**Lecture - 40**  
**Introduction to Linear Programming (Contd.)**

Welcome to lecture 40; this is week 8 and we have been talking about Introduction to Linear Programming problems. So, in this week we have introduced linear programming problems then, we have discussed about graphical method of solutions; which is essentially convenient only for two variable problems. In this lecture, we will talk about more on standard form of linear programming problems that we have discussed in your previous lecture. So, we will introduce certain definitions related to the standard form of linear programming problem.

And then we will discuss about solutions of set of linear equations say using Gauss Jordan elimination method that will lead to the canonical form of the systems of linear equations. These discussions, will lay the foundation for our discussion on simplex method that we will cover in the next week.

(Refer Slide Time: 01:49)

**Linear Program in Standard Form: Some Definitions**

Maximize:  $Z = c^T x$   
Subject to  $Ax = b$   
 $x \geq 0, b \geq 0$

A:  $m \times n$  matrix  
 $x$ :  $n \times 1$  vector  
 $b$ :  $m \times 1$  vector  
 $c$ :  $n \times 1$  vector

A feasible solution is a nonnegative vector  $x$  that satisfy the constraints:  $Ax = b$

A feasible region, denoted by  $S$ , is the set of all feasible solutions. Mathematically, we can write:  $S = \{x | Ax = b, x \geq 0\}$

If the feasible set  $S$  is empty, then the linear program is infeasible.

An optimal solution is a vector  $x^*$  that is feasible and its value of the objective function ( $cx^*$ ) is greater than any other feasible solution. Mathematically,  $cx^* \geq cx \forall x \in S$

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES

So, in matrix notation we have presented a linear programming problem in standard form as maximize or minimize  $Z$  equal to  $c$  transpose  $x$  subject to  $x$  equal to  $b$   $x$  greater or

equal to 0  $b \geq 0$ .  $A$  is  $m$  by  $n$  matrix,  $x$  is  $n$  vector,  $c$  is  $n$  vector and  $b$  is  $m$  vector.

Now we will introduce some definitions some of them you are already familiar with so, we will review some of those definitions you are already familiar with. A feasible solution is the non negative vector  $x$  that satisfies the constraints  $Ax = b$ .

So, these notations are related to the problem formulation maximize  $Z = c^T x$  subject to  $Ax = b$ ;  $x \geq 0$ ,  $b \geq 0$ . A feasible solution is a non negative vector  $x$  that satisfy the constraints  $Ax = b$ , A feasible region denoted by  $S$  is the set of all feasible solutions.

So, mathematically we can write  $S = \{x \text{ such that } Ax = b; x \geq 0\}$ . If the feasible set  $S$  is empty, then the linear program is infeasible. An optimal solution is a vector  $x^*$  that is feasible and its value of the objective function  $c^T x^*$  is greater than any other feasible solution. So, if  $x^*$  is optimal solution; it will be feasible and the objective function value at  $x^*$  that is  $c^T x^*$  will be greater or equal to  $c^T x$  for all  $x$  belonging to the feasible region  $S$ .

(Refer Slide Time: 04:24)

**Linear Program in Standard Form: Some Definitions**

Maximize:  $Z = c^T x$   
Subject to  $Ax = b$   
 $x \geq 0, b \geq 0$

The optimal value of a LP is the value of the objective function at the optimal solution. Thus, if  $x^*$  is the optimal solution, then  $Z^* = c^T x^*$  is the optimal value of the LP.

$A$ :  $m \times n$  matrix  
 $x$ :  $n \times 1$  vector  
 $b$ :  $m \times 1$  vector  
 $c$ :  $n \times 1$  vector

If a LP has more than one optimal solution, it is said to have alternate optimal solutions. In this case there will exist more than one feasible solutions having the same optimal value  $Z^*$  of the objective function.

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES | NPTEL

4

The optimal value of a linear program is the value of the objective function at the optimal solution. Thus, if  $x^*$  is the optimal solution then  $Z^* = c^T x^*$  is the optimal value of the linear program.

If a linear program has more than one optimal solution it is said to have alternate optimal solutions. In this case, there will exist more than one feasible solutions having the same optimal value  $Z^*$  of the objective function.

(Refer Slide Time: 05:05)

**Linear Program in Standard Form: Some Definitions**

Maximize:  $Z = c^T x$   
Subject to  $Ax = b$   
 $x \geq 0, b \geq 0$

The optimal solution of a LP is said to be unique when there exists no other optimal solution.

