Lecture - 37
Introduction to Linear Programming (Contd.)

Welcome to lecture 37. This is week 8, and we are talking about Linear Programming Problems. In our previous lecture we have discussed how to formulate a linear programming problem. In this lecture we will discuss graphical solution method for linear programming problem. A linear programming problem in two variables can be conveniently solved using graphical methods. So, in this lecture we will see how to solve a linear programming problem in two variables using graphical methods.

(Refer Slide Time: 00:53)

The slide is titled "Introduction to Linear Programming" in red text. It is divided into two columns. The left column is headed "Week 8:" and lists three items: "Formulation of linear programming models" (with a green checkmark), "Graphical solution" (with a green arrow), and "Linear programs in standard form" (with a green arrow). The right column is headed "Today's Topic:" and lists "Graphical solution" (with a green arrow). At the bottom left, there are logos for IIT Kharagpur and NPTEL Online Certification Courses. At the bottom right, there is a small video inset showing a man speaking.

So, linear programming problems in two variables can be very conveniently solved by graphical method and following at the steps to solve a linear programming problem using graphical method.

(Refer Slide Time: 00:56)

The image shows a presentation slide with a yellow background and a blue header. The title is 'Graphical Solution of Linear Programming Problem' in red. Below the title, there is a paragraph in purple text stating that linear programming problems in two variables can be solved by the graphical method. A numbered list of five steps follows. At the bottom, there are logos for IIT Kharagpur and NPTEL Online Certification Courses, and a small video inset of a man speaking.

Graphical Solution of Linear Programming Problem

Linear Programming problems in TWO variables can be very conveniently solved by Graphical Method.

1. Set up objective function and constraints in mathematical format
2. Plot the inequality constraints as equations
3. Identify the feasible solution space
4. Plot the objective function as straight line
5. Determine the optimum solution

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES

First set up objective function and constraints in mathematical format that means, formulate the linear programming problem. And we know that how to do that the objective function will be a linear equation in decision variables and all the constraints will be equality or inequality type again in decision variables.

Next we plot the inequality constraint as equations then you identify the feasible solution space which is defined by the constraints associated with the problem. Then you plot the objective function as a straight line it is a linear equation in decision variable, and then we determine the optimum solution.

So, these are the steps and you will see how this steps are followed to solve a linear programming problem in two variable using graphical method.

(Refer Slide Time: 02:17)

Graphical Solution of LPP: Feasible Region

When we plot each inequality as equation on the graph we get the feasible region.

If the inequality constraint corresponding to a constraint line is \leq type, then the region below the line in the first quadrant is feasible region for that constraint.

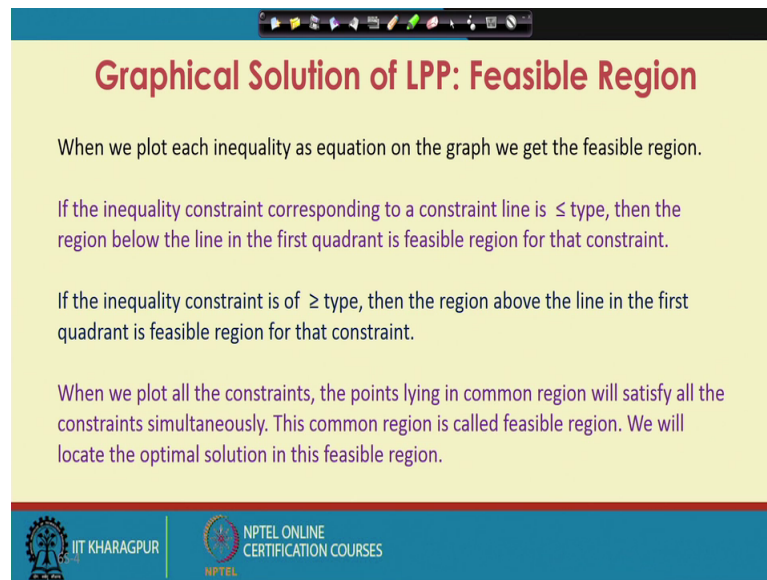

The slide features a hand-drawn graph on a coordinate system with axes labeled x_1 and x_2 . A straight line is drawn in the first quadrant, and the triangular region bounded by the axes and this line is shaded with blue diagonal lines. An arrow points from the text to this shaded region. To the right of the graph, there is a small blue symbol resembling a double tilde (\approx).

