Lecture - 04
Introduction to Optimization (Contd.)

Welcome to lecture 4, in this first week of Optimization in Chemical Engineering course, we are talking about introduction to optimization. So, after giving you a brief introduction to optimization and after talking about problem statement classification of optimization problems and after giving few examples on engineering applications of optimizations, in today's class and in the next class we will briefly review linear algebra that may be required for our course.

(Refer Slide Time: 00:52)

Introduction to Optimization

Week 1:

- Introduction
- Statement of optimization problems
- Classification of optimization problems
- Examples of engineering applications
- Review of linear algebra

Today's Topic:

- Review of linear algebra

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES

2

So, today we will start our review on linear algebra.

(Refer Slide Time: 01:03)

Vector

Vector is a directed line segment in N-dimensions. It has both "length" and "direction".

Vector in R^n is an ordered set of n real numbers.

$\begin{pmatrix} a \\ b \end{pmatrix}^T = (a \ b)$

– $v = (1,6,3,4)$ is in R^4

– column vector: $\begin{pmatrix} 1 \\ 6 \\ 3 \\ 4 \end{pmatrix}$

$\vec{v} = \begin{bmatrix} a \\ b \\ c \end{bmatrix}$

– row vector: $(1 \ 6 \ 3 \ 4)$

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES

3

So, dealing our discussion on linear dealing our discussion on review on linear algebra, we will essentially talk about vectors and matrices. So, today we will talk about vectors and various vector operations. Vector is the directed line segment in N dimensions it has both lengths and direction. Vector in N dimensional real space is an ordered set of n real numbers. So, an N dimensional real space is shown like this R to the power n. So, v equal to 1634 is a vector in 4 dimensional real space, why because it has 4 number of elements. The column vector is written like this whereas, row vector is written like this. You know the transpose of the column vector will be a row vector a vector is also represented like this.

(Refer Slide Time: 02:47)

Vector Addition and Vector Subtraction

$$u + v = \begin{bmatrix} u_1 \\ u_2 \end{bmatrix} + \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} u_1 + v_1 \\ u_2 + v_2 \end{bmatrix}$$
$$u - v = \begin{bmatrix} u_1 \\ u_2 \end{bmatrix} - \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} u_1 - v_1 \\ u_2 - v_2 \end{bmatrix}$$

The difference of two vectors is the result of adding a negative vector

$$A - B = A + (-B)$$

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES

See if you have a vector with elements u_1 and u_2 you have another vectors elements v_1 and v_2 , the addition of vectors will be u_1 plus v_1 as first element, and u_2 plus v_2 as second element. So, both the vectors have same number of elements. So, we can perform vector addition. Similarly vector subtraction; you will subtract elements of first vector and elements of second vector. So, u_1 minus v_1 is be the first element, u_2 minus v_2 will be the second element.

The difference of 2 vectors is the result of adding a negative vector. So, it can be written as A minus B equal to A plus minus of B .

(Refer Slide Time: 04:08)

Properties of Vector Addition

1. **Commutative:** $A+B = B+A$
2. **Associative:** $(A+B)+C = A+(B+C)$
3. There is a ZERO vector $0 = [0, 0, \dots, 0]^T$ such that $A + 0 = 0 + A = A$

Note:

1. $B + (A-B) = A$
2. $-(-B) = B$
3. $-(A-B) = B-A$

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES

Here are some properties of vector addition. Vector addition follows commutative property. So, A plus B equal to B plus A it follows Associative law.

(Refer Slide Time: 04:29)

Vector Multiplication: By Scalar

$$\alpha \mathbf{v} = \alpha(x_1, x_2) = (\alpha x_1, \alpha x_2)$$

Properties:

1. **Distributive:**
 $\alpha(A+B) = \alpha A + \alpha B$
 $(\alpha + \beta)A = \alpha A + \beta B$
2. **Associative:** $\alpha(\beta A) = (\alpha\beta)A$

The scalar 1, α , 0, -1 satisfies:

$$1A = A, \quad \alpha 0 = 0,$$
$$0\alpha = 0, \quad (-1)A = -A$$

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES

So, if you perform.

