Lecture – 41
Flow Measurement

Welcome to lecture 41. So, this is week 9 and we will start today flow measurement. So, in this week, we will talk about measurement of flow measurement of liquid flow or measurement of gas flow is important in many chemical process industries. It is particularly important when you look at operations or manufacturing processes that happen continuously.

For continuous operating processes there will always the flow of raw materials, products, waste utilities, etcetera and it is very important that we will be able to measure as accurately as possible the flow of liquid streams or gas streams in several chemical process industries.

(Refer Slide Time: 01:30)

Flow Measurement: Motivation

The measurement and control of liquid or gas flow is vital to many process industries such as oil, power, bulk chemicals, water and waste treatment, etc.

The manufacturing processes that run as continuous operations involve the movement of raw materials, products, and waste through pipes and ducts throughout the process. These fluids can range from thick oils with high density to very light gasses.

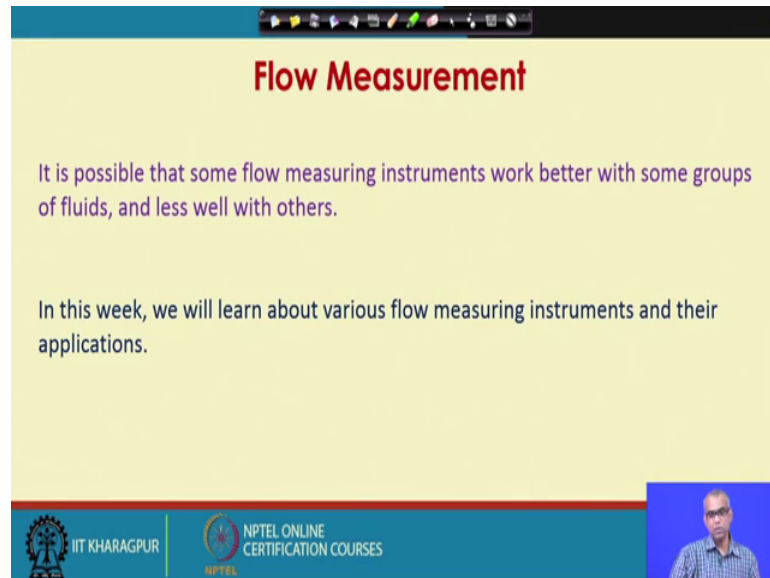

It is important that we know exactly how much fluid is passing through a point at any given point for a safe and economic operation.

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES

So, the motivations for flow measurement are as follows the measurement and control of liquid or gas flow is vital to many process industries such as oil, power, bulk chemicals, water and waste treatment, etcetera. The manufacturing processes that run as continuous operations involve the movement of raw materials products waste through pipes and ducts throughout the process these fluids can range from thick oils with high density to

very light gases. It is important that you know exactly how much fluid is passing through a point at any given point for a safe and economic operation.

(Refer Slide Time: 02:22)

Flow Measurement

It is possible that some flow measuring instruments work better with some groups of fluids, and less well with others.

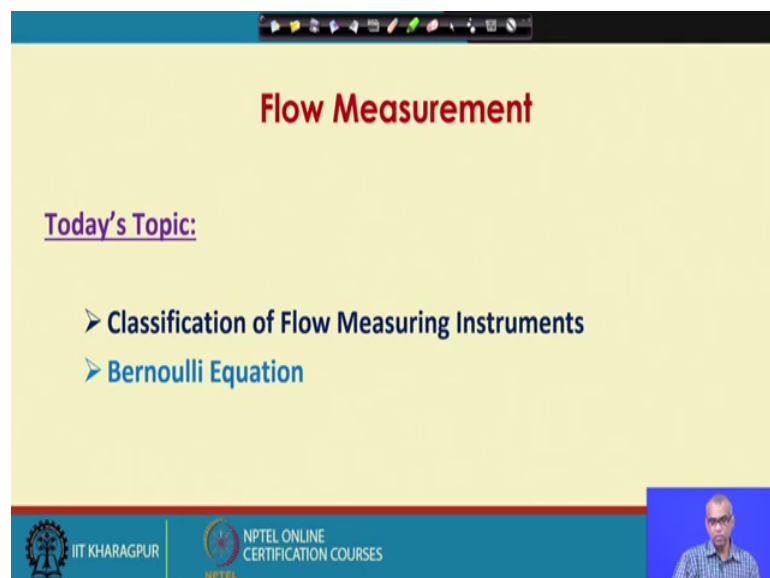

In this week, we will learn about various flow measuring instruments and their applications.