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES

So, let us first define the feasible region. When you plot each inequality as equation on the graph we get the feasible region. If the inequality constraint corresponding to a constraint line is less or equal to type then the region below the line in the first quadrant is feasible region for that constraint.

So, what do you mean is, suppose we have a linear programming problem in two variables x_1 and x_2 . Now, a constraint which is the linear type let us say I plot a constraint like this and this constraint is less or equal to type. So, the region below this line in the first quadrant is feasible region for this constraint that means, this shaded region is the feasible region for this constraint.

(Refer Slide Time: 03:50)

Graphical Solution of LPP: Feasible Region

When we plot each inequality as equation on the graph we get the feasible region.

If the inequality constraint corresponding to a constraint line is \leq type, then the region below the line in the first quadrant is feasible region for that constraint.

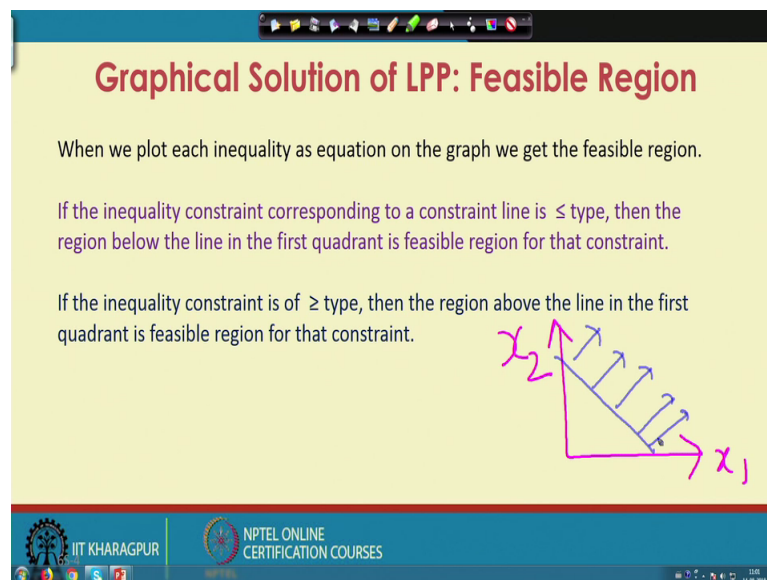

If the inequality constraint is of \geq type, then the region above the line in the first quadrant is feasible region for that constraint.

When we plot all the constraints, the points lying in common region will satisfy all the constraints simultaneously. This common region is called feasible region. We will locate the optimal solution in this feasible region.

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES

Similarly, if the inequality constraint is of greater or equal type, then the region above the line in the first quadrant is feasible region for that constraint.

(Refer Slide Time: 04:06)

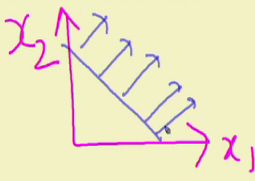

Graphical Solution of LPP: Feasible Region

When we plot each inequality as equation on the graph we get the feasible region.

If the inequality constraint corresponding to a constraint line is \leq type, then the region below the line in the first quadrant is feasible region for that constraint.

If the inequality constraint is of \geq type, then the region above the line in the first quadrant is feasible region for that constraint.

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES

So, again what do you mean is, if you have a constraint greater or equal to type then this is the region which is feasible for this particular constraint. When you plot all the constraints the points lying in common region will satisfy all the constraints simultaneously. This common region is called feasible region. We locate the optimal solution in this feasible region.

(Refer Slide Time: 04:45)

Example: Graphical Solution of LPP

A chemical company can make two types of products: Product-A and Product-B from the same raw material using the same processing equipment.

There are 40 hours of processing time and 120 kg of raw material available each day

How much A and B should be produced to maximize profits given processing time and materials constraints?

Product	Processing time required (hour/kg)	Raw material required (kg/kg)	Profit (Rs/kg)
A	1	4	40
B	2	3	50

The slide includes logos for IIT KHARAGPUR and NPTEL ONLINE CERTIFICATION COURSES, and a small video inset of a speaker.

Now, let us take an example and solve the problem using graphical method. The problem is as follows a chemical company can make two types of products product A and product B from the same raw material using the same processing equipment.