(Refer Slide Time: 04:31)

Properties of Vector Addition

1. **Commutative:** $A+B = B+A$
2. **Associative:** $(A+B)+C = A+(B+C)$
3. There is a ZERO vector $0 = [0, 0, \dots, 0]^T$ such that $A+0 = 0+A = A$

Note:

1. $B + (A-B) = A$
2. $-(B) = B$
3. $-(A-B) = B-A$

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES

A plus b first and then add C to it, the result will be same as if you perform B plus C and then add A to it. There is a zero vector for which all the elements are 0. So, if I add a zero vector to another vector a the result will be A. So, A plus 0 equal to 0 plus A equal to A. Note this properties B plus A minus B equal to A minus of minus B equal to B minus of A minus B equal to B minus A. So, vector follows these rules.

(Refer Slide Time: 05:44)

Vector Multiplication: By Scalar

$$\alpha \mathbf{v} = \alpha(x_1, x_2) = (\alpha x_1, \alpha x_2)$$

Properties:

1. **Distributive:** $\alpha(A+B) = \alpha A + \alpha B$
 $(\alpha + \beta)A = \alpha A + \beta B$
2. **Associative:** $\alpha(\beta A) = (\alpha\beta)A$

The scalar 1, α , 0, -1 satisfies:

$$1A = A, \quad \alpha 0 = 0,$$
$$0\alpha = 0, \quad (-1)A = -A$$

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES

What happens if I multiply a vector by a scalar consider v a vector which has elements let us say x 1 and x 2. You multiply the vector let say by a scalar alpha. What happens is,

each element of the vector gets multiplied by alpha. So, the direction of the vector remain same, but it magnitude changes, magnitude becomes alpha times the vector. So, it becomes scaling. So, vector multiplication by scalar follows distributive property. So, alpha into A plus B is alpha A plus alpha B, alpha plus beta into A equal to alpha A plus beta B where both alpha and beta are scalars.

Vector multiplication by scalar also follows associative rule. So, alpha into beta into A is alpha beta into A. If you take scalars 1 alpha 0 or minus 1, they will satisfy 1 into A equal to A, alpha into 0 equal to 0, 0 into alpha equal to 0 minus 1 into A equal to minus A.

(Refer Slide Time: 07:50)

Linear Combination

Given: vectors v_1, v_2, \dots, v_n in \mathbb{R}^n and n real number c_1, c_2, \dots, c_n ,
the vector x obtained by $x = c_1 v_1 + c_2 v_2 + \dots + c_n v_n$
is called a **linear combination** of v_1, v_2, \dots, v_n

Examples of linear combination of v_1 and v_2 :

$\frac{1}{2}v_1 + \sqrt{5}v_2$ $0.5v_2 = 0v_1 + 0.5v_2$

IIT KHARAGPUR NPTEL ONLINE CERTIFICATION COURSES

What do you understand by linear combination of vectors? Let us consider vectors v_1, v_2, v_3, v_4 up to v_n in n dimensional real space. And also consider n real numbers as c_1, c_2, c_3, c_4, c_5 up to c_n . So, the vector that I obtained by linear combination of v_1, v_2, v_3, v_4, v_n is called a linear combination of vectors v_1, v_2, v_3 up to v_n ; that means, the vector x obtained as c_1 into v_1 , plus c_2 into v_2 , plus c_3 into v_3 up to c_n into v_n is called a linear combination of vectors v_1, v_2, v_3 up to v_n . Examples of linear combinations of v_1 and v_2 may be $0.5 v_1$ plus say square root 5 v_2 ; $0.5 v_2$ equal to 0 into v_1 plus 0.5 into v_2 .