When a LP does not have a finite optimum, it is said to have unbounded optimum. Then,

A:  $m \times n$  matrix  
x:  $n \times 1$  vector  
b:  $m \times 1$  vector  
c:  $n \times 1$  vector

$\max Z \rightarrow +\infty$   
or  
 $\min Z \rightarrow -\infty$

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES

The optimal solution of a LP or Linear Program is said to be unique when there exists no other optimal solution. So, there is only one optimal solution, when a linear program does not have a finite optimum, it is said to have unbounded optimum.

Then maximization of  $Z$  will lead to plus infinity minimization of  $Z$  will lead to minus infinity. You can go on increasing or decreasing the objective function without any bound depending on whether you have solving a maximization problem or minimization problem.

(Refer Slide Time: 06:02)

**Solving System of Linear Equations: Square System**

$$\begin{aligned} a_{11}x_1 + a_{12}x_2 + \dots + a_{1n}x_n &= b_1 & (E_1) \\ a_{21}x_1 + a_{22}x_2 + \dots + a_{2n}x_n &= b_2 & (E_2) \\ a_{31}x_1 + a_{32}x_2 + \dots + a_{3n}x_n &= b_3 & (E_3) \\ \vdots & & \\ a_{n1}x_1 + a_{n2}x_2 + \dots + a_{nn}x_n &= b_n & (E_n) \end{aligned}$$

Consider the system of  $n$  equations with  $n$  variables.

$E_3 = E_3 + 2E_2$

The above system of equations will not be altered under the following elementary operations:

- Any equation  $E_r$  is replaced by the equation  $kE_r$ , where  $k$  is a nonzero constant
- Any equation  $E_r$  is replaced by the equation  $E_r + kE_s$ , where  $E_s$  is any other equation of the system

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES

Now, let us discuss the solution of system of linear equations. First let us consider a square system, by square system; I mean I have a system of  $n$  equations with  $n$  variables. So, there are  $n$  variables and then  $n$  equations.

So, the system can be solved uniquely, the system can be easily solved because you have  $n$  variables and  $n$  equations. So, the equations are presented as a  $1 \times 1$  plus a  $1 \times 2$  up to a  $1 \times n$  equal to  $b_1$  and so on and so forth; a  $2 \times 1$  plus a  $2 \times 2$  plus a  $2 \times n$ ;  $x_1$  equal to  $b_2$ .

It is a square system; so, there are  $n$  variables and  $n$  equations. So, you will have  $n$  rows of equations and there will be  $n$  columns of these variables. This system of equations will not be altered under a certain set of elementary operations. There exists a set of elementary operations, which when we apply on this set of linear equations; the system will not be altered; that means, the solutions of the transformed set of equations and the solutions of the original equations will be same. So, let us discuss these 2 elementary operations.

Any equation  $E_r$  is replaced by the equation  $kE_r$ , where  $k$  is a nonzero constant. So, pick up any equation; let us say I have picked up the second equation, if I replace this equation by multiplying this equation by a nonzero constant, the system of equations will not be changed.

So, this is one elementary operations that you can replace a row by a multiple of that row. Second elementary operation any equation  $E_r$  is replaced by the equation  $E_r$  plus  $k$  into  $E_s$  where  $k$  is a nonzero constant and  $E_s$  is any other equation of the system. So, this tells you that I can replace this equation number 3 or 3rd row by sum of third row and let us say a multiplication of the second row or any other row. So, the third equation or the 3rd row can be replaced as sum of 3rd row; plus let us say 2 into 2nd row, if I do this the transformed set of equations and the original set of equations we will have same solutions.

And that is what we mean when I say the system of equations will not be altered. So, these two elementary operations can be performed on the set of linear equations without altering the solutions. So, first one is any equation can be replaced by a multiple of that equation. .

You have to multiply that equation by any nonzero constant and can the equation can be replaced by a multiple of that equation. Second elementary operation is any equation can be replaced by a sum of that equation and a multiple of any other equation.

(Refer Slide Time: 11:52)

**Solving System of Linear Equations: Canonical Form**

$a_{11}x_1 + a_{12}x_2 + \dots + a_{1n}x_n = b_1$  ( $E_1$ )  
 $a_{21}x_1 + a_{22}x_2 + \dots + a_{2n}x_n = b_2$  ( $E_2$ )  
 $a_{31}x_1 + a_{32}x_2 + \dots + a_{3n}x_n = b_3$  ( $E_3$ )  
 $\vdots$   
 $a_{n1}x_1 + a_{n2}x_2 + \dots + a_{nn}x_n = b_n$  ( $E_n$ )

Operation at each step to eliminate one variable at a time, from all equations except one, is known as **pivotal operation**. Number of **pivotal operations** are same as the number of variables in the set of equations.