Let us consider such a situation exists, that given raw material a certain raw material, the chemical company can produce either product A or product B using the same processing equipment. The processing time required to produce 1 kg of product A is 1 hour, and the processing time required to produce 1 kg of product B is 2 hours. The raw material required to produce 1 kg of product A is 4 kg, and the raw material required to produce product B is 3 kg.

The profit associated with 1 kg of product A is rupees 40 and the profit associated with product B, 1 kg of product B is rupees 50. If there are 40 hours of processing time and 120 kg of raw material available each day how much of A and how much of B should be produced to maximize the profit. And we must respect the processing time and the materials constraint that means raw constraints and processing time and the constraints and raw materials.

So, this is the problem. So, now, would like to solve it using graphical method. So, first step is to formulate the problem.

(Refer Slide Time: 07:23)

Problem Formulation: Graphical Solution of LPP

Resource Availability:	40 hrs of processing time per day
	120 kg of raw material per day
Decision Variables:	x_1 = amount (kg) of Product-A to produce per day
	x_2 = amount (kg) of Product-B to produce per day
Objective Function:	Maximize $Z = 40x_1 + 50x_2$
	where Z = profit per day
Resource Constraints:	$1x_1 + 2x_2 \leq 40$ hours of processing time
	$4x_1 + 3x_2 \leq 120$ kg of raw materials
Non-Negativity Constraints:	$x_1 \geq 0; x_2 \geq 0$

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES

Let us look at resources available first 40 hours of processing time per day and 120 kg of raw materials per day. Let us choose the decision variables as x_1 equal to amount of product A to produce per day and amount of product B to produce per day we call it x_2 . So, my production schedule that is decision variables are x_1 equal to amount of product A to produce per day and x_2 equal to amount of product B to produce per day.

1 kg of product A gives me 40 rupees of profit, so x_1 kg of product A gives me $40 \times x_1$ amount of profit. Similarly 1 kg of product B gives a profit of rupees 50. So, x_2 kg of product B gives a profit of 50 into x_2 . So, the total profit is Z equal to $40 \times x_1$ plus $50 \times x_2$ per day. So, this is a objective function Z equal to $40 \times x_1$ plus $50 \times x_2$ and we need to maximize this.

So, now look at the constraints. Constraints here two explicit constraints, one is associated with 40 hours of processing time per day other is 120 kg of raw materials per day. So, first look at 40 hours of processing time per day.

Now, look at the table one more time. 1 kg of product A requires 1 hour of processing time and 1 kg of product B requires 2 hours of processing time. So, x_1 kg of product A requires x_1 hour processing time and x_2 kg product B required $2 \times x_2$ hours of processing time. So, the total processing time x_1 plus two x_2 must be less or equal to 40.

(Refer Slide Time: 09:34)

Problem Formulation: Graphical Solution of LPP

Resource Availability: 40 hrs of processing time per day
120 kg of raw material per day

Decision Variables: x_1 = amount (kg) of Product-A to produce per day
 x_2 = amount (kg) of Product-B to produce per day

Objective Function: Maximize $Z = 40x_1 + 50x_2$
where Z = profit per day

Constraints: $1x_1 + 2x_2 \leq 40$ hours of processing time
 $4x_1 + 3x_2 \leq 120$ kg of raw materials

Non-Negativity Constraints: $x_1 \geq 0; x_2 \geq 0$

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES

Similarly, you have constraints on raw materials 1 kg of product A requires 4 kg of raw materials. So, x 1 kg of product A requires 4 x 1 kg of raw materials and similarly x 2 kg of product B requires 3 x 2 kg raw materials. So, 4 x 1 plus 3 x 2 must be less or equal to 120 kg, which is available per day. So, these are two explicit constraints and then of course, there is non-negativity constraints because x 1 and x 2 cannot have negative values. So, x 1 is greater or equal to 0, x 2 is greater or equal to 0.

(Refer Slide Time: 11:05)

LPP: Feasible Solution

Maximize $Z = 40x_1 + 50x_2$

subject to:

- $x_1 + 2x_2 \leq 40$
- $4x_1 + 3x_2 \leq 120$
- $x_1, x_2 \geq 0$

A feasible solution does not violate any of the constraints.