(Refer Slide Time: 09:33)

Linear Independence

A set of vectors $\{v_1, v_2, \dots, v_k\}$ is called **linearly dependent** if there exist scalars c_1, c_2, \dots, c_k , not all zero, such that $c_1 v_1 + c_2 v_2 + \dots + c_k v_k = 0$ (i.e. $\sum_i c_i v_i = 0$)

The vectors are **linearly independent** if the above equation is satisfied **ONLY** by $c_1 = c_2 = \dots = c_k = 0$

Examples:

The set $S = \{(1, 2), (2, 4)\}$ is linearly dependent because $-2(1, 2) + 1(2, 4) = (0, 0)$

The set $S = \{(1, 0), (0, 1), (-2, 5)\}$ is linearly dependent because $2(1, 0) - 5(0, 1) + 1(-2, 5) = (0, 0)$

Handwritten calculation for the second example:
 $-2 \begin{bmatrix} 1 \\ 2 \end{bmatrix} + 1 \begin{bmatrix} 2 \\ 4 \end{bmatrix} = \begin{bmatrix} -2+2 \\ -4+4 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES

Linear independence of vectors; this is important. We need to understand what you mean by linearly independent vectors. A set of vectors v_1, v_2 up to v_k is called linearly dependent if there exist scalars c_1, c_2 up to c_k not all 0 such that, $c_1 v_1$ plus $c_2 v_2$ up to $c_k v_k$ equal to 0. So, if you have vectors v_1, v_2 up to v_k , and there exist scalars c_1, c_2 up to c_k which are not all zeroes then if $c_i v_i$ equal to 0 meaning $c_1 v_1$ plus $c_2 v_2$ up to $c_k v_k$ equal to 0, then the set of vectors v_1, v_2 up to v_k is called linearly dependent.

The vectors v_1, v_2 up to v_k will be linearly independent if $\sum c_i v_i$ equal to 0 or $c_1 v_1$ plus $c_2 v_2$ up to $c_k v_k$ equal to 0, only when c_1, c_2 all c_k equal to 0. So, for vectors that are linearly independent $\sum c_i v_i$ equal to 0 only when c_1, c_2 up to c_k equal to 0. So, here are some examples of linearly dependent vectors, consider I have a set of vector 1 2 and 3 4. So, you have 1 2 you have 3 4.

The question is these vectors linearly dependent or independent. They are linearly dependent because if we do this; that means, if I consider c_1 as minus 2 and c_2 as 1 and take the sum $c_1 v_1$ plus $c_2 v_2$, I get 0 why. So, this is minus 2 this is 2 4; so minus 2 plus 2 minus 4 plus 4 equal to 0 0.

(Refer Slide Time: 13:36)

Linear Independence

A set of vectors $\{v_1, v_2, \dots, v_k\}$ is called **linearly dependent** if there exist scalars c_1, c_2, \dots, c_k , not all zero, such that $c_1v_1 + c_2v_2 + \dots + c_kv_k = 0$ (i.e. $\sum_i c_i v_i = 0$)

The vectors are **linearly independent** if the above equation is satisfied **ONLY** by $c_1 = c_2 = \dots = c_k = 0$

Examples:

The set $S = \{(1, 2), (3, 4)\}$ is linearly dependent because $-2(1, 2) + 1(2, 4) = (0, 0)$

The set $S = \{(1, 0), (0, 1), (-2, 5)\}$ is linearly dependent because $2(1, 0) - 5(0, 1) + 1(-2, 5) = (0, 0)$

Handwritten calculations on the slide:

$$2 \begin{bmatrix} 1 \\ 0 \end{bmatrix} + 5 \begin{bmatrix} 0 \\ 1 \end{bmatrix} + 1 \begin{bmatrix} -2 \\ 5 \end{bmatrix} = \begin{bmatrix} 2 - 0 - 2 \\ 0 - 5 + 5 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES

Similarly, the vectors $1 \ 0 \ 0 \ 1$ minus $2 \ 5$ is also linearly dependent, because you can also show that $2 \ 1 \ 0$ plus its minus $5 \ 0 \ 1$ plus 1 minus $2 \ 5$ equal to 2 minus 2 minus 0 minus 2 0 minus 5 plus 5 equal to $0 \ 0$. So, this set of vectors are also linearly dependent.