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES

The slide features a yellow background with a red title. At the bottom, there are logos for IIT Khharagpur and NPTEL, and a small video inset of the presenter.

It is possible that some flow measuring instruments work better with some groups of fluids and less well with others, it is obvious because you will be handling fluids which will vary from say very thick to very light. So, there will always be flow measuring instruments which will work better with some group of fluids and less well with others in this week we will learn about various flow measuring instruments and their applications.

(Refer Slide Time: 03:02)

Flow Measurement

Today's Topic:

- Classification of Flow Measuring Instruments
- Bernoulli Equation

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES

The slide features a yellow background with a red title. At the bottom, there are logos for IIT Khharagpur and NPTEL, and a small video inset of the presenter.

So, today we will classify various flow measuring instruments and then we will talk about an important principle on which a certain class of flow measuring instruments are designed this is known as Bernoulli's principles. So, we will talk about Bernoulli's equation.

(Refer Slide Time: 03:33)

Flow Measuring Instruments: Classification

A. Flow of fluids in closed pipes:

- 1. Constant Area – Variable Pressure Drop Meters:**
 - Orifice plate
 - Venturi tube
 - Flow nozzle
 - Pitot tube
- 2. Variable Area - Constant Pressure Drop Meter:**
 - Rotameter
- 3. Velocity Measurement Type:**
 - Hot-wire Anemometer
- 4. Mass Flow Measurement Type:**
 - Coriolis
- 5. Positive Displacement Type:**
 - Nutating disc

B. Flow of fluids in open channel: Weir type

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES

This is how we classify various flow measuring instruments again this is not the only classification that is available, I have been saying this for all measuring instruments because there are various ways of classifying the instruments into different categories and what you see on the screen is one possible way of classifying the flow measuring instruments and we will follow this classification for the purpose of this course, broadly, I classify the flow measuring instruments into two categories one is flow of fluids in closed pipes another the flow of fluids in open channel. Of course, flow of fluids in closed pipes finds many more applications and under flow of fluids in closed pipes, we have classified various flow measuring instruments under two different categories.

First constant area variable pressure drop meters under this we will talk about orifice plate Venturi tube, Flow nozzle and Pitot tube, then we have variable area constant pressure drop meter and we will talk about rotameter third velocity measurement type we will talk about hot wire anemometer, then mass flow measurement type we will talk about Coriolis flow meter and then positive displacement type we will talk about Nutating disc.

Under flow of fluids in open channel we will talk about wire types flow meter.

(Refer Slide Time: 06:00)

Some Basic Principles: Average Rate of Flow

In a flow through pipe, the velocity of a fluid is the rate of flow of fluid particles in the pipe. The speed of particles in a fluid flow varies across the flow. At the walls, the velocity of the liquid particles is practically zero, and the particles will have the maximum velocity at the centre. Thus, the average rate of flow is used in flow calculations.

The units of flow velocity are: feet per second (fps), feet per minute (fpm), meters per second (mps), etc.