Example:

- $x_1 = 5$ kg of A
- $x_2 = 10$ kg of B
- $Z = 40x_1 + 50x_2 = 700$

Processing time constraint check: $1(5) + 2(10) = 25 < 40$ hours

Raw material constraint check: $4(5) + 3(10) = 50 < 120$ kg

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES

So, this part represents the complete formulation maximize Z equal to $40x_1$ plus $50x_2$ subject to x_1 plus $2x_2$ less or equal to 40 , $4x_1$ plus $3x_2$ less or equal to 120 and x_1 is greater or equal to 0 x_2 is greater or equal to 0 .

A feasible solution will lie within the feasible region. These two constraints and these non-negativity constraints all together will define a feasible region. Any point within this feasible region will not violate any constraint; any point outside this feasible region will violate at least one constraint. For example, if I take x_1 equal to 5 and x_2 equal to 10 that means, x_1 equal to 5 kg of A and x_2 equal to 10 kg of B. So, let us look at x_1 equal to 5 and x_2 equal to 10 whether they violate the constraints or not. For x_1 equal to 5 and x_2 equal to 10 , the objective function is computed at 700 .

(Refer Slide Time: 12:17)

LPP: Feasible Solution

Maximize $Z = 40x_1 + 50x_2$

subject to:

$$\begin{aligned} x_1 + 2x_2 &\leq 40 \\ 4x_1 + 3x_2 &\leq 120 \\ x_1, x_2 &\geq 0 \end{aligned}$$

A feasible solution does not violate any of the constraints.

Example:

$$\begin{aligned} x_1 &= 5 \text{ kg of A} \\ x_2 &= 10 \text{ kg of B} \\ Z &= 40x_1 + 50x_2 = 700 \end{aligned}$$

Processing time constraint check: $1(5) + 2(10) = 25 < 40$ hours ✓

Raw material constraint check: $4(5) + 3(10) = 50 < 120$ kg ✓

$x_1 = 5$
 $x_2 = 10$

The slide also features logos for IIT KHARAGPUR and NPTEL ONLINE CERTIFICATION COURSES at the bottom, and a small video inset of a speaker in the bottom right corner.

Now, x_1 equal to 5 and x_2 equal to 10 you first put in this expression. So, x_1 equal to 5 and x_2 equal to 10 it gives x_1 plus $2x_2$ as 25 which is less than 40 . So, this is satisfied.

Similarly put x_1 equal to 5 and x_2 equal to 10 in the expression $4x_1$ plus $3x_2$ and you get that 50 which is less than 120 kg, so again satisfied. So, x_1 equal to 5 , x_2 equal to 10 lies within the feasible region it may be a feasible solution, but it is not an optimal solution not necessarily an optimal solution, you have to find out optimal solution, we will see how to do that.

(Refer Slide Time: 13:38)

LPP: Infeasible Solution

Maximize $Z = 40x_1 + 50x_2$

subject to: $x_1 + 2x_2 \leq 40$
 $4x_1 + 3x_2 \leq 120$
 $x_1, x_2 \geq 0$

An infeasible solution violates at least one of the constraints.

Example: $x_1 = 10$ kg of A
 $x_2 = 20$ kg of B
 $Z = 40x_1 + 50x_2 = 1400$

Processing time constraint check: $1(10) + 2(20) = 50 > 40$ hours

Handwritten notes: $x_1 = 10$, $x_2 = 20$, Infeasible, X

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES

Infeasible solution will violate at least one of the constraints. For example, let us take x_1 equal to 10 and x_2 equal to 20. The objective function you can compute as 1400 which is much higher than the previous value x_1 equal to 5 and x_2 equal to 10.

Now, let us check if the constraints are satisfied. So, let us first look at processing time constraint. So, put x_1 equal to 10, x_2 equal to 20 and you get $x_1 + 2x_2$ as 50 which is greater than 40. So, constraint is violated. So, this is infeasible. Note that the objective function associated with this solution is much higher but this is infeasible solution.