(Refer Slide Time: 14:26)

Linear Independence

Determine whether the following set of vectors is linearly dependent or linearly Independent: $v_1 = (1, 2, 3)$, $v_2 = (0, 1, 2)$, $v_3 = (-2, 0, 1)$

Solution: $c_1v_1 + c_2v_2 + c_3v_3 = 0$
 $\Rightarrow c_1(1, 2, 3) + c_2(0, 1, 2) + c_3(-2, 0, 1) = (0, 0, 0)$

Handwritten calculations on the slide:

$$c_1 \begin{bmatrix} 1 \\ 2 \\ 3 \end{bmatrix} + c_2 \begin{bmatrix} 0 \\ 1 \\ 2 \end{bmatrix} + c_3 \begin{bmatrix} -2 \\ 0 \\ 1 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}$$

$$\begin{cases} c_1 - 2c_3 = 0 \\ 2c_1 + c_2 = 0 \\ 3c_1 + 2c_2 + c_3 = 0 \end{cases} = \begin{bmatrix} c_1 - 2c_3 \\ 2c_1 + c_2 \\ 3c_1 + 2c_2 + c_3 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}$$

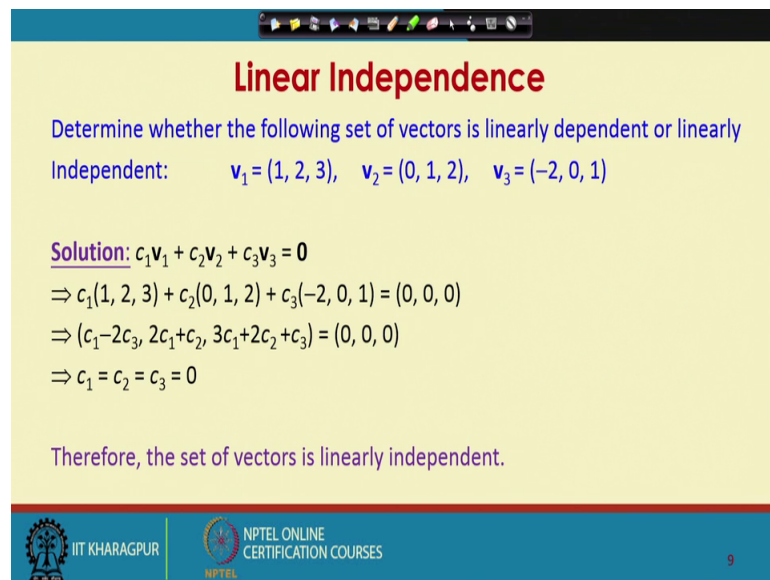

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES

Now, let us consider another example. We have the following set of vectors v_1 equal to $1 \ 2 \ 3$, v_2 equal to $0 \ 1 \ 2$ and v_3 equal to $-2 \ 0 \ 1$ are these vectors linearly dependent or linearly independent let us follow the same procedure. If the set of vectors has a

linearly independent so, the sum $c_1 v_1 + c_2 v_2 + c_3 v_3$ will be equal to 0, only when $c_1 = 0$, $c_2 = 0$ and $c_3 = 0$.

So, let us get the sum $C_1 \begin{pmatrix} 1 \\ 2 \\ 3 \end{pmatrix} + C_2 \begin{pmatrix} 0 \\ 1 \\ 2 \end{pmatrix} + C_3 \begin{pmatrix} -2 \\ 0 \\ 1 \end{pmatrix} = \begin{pmatrix} 0 \\ 0 \\ 0 \end{pmatrix}$. So, this will be equal to 0. So, do the sum which will be $C_1 + 0 - 2C_3$, $2C_1 + C_2$ plus 0, $3C_1 + 2C_2 + C_3$ equal to 0, 0 and 0. So, this is also 0, 0 and 0. So, basically you have 3 equations $C_1 - 2C_3 = 0$, $2C_1 + C_2 = 0$, $3C_1 + 2C_2 + C_3 = 0$. So, you have 3 equations in C_1 , C_2 and C_3 you can solve this 3 equations and find the values of C_1 , C_2 and C_3 . You will see that the values are coming as $C_1 = 0$, $C_2 = 0$ and $C_3 = 0$; that means, this set of vectors are linearly independent.