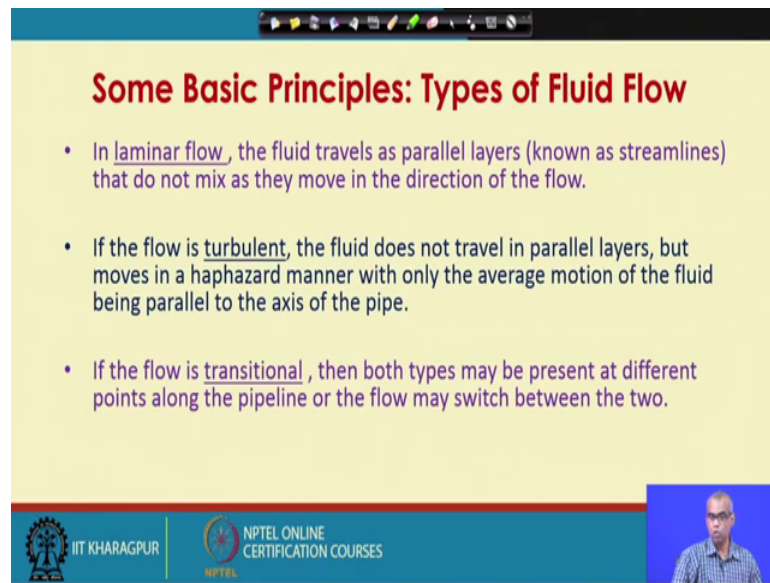

The units of flow rate: volume unit/time (m^3/s), mass unit/time (g/s)

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES

Let us go through some basic principles first average rate of flow in a flow through pipe, the velocity of a fluid is the rate of flow of fluid particles in the pipe. The speed of particles in a fluid flow varies across the flow. At the walls, the velocity of the liquid particles is practically zero, and the particles will have the maximum velocity at the centre. Thus, the average rate of flow is used in flow calculations.

The units of flow velocity are say feet per second or feet per minute meters per seconds etcetera. The units of flow rate if it is volumetric flow rate we will expressed as volume unit per times such as meter cube per second, if it is mass flow rate, we will express in mass unit per time such as gram per second.

(Refer Slide Time: 07:01)

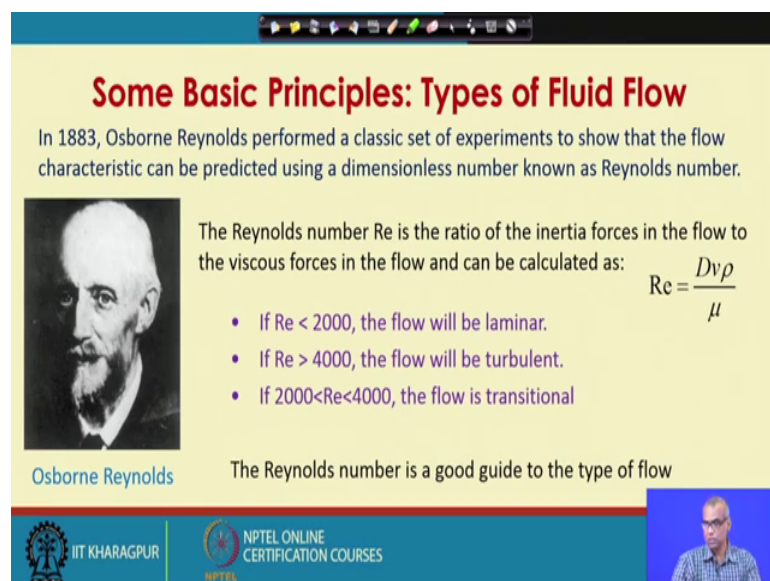

Some Basic Principles: Types of Fluid Flow

- In **laminar flow**, the fluid travels as parallel layers (known as streamlines) that do not mix as they move in the direction of the flow.
- If the flow is **turbulent**, the fluid does not travel in parallel layers, but moves in a haphazard manner with only the average motion of the fluid being parallel to the axis of the pipe.
- If the flow is **transitional**, then both types may be present at different points along the pipeline or the flow may switch between the two.

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES

Next we will talk about types of fluid flow in laminar flow the fluid travels as parallel layers known as stream lines that do not mix as they move in the direction of the flow. If the flow is turbulent the fluid does not travel in parallel layers, but most in a haphazard manner with only the average motion of the fluid being parallel to the axis of the pipe. If the flow is transitional, then both types may be present at different points along the pipeline or the flow may switch between the two.

(Refer Slide Time: 07:44)

Some Basic Principles: Types of Fluid Flow

In 1883, Osborne Reynolds performed a classic set of experiments to show that the flow characteristic can be predicted using a dimensionless number known as Reynolds number.