(Refer Slide Time: 14:56)

Graphical Solution of LPP: Coordinates

x_1 = amount (kg) of Product-A to produce per day
 x_2 = amount (kg) of Product-B to produce per day

Maximize $Z = 40x_1 + 50x_2$

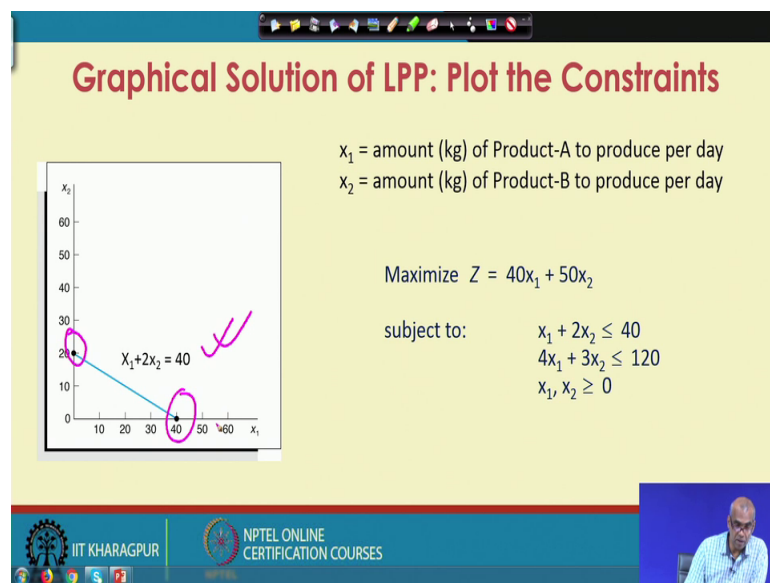

subject to: $x_1 + 2x_2 \leq 40$
 $4x_1 + 3x_2 \leq 120$
 $x_1, x_2 \geq 0$

A graph is shown with x_1 on the horizontal axis and x_2 on the vertical axis, both ranging from 0 to 60.

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES

So, now let us look at how do I solve this problem using graphical method. So, let us start plotting the constraints. So, first thing is look at the coordinates. So, we have x_1 equal to the amount of product A to produce per day as decision variable and x_2 equal to amount to product B to produce per day as decision variable. So, I have two decision variables, we can very conveniently solve using graphical method. So, I have this x_1 axis and x_2 axis. So, x_1 represent amount of product A to produce per day, similarly x_2 represent amount to product B to produce per day so, on this axis I will plot the constraints.

(Refer Slide Time: 15:52)

So, look at look at the first question $x_1 + 2x_2 \leq 40$. So, first we will plot this constraint as equation. So, I plot $x_1 + 2x_2 = 40$ is very easy to solve, very easy to plot here. So, look at this point this is $x_1 = 40$ and $x_2 = 0$, so satisfied. Similarly $x_1 = 0$ and $x_2 = 20$ again satisfied. So, I have plotted $x_1 + 2x_2 \leq 40$ constraint as an equation $x_1 + 2x_2 = 40$

Now, the region below this is the feasible region. Why? Because it is less or equal to type constraint.

(Refer Slide Time: 17:11)

So, the region below the line representing $x_1 + 2x_2 = 40$ is my feasible region. If you look at the figure the point A lies within the feasible region, but point B lies outside the region, so the point B is infeasible, point A is feasible.

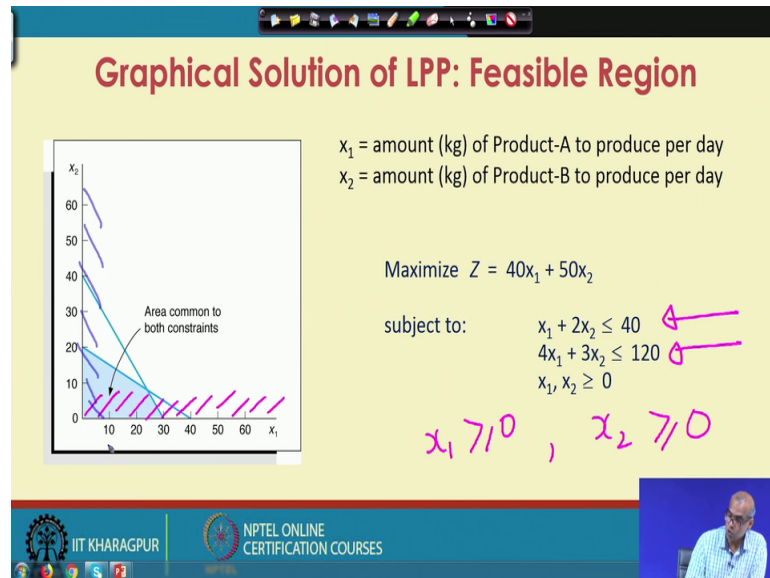

(Refer Slide Time: 17:42)

