqrt{Re_x}}$. The equation is enclosed in a hand-drawn rectangular box. In the top right corner of the grid, there is a small logo that reads "© CET I.I.T. KGP".

the wall shear stress and sometimes we define a shear stress coefficient which is traditionally denoted by c_f .

(Refer Slide Time: 31:17)

A hand-drawn equation on a light blue grid background, identical to the one in the previous slide. Below the equation, the text ".SHEAR STRESS COEFF. c_f " is written in green. A hand holding a green marker is visible at the bottom, pointing towards the text. In the top right corner of the grid, there is a small logo that reads "© CET I.I.T. KGP".

By definition, c_f is wall shear stress by the dynamic pressure and therefore if you bring in the expression of τ_w in here, what you would get is $0.664 \sqrt{Re_x}$. So the three equations, three conditions, three expressions that we have obtained

(Refer Slide Time: 31:40)

$$\tau_w = \frac{0.332 \rho U^2}{\sqrt{Re_x}}$$

.SHEAR STRESS COEFF. C_f

$$C_f = \frac{\tau_w}{\frac{1}{2} \rho U^2} = \frac{0.664}{\sqrt{Re_x}}$$

are through this exercise, are these three. One is the first is an expression of

(Refer Slide Time: 31:51)

$$\tau_w = \frac{0.332 \rho U^2}{\sqrt{Re_x}}$$

.SHEAR STRESS COEFF. C_f

$$C_f = \frac{\tau_w}{\frac{1}{2} \rho U^2} = \frac{0.664}{\sqrt{Re_x}}$$
$$\delta = \frac{5.0x}{\sqrt{Re_x}}$$

the boundary layer thickness The second is an expression of the wall shear stress and the third which is just by definition more commonly known as the shear stress coefficient, these two are equivalent. These two are equivalent, an expression for the shear stress coefficient which is point 6 6 4 by root over r e x. So one can see then that through the

(Refer Slide Time: 32:18)

use of Navier–Stokes equation, boundary layer approximation, identification of the appropriate boundary conditions, evaluation of a combination variable which combines both y and x into η through an order of magnitude analysis, introduction of stream function and dimensionless stream function, all these complicated steps are necessary to convert the Navier–Stokes equation inside the boundary layer that too for two dimensional flow inside the boundary layer to an o d e but even that o d e is, is non-linear o d e and it is higher order as well.

So analytical solution was possible and one had to use numerical solution techniques to, to obtain the results which is for any value of η , what are the values of f , f' and f'' . And since we know how would, how would the velocity v_x , velocity in the x direction behave when we reach the edge of the boundary layer and what would be the gradient of velocity at y equals zero, that is on the solid plate, we would get, we finally got expressions of δ as a function of x and τ_w or c_f , the friction coefficient as a function of x and other flow parameters, the physical property of the fluid and so on. So for the simplest possible case, it is complicated, Ok.

So this method can be used for flow over a flat plate but this approach is, cannot be used for any complicated geometries. This is only limited to laminar flow. So if the fluid is, if the fluid is undergoing, or in turbulent flow this expression cannot be used. This is for a zero pressure gradient flow. If you have a pressure gradient present in the system because of the, since it is not a flat plate, then approach cannot be used. So we have a solution but the solution is for the simplest possible case and it cannot be termed as a general solution or easy to use

approach in solving the boundary layer parameters for any type of flow on any geometry or any type of surface, any geometric surface.

So there has to be a generalized method which is easy to use and is not restricted by all these constraints. So what we would do in the next few classes after I solve one problem, a tutorial class on this is to, is to show you a generalized approach in which it would be far more easier to handle situations which are not so-called the ideal systems, flow over a flat plate. It would be approximate but it would still allow us to compute these numbers, the growth of the boundary layer, the value of the wall shear stress and so on in a much more effective and easy to use way. So that is what we would do in the next class.