Osborne Reynolds

The Reynolds number Re is the ratio of the inertia forces in the flow to the viscous forces in the flow and can be calculated as:

$$Re = \frac{Dv\rho}{\mu}$$

- If $Re < 2000$, the flow will be laminar.
- If $Re > 4000$, the flow will be turbulent.
- If $2000 < Re < 4000$, the flow is transitional

The Reynolds number is a good guide to the type of flow

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES

In 1883 Osborne Reynolds performed a classic set of experiments to show that the flow characteristic can be predicted using a dimensionless number known as Reynolds number. The Reynolds number expressed as Re is the ratio of the inertia forces in the flow to the viscous forces in the flow and can be calculated as $Dv\rho$ divided by μ

Here D is the diameter of the pipe through which flow takes place v is the velocity ρ is the density of the fluid and μ is the viscosity if Reynolds number is less than 2000 the flow will be laminar if Reynolds number is greater than 4000, the flow will be turbulent and if the Reynolds number lies in between 2000 and 4000, the flow is transitional thus the Reynolds number is a good guide to the type of flow.

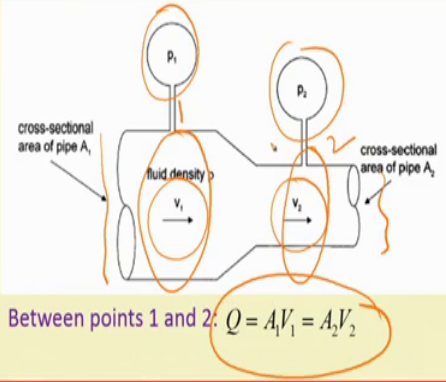

(Refer Slide Time: 09:05)

So, this schematically shows laminar flow see how the this fluid particles are moving in parallel with each other this is turbulent flow where it is all haphazard and this is transitional. So, you see a mixture of laminar and turbulent in transitional flow.

(Refer Slide Time: 09:52)

Flow Measurement: Continuity Equation

The continuity equation states that if the overall flow rate (Q) in a system is not changing with time, the flow rate in any part of the system is constant.

$$Q = VA$$

Q = volumetric flow rate, V = average velocity, A = cross-sectional area of the pipe.

Between points 1 and 2: $Q = A_1V_1 = A_2V_2$

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES

So, these are the velocity profile, now we will talk about continuity equation which plays a very important role in flow measurement. The continuity equation states that if the overall flow rate Q in a system is not changing with time the flow rate in any part of the system is constant. So, consider a flow through a pipe where the cross sectional area is changing from A_1 here to A_2 , here the velocity is V_1 , here the velocity is V_2 , here the pressure is P_1 here the pressure is P_2 , here we this is point 1 this is point 2. So, the velocity and pressure at point 1 are different from the velocity and pressure at point 2.

If the overall flow rate in the system is not changing between points 1 and 2 this relationship must hold true; that means, the volumetric flow rate Q is the product of cross sectional area and velocity. So, the volumetric flow rate Q is equal to cross sectional area and velocity product here which is same as the cross sectional area and velocity product here.

(Refer Slide Time: 12:12)

Flow Measurement: Continuity Equation: An Example

If a pipe goes from a 9-cm diameter to 6-cm diameter and the velocity in the 9-cm section is 2.0 m/s, what is the average velocity in the 6-cm section?

$$Q = A_1 V_1 = A_2 V_2$$
$$\Rightarrow V_2 = \frac{A_1}{A_2} V_1 = 4.5 \text{ m/s}$$

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES

So, Q is $A_1 V_1$ equal to $A_2 V_2$ as an example, let us consider the pipe goes from 9 centimeter diameter to 6 centimeter diameter and the velocity in the 9 centimeter section is 2 meter per second what is the average velocity in the 6 centimeter per second.

So, here you have 9 centimeter diameter and the velocity is 2 meter per second here the diameter is 6 centimeter, we have to find out the velocity. So, this is a straightforward application of Q equal to $A_1 V_1$ equal to $A_2 V_2$. So, you can find out V_2 as A_1 by A_2 into V_1 . So, A_1 is πd^2 divided by 4 A_2 is πd^2 divided by 4 you can also write πr^2 divided by πr^2 into V_1 .