Next go to the second constraint $4x_1 + 3x_2 \leq 120$ again I plot $4x_1 + 3x_2 = 120$. I treat the inequality as equality and plot it. So, again it is very simple to plot consider $4x_1 + 3x_2 = 120$. So, if I put $x_2 = 0$ $x_1 = 30$, similarly if I put $x_1 = 0$ $x_2 = 40$, $3 \times 40 = 120$. Again the

inequality is less or equal to type. So, the region below the line represented by $4x_1 + 3x_2 \leq 120$ is feasible region. So, this is the feasible region, the shaded region is the feasible region.

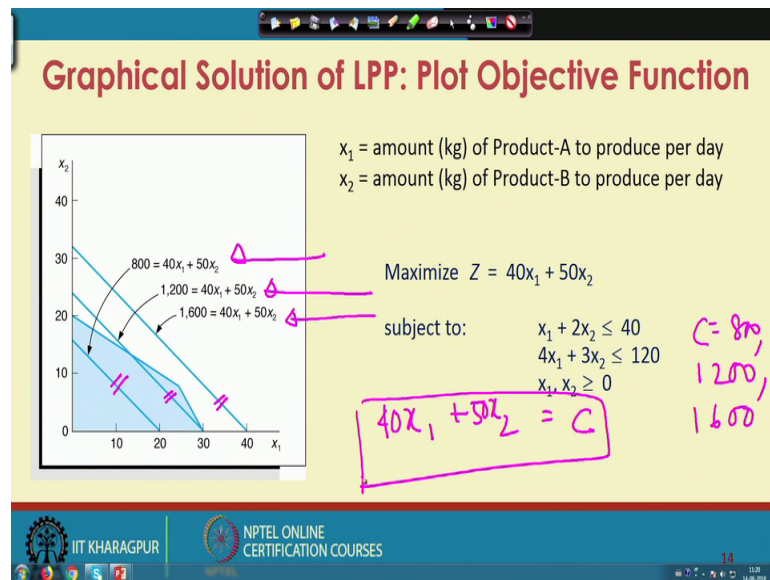

(Refer Slide Time: 19:03)

Now, let us look at the figure where we have now plotted both the constraints. So, there are two straight lines representing the two constraints $x_1 + 2x_2 \leq 40$ and $4x_1 + 3x_2 \leq 120$. Now, there are two more constraints $x_1 \geq 0$ and $x_2 \geq 0$. Note that this region is $x_1 \geq 0$ and this region is $x_2 \geq 0$. So, the axis x_1 and x_2 , the first quadrant is the feasible region for $x_1 \geq 0$ and $x_2 \geq 0$, these are non negativity constraints or implicit constraints.

Now, if you look at the area common to all the constraints which is shown here by this shaded region. This region is the feasible region for the problem. So, the non-negativity constraints $x_1 \geq 0$ and $x_2 \geq 0$ and the two constraints will together determine the feasible region as shown in the shaded region in the figure.

(Refer Slide Time: 21:12)

Now, let us plot the objective function objective function is $40x_1 + 50x_2$, Z equal to $40x_1 + 50x_2$ is my objective function. So, 3 different lines for objective functions are plotted here we are plotted $40x_1 + 50x_2$ equal to 800 as objective function. The next we have plotted $40x_1 + 50x_2$ equal to 1200, and then we have plotted $40x_1 + 50x_2$ equal to 1600. So, basically $40x_1 + 50x_2$ equal to C , some constraints C , here C equal to 800 in first case, then 1200 in second case, and 1600 in the third case.