(Refer Slide Time: 17:03)

Linear Independence

Determine whether the following set of vectors is linearly dependent or linearly Independent: $v_1 = (1, 2, 3)$, $v_2 = (0, 1, 2)$, $v_3 = (-2, 0, 1)$

Solution: $c_1 v_1 + c_2 v_2 + c_3 v_3 = \mathbf{0}$

$$\Rightarrow c_1(1, 2, 3) + c_2(0, 1, 2) + c_3(-2, 0, 1) = (0, 0, 0)$$
$$\Rightarrow (c_1 - 2c_3, 2c_1 + c_2, 3c_1 + 2c_2 + c_3) = (0, 0, 0)$$
$$\Rightarrow c_1 = c_2 = c_3 = 0$$

Therefore, the set of vectors is linearly independent.

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES

9

So, that is why you can see here.

(Refer Slide Time: 17:09)

Linear Independence: Properties

- A set of vectors is linearly dependent if and only if one of the vectors is a linear combination of the others.
- Any set of vectors containing the zero vector is linearly dependent.
- If a set of vectors is linearly independent, then any subset of these vectors is also linearly independent.
- If a set of vectors is linearly dependent, then any larger set, containing this set, is also linearly dependent.

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES

A set of vectors is linearly dependent if and only if one of the vectors is a linear combination of the others. So, we are talking about some properties of linear independence. A set of vectors is linearly dependent if and only if 1 of the vectors is a linear combination of the others.

Any set of vectors containing the zero vector is linearly dependent. So, any set of vectors containing the zero vector is linearly dependent. If a set of vectors is linearly independent then any subset of these vectors is also linearly independent. So, if a set of vectors is linearly independent, then any subset of these vectors is also linearly independent if a set of if a set of vectors is linearly dependent then any larger set containing this set is also linearly dependent I repeat if a set of vectors is linearly dependent then any larger set containing this set is also linearly dependent.

(Refer Slide Time: 18:27)

Dot Product (Inner Product, Scalar Product) of Vectors

$A \cdot B = A^T B = [a \ b \ c] \begin{bmatrix} d \\ e \\ f \end{bmatrix} = ad + be + cf$

$\|A\|^2 = A^T A = aa + bb + cc$

$A \cdot B = \|A\| \|B\| \cos(\theta)$

The dot product is a scalar

$\langle x, y \rangle = \sum_{i=1}^n x_i y_i$

The magnitude of a vector is the dot product of a vector with itself

The dot product is related to the angle between the two vectors

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES

Now, let us talk about dot product of vectors. The dot product of vectors are also known as inner product or scalar product. You can consider this dot product as something similar to matrix multiplication. So, the dot product between 2 vectors A and B, which is also represented as A transpose B is the product like this. So, a b c a and b are both column vectors you have taken A transpose B. So, A becomes row vector and B becomes column vector.

So, if I say if tells of matrix notation this is 1 row 3 column, this is 3 rows 1 column. So, the multiplication is defined because column of the first matrix a is equal to rows of second matrix b you also can immediately see then the product will have dimension 1 by one; that means, is going to be a scalar. So, the dot product is a scalar quantity. So, if the elements of matrix a is a b c and the elements of matrix b are d e f. So, the dot product between a and b is, a d plus b e plus c f which is a scalar quantity. So, the dot product is also represented like this 2 vectors x and y, the dot product is sigma x i y i for all values of i equal to 1 to n where n at the number of components in vectors x and y.