So, A_1 can be found out as $\pi 9^2$ divided by 4 similarly A_2 can be found out as $\pi 6^2$ divided by 4 and V_1 is given as 2 meter per second put all these numbers take care of units and you will get V_2 as 4.5 meter per second, remember, this is in centimeter, but these are in meter per second. So, you must take care of units.

(Refer Slide Time: 14:39)

Constant Area – Variable Pressure Drop Meter

Orifice plate Venturi tube Flow nozzle Pitot tube

Bernoulli Equation

IIT KHARAGPUR NPTEL ONLINE CERTIFICATION COURSES 12

Next, we will start our discussion on constant area variable pressure drop meters under this category. We will talk about orifice plate Venturi tube, Flow nozzle and Pitot tube to understand the working of constant area variable, pressure drop meter; we must talk about Bernoulli's equation first. So, first we talk about Bernoulli's equation or Bernoulli's principle.

(Refer Slide Time: 15:14)

Bernoulli Equation

The Bernoulli equation is an equation for flow based on the law of conservation of energy. This is the starting point for understanding the principle of the variable pressure flow-meter.

IIT KHARAGPUR NPTEL ONLINE CERTIFICATION COURSES

The Bernoulli's equation is an equation for flow based on the law of conservation of energy; this is the starting point for understanding the principles of the variable pressure flow meter. So, Bernoulli's equation is basically a statement of conservation of energy.

(Refer Slide Time: 15:38)

Bernoulli Equation

The Bernoulli equation gives the relationship among fluid velocity (V), fluid absolute pressure (P), and height (h) above some reference line for a fluid flowing through a pipe of varying cross-section.

$$\frac{P_1}{\rho g} + \frac{V_1^2}{2g} + h_1 = \frac{P_2}{\rho g} + \frac{V_2^2}{2g} + h_2$$

Sum of (pressure energy + kinetic energy + potential energy) = constant

Assumption: incompressible fluids, steady flow along a streamline, no energy loss due to friction, no heat transfer.

The slide includes a diagram of a pipe with fluid flowing from left to right. Two points, 1 and 2, are marked on the pipe. Point 1 is at a higher elevation and has a larger cross-section, while point 2 is at a lower elevation and has a smaller cross-section. Arrows indicate the flow direction and velocity vectors v_1 and v_2 . Vertical lines from the pipe to a horizontal reference line indicate heights h_1 and h_2 .

Logos for IIT KHARAGPUR and NPTEL ONLINE CERTIFICATION COURSES are visible at the bottom of the slide.

The Bernoulli's equation gives the relationship among fluid velocity fluid absolute pressure and height above some reference line for a fluid flowing through a pipe of varying cross section. So, consider the flow of a liquid through a pipe whose cross section is varying. So, cross section here and cross section here are different.

The height of this pipe is measured from this reference line. So, this point is the height from h_1 from this reference line and this point is at a height of h_2 from this reference line Bernoulli's equation says that between points A 1 points 1 and 2 this is point 1 and this is point 2 the sum of pressure energy kinetic energy and potential energy is constant at point 1 the pressure energy is P_1 by ρg at point 1 the kinetic energy is V_1 square by $2g$ and the potential energy can be expressed as potential head h_1

So, P_1 by ρg plus V_1 square by $2g$ plus h_1 is equal to P_2 by ρg plus V_2 square by $2g$ plus h_2 . So, sum up pressure energy plus kinetic energy plus potential energy equal to constant here P_1 is absolute pressure V_1 is the fluid velocity ρ is the density of the fluid g is acceleration due to gravity and h is height from the reference line this Bernoulli's equation is applicable to incompressible fluids steady flow along a streamline

no energy loss due to friction and no heat transfer. So, remember some of pressure energy kinetic energy and potential energy is equal to constant.