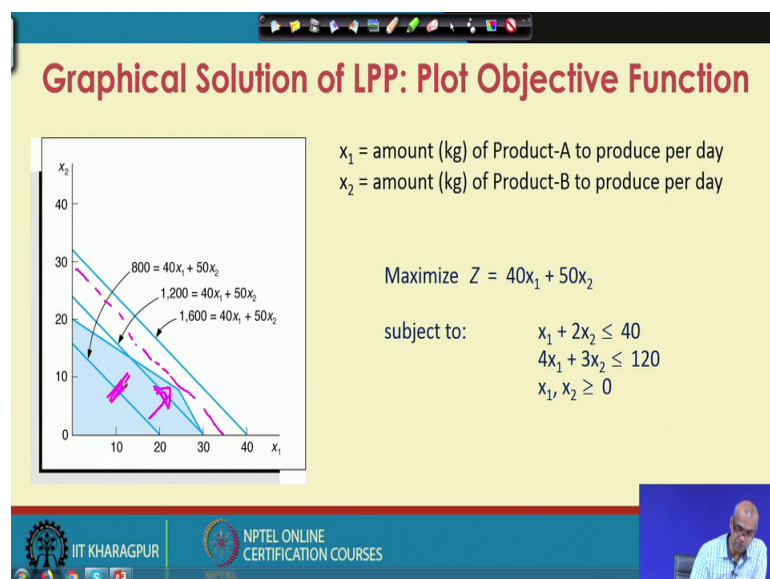

Note that with different values of C this equation $40x_1 + 50x_2$ equal to C we need two parallel lines. So, we get the objective functions as parallel lines. And we are trying to maximize the objective function. So, of course, we will choose that straight line among all the parallel lines, which gives me highest value for the objective function.

(Refer Slide Time: 23:42)

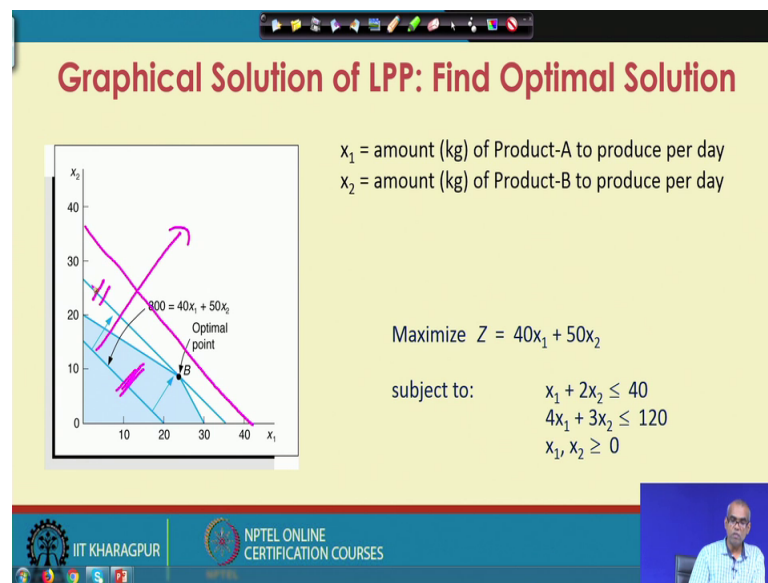

Now, in the figure shown this is the objective function line which has maximum value for the objective function 1600, but if you look at closely this line is outside the feasible region. So, this cannot be considered but what we see that if I go in this direction my objective function value is increasing objective function value increases from 800 to 1200, then 1600 it is a different story that in we need comes to 1600 we are outside the feasible region.

(Refer Slide Time: 24:36)

So, what we do is we start with, let us say this objective function line and slowly move in this direction, because you know if I moving in this direction my function value objective function value is increasing and then we look at that straight line which is parallel to this line and just touches a point on the feasible region because as the figure shows, as we move in the direction, in which objective function value is increasing I am slowly going out of the feasible region.

(Refer Slide Time: 25:17)

So, the situation that we will get is as follows. Now, look at the figure I am moving this objective function line in this direction. So, of the objective function value is increasing, I am always keeping the objective function parallel to this starting line. When I come to a point B I get the maximum value of the objective function which exists within the feasible region. There will be even higher value of the objective function. If I consider, another parallel line, line parallel to this but that is outside the feasible region. So, that will need to infeasible solution. But if you look at point B, the point B lies within the feasible region and gives maximum value of the objective function. So, point B is optimal.

(Refer Slide Time: 27:02)

Now, there are 3 corner points A, B and C in the feasible region apart from the point 0 0. So, apart from the point 0 0 origin we have 3 corner points A, B and C, in the feasible region point A, point B and point C. We have noted that the optimal solution is located at point B. Point A corresponds to x_1 equal to 0 and x_2 equal to 20, objective function value associated with these is 1000. Point C is associated with x_1 equal to 30 x_2 equal to 0 and the objective function value is 1200. Point B is associated with x_1 equal to 24 x_2 equal to 8 and Z equal to 1360. This is the maximum objective function value and this is the optimal solution.