The magnitude of a vector is that dot product of a vector with itself. So, A transpose A if a has elements a b and c, A transpose A becomes a a plus b b plus c c this becomes the magnitude of the vector a. The dot product is related to the angle between the 2 vectors. So, 2 vectors A and B, the dot product between 2 vectors A and B can be written as a to b into cos theta where theta is the angle between these 2 vectors a and b.

(Refer Slide Time: 21:40)

Inner Product Vs Outer Product

Inner product: $u \cdot v = u^T v = (u_1 \ u_2) \begin{pmatrix} v_1 \\ v_2 \end{pmatrix} = u_1 v_1 + u_2 v_2$

Outer product: $u v^T = \begin{pmatrix} u_1 \\ u_2 \end{pmatrix} \begin{pmatrix} v_1 & v_2 \end{pmatrix} = \begin{pmatrix} u_1 v_1 & u_1 v_2 \\ u_2 v_1 & u_2 v_2 \end{pmatrix}$

Handwritten notes: 2x1 1x2 = 2x2

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES

Corresponding to inner product, we have also another term called outer product. So, the inner product or the dot product between u and v let us say I have 2 vectors u and v and the elements of u vector is u_1 and u_2 , and the elements of v vector is v_1 and v_2 . So, the inner product or the dot product between u and v is $u \cdot v$ equal to $u^T v$ is $u_1 v_1 + u_2 v_2$.

But the outer product is outer product between u and v is, $u v^T$ or $v u^T$. So, inner product is $u^T v$ outer product is $u v^T$. So, u and v are both column vectors. So, u is column vectors now v^T that becomes a row vector. So, u_1, u_2, v_1, v_2 ; v_1, v_2 is the column vector. So, you have 2 rows 1 column; v_1, v_2 now has become row vector after taking transpose and it has 1 row 2 column. So, the matrix multiplication is defined and the product is going to be 2 by 2 matrix. So, this is what you get $u_1 v_1, u_1 v_2$ elements of first row, $u_2 v_1, u_2 v_2$ are the elements of second row.

(Refer Slide Time: 23:41)

Vector Norms

The norm of a vector is a measure of the magnitude or length of the vector.

$\|x\|_1 = \sum_{i=1}^n |x_i|$
1-norm

$\|x\|_2 = \left(\sum_{i=1}^n |x_i|^2 \right)^{1/2}$
2-norm

$\|x\|_\infty = \max_i |x_i|$
 ∞ -norm

In general, p-norm: $\|x\|_p = \left(\sum_{i=1}^n |x_i|^p \right)^{1/p}$

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES

Vector norms: the norm of a vector is a measure of the magnitude or length of the vector. There are different types of norms common norms are 1 norm, 2 norm or infinity norm. 1 norm is defined as this. So, you sum up the absolute values of all the elements in the vector, 2 norm is defined like this. You square all the elements in the vector sum them up and take the square root. Infinity norms is defined as this where you take the maximum value of the elements in the vector. So, in general the p norm is defined as this. Look at the similarity between the 2 norm and the p norm. So, put p equal to 2 it becomes 2 norms. So, mod x to the power p sum them up and then rest to the power 1 by p.

(Refer Slide Time: 25:50)

Vector Norms: Properties

$\|x\| > 0$ if $x \neq 0$

$\|\alpha x\| = |\alpha| \cdot \|x\|$ for any scalar α

$\|x + y\| \leq \|x\| + \|y\|$ (triangle inequality)

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES

Here are some properties of vector norms. The norm of a vector is greater than 0 if x is not equal to 0. So, if x is not equal to 0 the norm of a vector which represents the length of magnitude of the vector is always greater than 0. Consider vector x consider a scalar α . So, the norm of αx is equal to absolute value of α into norm of x .

And finally, norm of sum of 2 vectors is less than sum of norm of those 2 vectors this is known as triangle inequality. So, if you consider vector x , if you consider vector y you sum the vector x plus y , take the norm of x plus y that will be less or equal to sum of norm of x plus norm of y . So, that is known as norm of triangle inequality.

With this we stop our lecture 4 here.