(Refer Slide Time: 18:52)

Bernoulli Equation: Flow Measurement

Since the pipe is horizontal, $h_1 = h_2$, and Bernoulli equation reduces to:

$$\frac{P_1 - P_2}{\rho} = \frac{V_2^2 - V_1^2}{2}$$

Apply continuity equation between points 1 and 2: $Q = A_1 V_1 = A_2 V_2$

Combine continuity equation with Bernoulli equation:

$$Q = A_2 V_2 = \frac{A_2}{\sqrt{1 - \left(\frac{A_2}{A_1}\right)^2}} \sqrt{\frac{2(P_1 - P_2)}{\rho}}$$

Thus change in flow-rate through a restriction can be measured in terms of differential pressure across it.

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES

Now, consider the flow through a pipe of varying cross section and the pipe is horizontal at point 1 here at point 2 here. So, since the pipe is horizontal h_1 is equal to h_2 the h_1 and h_2 as we shown in the previous slide. So, they are same. So, then if I apply the Bernoulli's equation; that means, if I apply this equation P_1 by ρg plus V_1 square by $2 g$ plus h_1 equal to P_2 by ρg plus V_2 square by $2 g$ plus h_2 between one and 2 and h_1 and h_2 are same what I get is P_1 by ρg plus V_1 square by $2 g$ equal to P_2 by ρg plus V_2 square by $2 g$.

So, if you rearrange this you will get this P_1 by P_2 by ρ equal to V_2 square minus V_1 square by 2 if we apply continuity equation between point 1 and point 2, I can write as $A_1 V_1$ here and $A_2 V_2$ here they will be same as the volumetric flow rate Q .

Now, if I combine this 2 I can write Q equal to $A_2 V_2$ and an expression of V_2 can be obtained from this and I will be able to write Q equal to $A_2 V_2$ equal to A_2 by square root of 1 minus A_2 by one whole square into square root of 2 into P_1 minus P_2 by ρ

Thus change in flow rate through a restriction can be measured in terms of differential pressure across it see P_1 minus P_2 . So, what I did is I am considering a flow through a horizontal pipe of varying cross section. So, h_1 equal to h_2 apply the Bernoulli's

equation between point 1 and point 2 I get this at point 1 and 2 I apply continuity equation I get this I combine these 2 equation and I get this.

And note this equation here on A 2 these are all related to the dimension of the pipe. So, the volumetric flow rate is related to the pressure difference P 1 minus P 2 across the flow restriction note here is a flow restriction because of change in this dimension.

(Refer Slide Time: 22:41)

Bernoulli Equation: Flow Measurement

In practice we add a correction factor C_d (discharge coefficient – depends on Reynolds Number).

$$Q = A_2 V_2 = \frac{A_2}{\sqrt{1 - \left(\frac{A_2}{A_1}\right)^2}} \sqrt{\frac{2(P_1 - P_2)}{\rho}}$$

$$Q_a = Q C_d = \frac{C_d A_2}{\sqrt{1 - \left(\frac{A_2}{A_1}\right)^2}} \sqrt{\frac{2(P_1 - P_2)}{\rho}}$$

Velocity of approach factor: $\frac{1}{\sqrt{1 - \left(\frac{A_2}{A_1}\right)^2}}$

Flow coefficient: $\frac{C_d}{\sqrt{1 - \left(\frac{A_2}{A_1}\right)^2}}$

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES

In practice, we had a correction factor c_d known as discharge coefficient which depends on Reynolds number.

So, this is the equation you got by combining Bernoulli's equation and the continuity equation. So, this is the idealized volumetric flow rate in practice we will add a correction factor known as C_d ; we called it stretch coefficient and Q_a , Q actual will be this Q multiplied by the discharge coefficient C_d . So, this is the expression I get for actual volumetric flow rate through a pipe where we have a flow restriction P_1 minus P_2 is the pressure drop across the flows restriction velocity of approach factor is this term.

So, you look at this. So, velocity approach is one by square root of $1 - \frac{A_2}{A_1}$ whole square, similarly the flow coefficient is this term C_d by $1 - \frac{A_2}{A_1}$ whole square; square root for laboratory experiments a u tube manometer may be used to measure the differential pressure head Δh because we know $P_1 - P_2$ equal to $\rho g \Delta h$.