$1x_1 + 0x_2 + 0x_3 + \dots + 0x_n = b_1$   
 $0x_1 + 1x_2 + 0x_3 + \dots + 0x_n = b_2$   
 $0x_1 + 0x_2 + 1x_3 + \dots + 0x_n = b_3$   
 $\vdots$   
 $0x_1 + 0x_2 + 0x_3 + \dots + 1x_n = b_n$

Canonical form may be obtained after  $n$  pivotal operations

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES

So, when I have this set of linear equations and I perform those two elementary operations; it is possible for me to express this set of equation in a form known as canonical form.

And if you closely look at in this canonical form; the first row; that means, the first equations has coefficient 1 for variable  $x_1$  that is first column and all other coefficients are 0. Right hand side  $b_1$  has now been depressed as  $b_1'$  because those elementary row operations has been performed.

So, essentially the first equation is  $x_1$  equal to  $b_1'$ . Similarly in the canonical form the second row has been transformed to a row where only  $x_2$  has coefficient equal to 1 all other variables has coefficient 0.

So, essentially making this equation as  $x_2$  equal to  $b_2'$ , this continues and the last row that is  $n$ th row because, you now have  $n \times n$  matrix ; the  $n$ th row has all the coefficients 0 coefficients for  $x_1, x_2$  up to  $x_{n-1}$  and the coefficient of  $x_n$  is 1.

So, this equation is essentially  $x_n$  equal to  $b_n'$ . So, it is possible to transform the original set of linear equations to a canonical form as shown. Operation at each step to eliminate one variable at a time from all equations except one is known as pivotal operation.

Note that in the canonical form each row has only one variable because, all other has been reduced to 0. In the canonical form if you pick up any row only one variable has coefficient 1; all other variables has coefficient 0. Operation at each step to eliminate one variable at a time from all equations except 1 is known as pivotal operation number of pivotal operations are same as the number of variables in the set of equations. So, the system of  $n$  equations in  $n$  variables were converted to canonical form after  $n$  pivotal operations.

(Refer Slide Time: 15:58)

**Solving System of Linear Equations: Canonical Form**

$a_{11}x_1 + a_{12}x_2 + \dots + a_{1n}x_n = b_1$  (E<sub>1</sub>)  
 $a_{21}x_1 + a_{22}x_2 + \dots + a_{2n}x_n = b_2$  (E<sub>2</sub>)  
 $a_{31}x_1 + a_{32}x_2 + \dots + a_{3n}x_n = b_3$  (E<sub>3</sub>)  
 $\vdots$   
 $a_{m1}x_1 + a_{m2}x_2 + \dots + a_{mn}x_n = b_n$  (E<sub>n</sub>)

→

**Canonical form**

$1x_1 + 0x_2 + 0x_3 + \dots + 0x_n = b_1''$   
 $0x_1 + 1x_2 + 0x_3 + \dots + 0x_n = b_2''$   
 $0x_1 + 0x_2 + 1x_3 + \dots + 0x_n = b_3''$   
 $\vdots$   
 $0x_1 + 0x_2 + 0x_3 + \dots + 1x_n = b_n''$

Transformed set of equations through elementary operations is equivalent to the original set of equations. Thus, solution of transformed set of equations is the solution of original set of equations.

The solution may be easily obtained from canonical form as:  $x_i = b_i''$ ,  $i = 1, 2, \dots, n$

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES

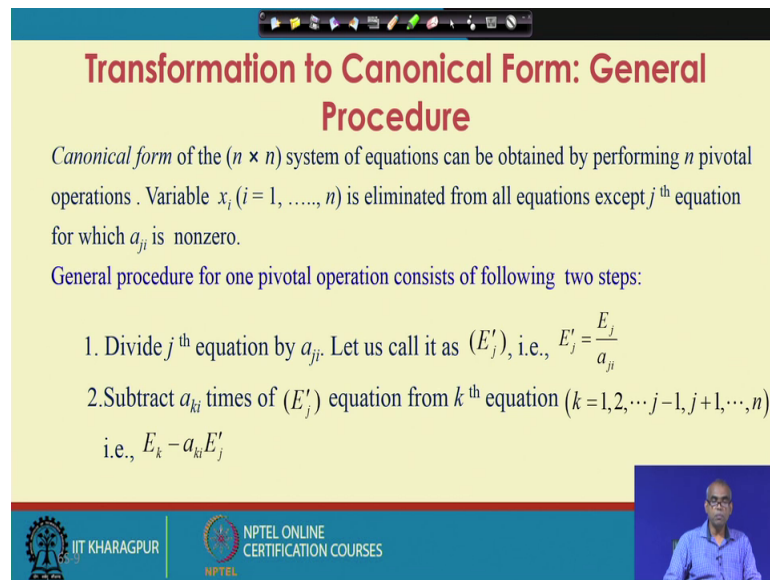

Transform set of equations through elementary operations is equivalent to the original set of equations. We discussed that these elementary operations do not alter the set of equations. In fact, they do not alter the solutions of the original equations.