One interesting thing to note is that in case of linear programming problem the solution will always lie in a corner point. In fact, the solution will always lie in one or more corner point when there is optimal solution more than one optimal solutions multiple optimal solutions. We will talk about that in the next class, but right now let us try to understand that the optimal solution will always lie in a corner point.

So, if you visit the corner points you can also find out the optimal solution. When we will talk about the simplex method, you will see that the simplex method is a smart way of visiting these corner points such that optimal solutions can be found out quickly. See one can always visit all the corner points, calculate the objective function values and then pick up which one is maximum or which one is minimum; where I am maximizing a problem here. So, I can visit all the corner points and choose the corner point

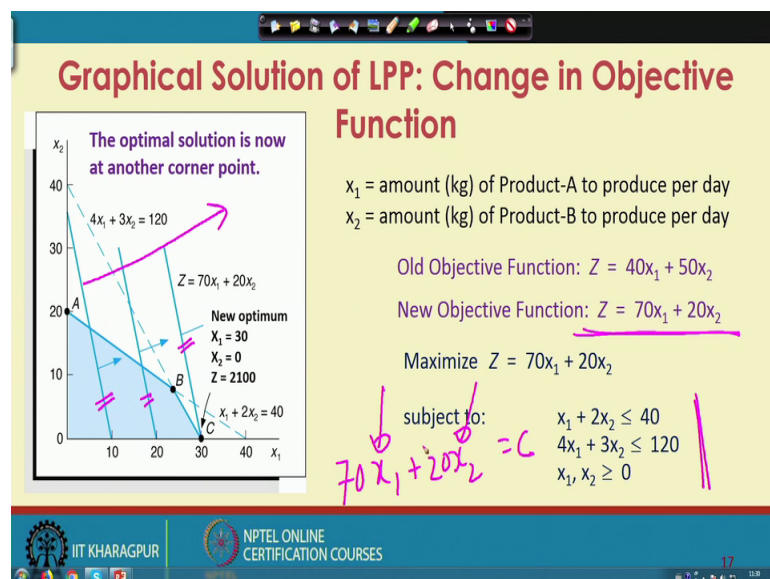

corresponding to maximum objective function value. It is if you have very few corner points, but if you have say 1000s of corner points then such visiting each and every corner point and finding all the objective function value may be very cumbersome.

Simplex method that we will talk about in the next class, in the next week are very appropriate problems are very appropriate solution techniques for such problem. There, we will see that we do not have to visit each and every corner point, but we just have to visit the minimum required number of the corner points so that you can get the optimal solution quickly. So, one thing we understand here is that the solution lies in one or more corner point.

Linear programming problem is a convex problem we have discussed that the objective function is linear all the constraints are linear. So, the problem is the convex optimization problem. All the constraints are linear, so you can note that the feasible region is also a convex region. Take any two points within this region; join them every point on this line will lie within this feasible region.

So, the constraint is a feasible region the objective function is convex, the feasible region is convex, objective function is convex, it is a convex programming problem. So, the optimal solution is actually a global optimal solution. So, the optimal solution for the linear programming problem is a global optimal solution because linear programming problem is a convex optimization problem.

(Refer Slide Time: 32:10)

What happens if I change the objective function? In case of previous problem we have the objective function Z equal to $40x_1$ plus $50x_2$. Let us now change the objective function from $40x_1$ plus $50x_2$ to Z equal to $70x_1$ plus $20x_2$. We have kept the constraints unchanged the feasible region remains unchanged.

So, now I have to plot $70x_1$ plus $20x_2$ equal to some constraint C , as objective function lines. So, this is the objective function lines, these are the objective function lines and you see again the objective function values increasing in this direction.

Now, if you look at this figure you see point C is the new optimum point C corresponds to solution x_1 equal to 30 x_2 equal to 0 and Z equal to 2100 , put x_1 equal to 30 here and x_2 equal to 0 here you get Z equal to 2100 . So, when you change the objective function without changing the constraints, I get the new optimum at another corner point. So, optimal solution is always lies within the corner point. So, with this we stop our lecture 37 here.