(Refer Slide Time: 24:28)

Bernoulli Equation: Flow Measurement

For laboratory experiments, a U-tube manometer may be used to measure the differential pressure head Δh as: $P_1 - P_2 = \rho g \Delta h$

$Q_2 = QC_d = \frac{C_d A_2}{\sqrt{1 - \left(\frac{A_2}{A_1}\right)^2}} \sqrt{\frac{2(P_1 - P_2)}{\rho}} = \frac{C_d A_2}{\sqrt{1 - \left(\frac{A_2}{A_1}\right)^2}} \sqrt{2g \Delta h}$

For industrial practice, usually a diaphragm is used for measuring the pressure drop. A diaphragm with one pressure on each side will deform according to the pressure difference.

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES

So, this is this is the pipe of varying cross section. So, you have a flow restriction here. So, u tube manometer can be used to determine the differential pressure that happens between point 1 and point 2. So, this $P_1 - P_2$ can be replaced as $\rho g \Delta h$ this ρ and this ρ will get cancelled and what you will get is Q a is this. So, this part will be this part because $P_1 - P_2 = \rho g \Delta h$.

However for industrial practice use of a u tube manometer may not be convenient and for industrial practice usually a diaphragm is used for measuring the pressure drop. A diaphragm with one pressure on each side will deform according to the pressure difference, we have talked about diaphragm pressure measuring instrument while discussing pressure measuring instruments.

(Refer Slide Time: 26:30)

Rangeability and Turndown Ratio of Flow Meters

Rangeability:
Rangeability refers to the minimum and maximum measurable flow-rates with specified accuracy. For example, if the maximum flow-rate is 100 L/min and the minimum flow-rate is 10 L/min, the rangeability is 10 – 100.

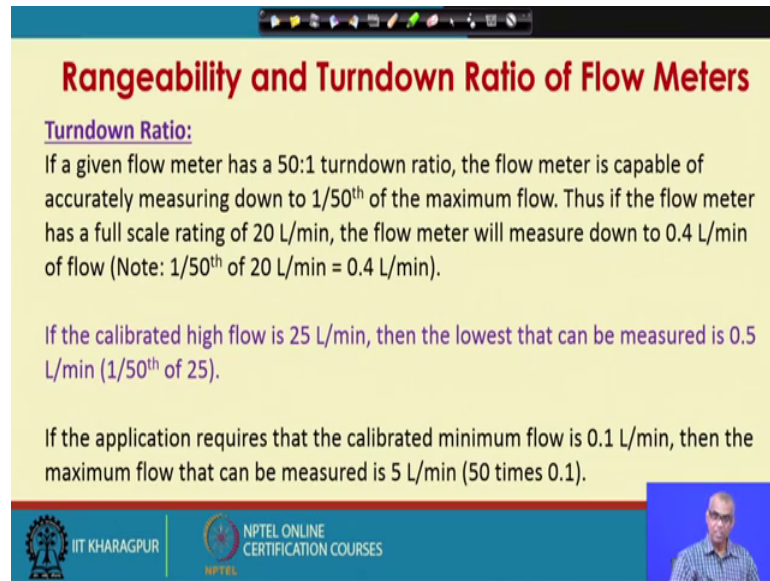

Turndown Ratio:
Turndown conveys the same information as rangeability but in a slightly different way. Turndown is the ratio of maximum flow to minimum flow. For the same flow-meter we used in the rangeability example above, the turndown ratio would be 100:10.

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES

Now, we talk about two important aspects of flow measuring instruments they are known as Rangeability and turn down ratio of flow meters rangeability refers to the minimum and maximum measurable flow rates with specified accuracy. For example, if the maximum flow rate is 100 liter per minute and the minimum flow rate is 10 liter per minute the rangeability 10 to 100 turndown ratio conveys the same information as rangeability, but in a slightly different way turndown is the ratio of maximum flow to minimum flow.

So, basically turn down ratio is maximum flow rate divided by minimum flow rate for the same flow meter we used in the rangeability example above; that means, whose maximum flow is 100 liter per minute and minimum flow rate is 10 liter per minute the turndown ratio will be 100 is 100 is to 10, remember, these minimum and maximum measurable flow rates we are talking about the flow rates which matches with the specified accuracy.