Because, the transform set of equations that we obtain through elementary operations is equivalent to the original set of equations. Thus the solution of transform set of equation is the solution of the original set of equation.

Now, if you look at the canonical form the solutions are readily obtained from the 1st row; we obtain the solution as  $x_1$  equal to  $b_1''$ ; from the 2nd row we obtain the solution as  $x_2$  equal to  $b_2''$ , from the 3rd row we obtain it as  $x_3$  equal to  $b_3''$ . Similarly from the  $n$ th row we obtain the solution as  $x_n$  equal to  $b_n''$ .

So, the solution can be easily obtained as  $x_i$  equal to  $b_i''$  for all values of  $i$  equal to 1 to  $n$ . So, once you can convert the solution sorry; if once you can convert the system of linear equations into its canonical form, you can obtain the solution very easily.

(Refer Slide Time: 17:30)

**Transformation to Canonical Form: General Procedure**

Canonical form of the  $(n \times n)$  system of equations can be obtained by performing  $n$  pivotal operations. Variable  $x_i$  ( $i = 1, \dots, n$ ) is eliminated from all equations except  $j^{\text{th}}$  equation for which  $a_{ji}$  is nonzero.

General procedure for one pivotal operation consists of following two steps:

1. Divide  $j^{\text{th}}$  equation by  $a_{jj}$ . Let us call it as  $(E'_j)$ , i.e.,  $E'_j = \frac{E_j}{a_{jj}}$
2. Subtract  $a_{ki}$  times of  $(E'_j)$  equation from  $k^{\text{th}}$  equation ( $k = 1, 2, \dots, j-1, j+1, \dots, n$ )  
i.e.,  $E_k - a_{ki}E'_j$

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES

So, here is the general procedure for transformation of the set of equations to canonical form. Canonical form of the  $n$  by  $n$  system of equations can be obtained by performing  $n$  pivotal operations; variable  $x_i$ ,  $i$  equal to 1 to  $n$  is eliminated from all equations except  $j^{\text{th}}$  equation for which  $a_{ji}$  is nonzero.

So, variable  $x_i$  is eliminated from all equations except  $j^{\text{th}}$  equation and for  $j^{\text{th}}$  equation the coefficient  $a_{ji}$  is nonzero. So, general procedure for one pivotal operation consists of the following 2 steps. First divide  $j^{\text{th}}$  equation by  $a_{jj}$ ; let us call it as  $E_j$  prime.

So,  $E_j$  prime equal to  $E_j$  by  $a_{jj}$ ; now subtract  $a_{ki}$  times of  $E_j$  prime equation from  $k^{\text{th}}$  equation; that is  $E_k$  minus  $a_{ki} E_j$  prime. So, by this you can convert the system of linear equations to its canonical form; that was about square system.

(Refer Slide Time: 19:07)

**Solving System of Linear Equations: Non-square System**

Instead of a square system, let us consider a system of  $m$  equations in  $n$  variables with  $n \geq m$ . This system of equations is assumed to be consistent so that it will have at least one solution

$$\begin{aligned} a_{11}x_1 + a_{12}x_2 + \dots + a_{1n}x_n &= b_1 \\ a_{21}x_1 + a_{22}x_2 + \dots + a_{2n}x_n &= b_2 \\ &\vdots \\ a_{m1}x_1 + a_{m2}x_2 + \dots + a_{mn}x_n &= b_m \end{aligned}$$

The solution vector  $X$  that satisfy the above equation can not be readily obtained from the equations. However, it is possible to reduce this system to an equivalent canonical system from which at least one solution can readily be deduced.

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES

What about non square system where you have  $m$  equations in  $n$  variables and  $n$  is greater than  $m$ . So, instead of square system let us consider a system of  $n$  equations in  $n$  variables with let us say  $n$  greater than  $m$ . This system of equations is assumed to be consistent so that it will have at least one solution. So, now I have this set of linear equations note that we have now  $m$  rows, and we have now  $n$  variables.