(Refer Slide Time: 28:12)

Rangeability and Turndown Ratio of Flow Meters

Turndown Ratio:
If a given flow meter has a 50:1 turndown ratio, the flow meter is capable of accurately measuring down to 1/50th of the maximum flow. Thus if the flow meter has a full scale rating of 20 L/min, the flow meter will measure down to 0.4 L/min of flow (Note: 1/50th of 20 L/min = 0.4 L/min).

If the calibrated high flow is 25 L/min, then the lowest that can be measured is 0.5 L/min (1/50th of 25).

If the application requires that the calibrated minimum flow is 0.1 L/min, then the maximum flow that can be measured is 5 L/min (50 times 0.1).

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES

Let us talk about turn down ratio a bit more if a given flow meter has a 50 is to 1, turn down ratio the flow meter is capable of accurately measuring down to 1 by 50th of the maximum flow thus if the flow meter has a full scale rating of 20 liter per minute the flow meter will measure down to 0.4 liter per minute of flow because 1 by 50th of 20 liter per minute is 0.4 liter per minute.

If the calibrated high flow is 25 liter per minute then the lowest that can be measured is 0.5 liter per minute why 0.5 liter per minute because it is 1/50th of 25 if the application requires that the calibrated minimum flow is point 1 liter per minute then the maximum flow rate that can be measured is 50 times point 1 liter per minute that is 5 liter per minute. So, this is how you can interpret the turndown ratio.

(Refer Slide Time: 29:48)

Now, look at the diagram on the screen in this figure this h is equal to 7.2 meter the area at point 2 is 0.2 meter square and the area at point 3 is 0.3 meter square g is given as 9.80 meter per second square, we have to find out the pressure at point 2. So, we have to find out what is P 2. So, I will give you the sketch of the solution procedure.

First what we will do is let us try to find out the velocity at point 3 let us try to find out first at velocity at point 3. So, find out velocity at point 3 what we can do is you can write the Bernoulli's equation between point 1 and point 3 as P_1 by ρg plus 0 plus h equal to P_3 by ρg plus V_3 square by 2 g plus 0 note the reference line.

Note that $P_3 = P_1 = 1$ atmosphere this equation will allow you to calculate V_3 and V_3 will be able to calculate as 12.12 meter per second note that the value of h is 7.5 meter. So, we have got V_3 , once I have got V_3 , I will be able to get V_2 by using continuity equation as $Q_2 = A_2 V_2 = A_3 V_3$ A_2 / A_3 is given. So, this will allow you to compute V_2 as 7.27 meter per second.

So, I have now calculated V_2 I have now calculated V_3 , now apply, now apply Bernoulli's equation between point 2 and 3 if I apply Bernoulli's equation between point 2 and 3 I will write P_2 by ρg plus V_2 square by 2 g plus 0 because reference line equal to P_3 by ρg plus V_3 square by 2 g plus 0. So, this is between point 2 and point 3 between points 2 and 3.

So, once you put in all the values you will be able to calculate P_2 because you know P_3 there is one atmosphere. So, P_3 you know is one atmosphere. So, that is equal to 101.3 Pascal; calculate Pascal. So, V_2 V_3 we have found out. So, you will be able to find out P_2 .

So, P_2 you can calculate as 148.32 kilo Pascal, but this will be absolute. So, if I am going to find out gauge you have to subtract 101.3 kilo Pascal that most the equation. So, that will be equal to approximately 47 kilo Pascal gauge.

So, this is how you can solve this problem. So, what I what you do is first you basically apply the Bernoulli's equation first between point 1 and point 3 to calculate V_3 once you get V_3 you use continuity equation between point 2 and 3 and calculate V_2 . So, at this stage I have P_1 , P_3 , V_2 , V_3 ; now between point 2 and 3, I use Bernoulli's equation and then calculate P_2 .

So, I stopped today here and in the next class we will talk about examples of pressure measuring instruments that make use of Bernoulli's equation such as orifice meter by Venturi tube, etcetera.