So, if we look at the coefficient matrix, it will have  $m$  rows  $n$  columns. The solution vector  $x$  that satisfy the above equation cannot be readily obtained from the equations; however, it is possible to reduce the system to an equivalent canonical system from which at least one solution can readily be obtained. Now we are talking about a situation where you have  $n$  variables and  $m$  equations and let us consider  $n$  is greater than  $m$ . So, now, let us see how we obtain the canonical form for such systems so, that one solution can be obtained.

(Refer Slide Time: 21:15)

**Solving System of Linear Equations**

Use the Gauss-Jordan elimination procedure to solve this series of linear equations.

$$\begin{aligned} x_1 + x_2 + 3x_3 + x_4 &= 7 \\ x_1 - 2x_2 + x_3 - x_5 &= 2 \end{aligned}$$

**Solution:**

**Multiply row 1 by 2 and add to row 2.**

$$\begin{aligned} x_1 + x_2 + 3x_3 + x_4 &= 7 \\ 3x_1 + 7x_3 + 2x_4 - x_5 &= 16 \end{aligned}$$

**Divide row 2 by 3.**

$$\begin{aligned} x_1 + x_2 + 3x_3 + x_4 &= 7 \\ x_1 + \frac{7}{3}x_3 + \frac{2}{3}x_4 - \frac{1}{3}x_5 &= \frac{16}{3} \end{aligned}$$

**Multiply row 2 by -1 and add to row 1.**

$$\begin{aligned} x_2 + \frac{2}{3}x_3 + \frac{1}{3}x_4 + \frac{1}{3}x_5 &= \frac{5}{3} \\ x_1 + \frac{7}{3}x_3 + \frac{2}{3}x_4 - \frac{1}{3}x_5 &= \frac{16}{3} \end{aligned}$$

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES

So, let us consider an example;  $x_1 + x_2 + 3x_3 + x_4 = 7$  and  $x_1 - 2x_2 + x_3 - x_5 = 2$ . So, I have 2 equations a number of variables is 5  $x_1 + x_2 + 3x_3 + x_4$  and  $x_5$ ; so, 5 variables 2 equations. So, let us convert this system of equation to its canonical form; first we multiply row 1 by 2 and add to row 2, if we do that you obtain this.

Next we divide row 2 by 3; you obtain this and then multiply row 2 by minus 1 and add to row 1. Now look at the system of equations that we obtained, if you look at this equation you have  $x_1$  then 0 into  $x_2$  no  $x_2$ . So,  $x_1$  into  $x_1$  plus 0 into  $x_2$  and then you have  $x_3 + x_4 + x_5$  and it has coefficients then that is equal to 16 by 3.

If you look at this equation it is 0 into  $x_1$  plus 1 into  $x_2$  then plus  $x_3 + x_4 + x_5$  you have along with its coefficients and it is a sinusoid equal to 5 by 3. So, this equation these 2 set of equations; if you look at only  $x_1$  and  $x_2$  they are in the canonical form.

(Refer Slide Time: 24:09)

**Solving System of Linear Equations**

$$x_2 + \frac{2}{3}x_3 + \frac{1}{3}x_4 + \frac{1}{3}x_5 = \frac{5}{3}$$
$$x_1 + \frac{7}{3}x_3 + \frac{2}{3}x_4 - \frac{1}{3}x_5 = \frac{16}{3}$$

**Solution:**

Set  $x_3 = 0, x_4 = 0, x_5 = 0$ :

$$x_1 = \frac{16}{3}, x_2 = \frac{5}{3}, x_3 = 0, x_4 = 0, x_5 = 0$$

$x_1$  and  $x_2$  are **basic** variables;  $x_3, x_4$  and  $x_5$  are **non-basic** variables.

The solution,  $x_1 = \frac{16}{3}, x_2 = \frac{5}{3}, x_3 = 0, x_4 = 0, x_5 = 0$  is referred to as a **basic solution** since all non-basic variables have been set to 0.

This solution is also referred to as a **basic feasible solution** since all basic variables are non-negative.

Every corner point of the feasible region corresponds to a **Basic Feasible Solution**. This is the fundamental building block for the *simplex* method.

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES | 12

So, if I said  $x_3$  equal to 0  $x_4$  equal to 0 and  $x_5$  equal to 0, I can obtain the solution as  $x_1$  equal to  $\frac{16}{3}$   $x_2$  equal to  $\frac{5}{3}$ , note that you have 2 equations and 5 variables. So, setting arbitrarily any 3 variables to 0; I can solve for the remaining 2. So, by setting  $x_3$  equal to 0  $x_4$  equal to 0 and  $x_5$  equal to 0 ; I obtain  $x_1$  equal to  $\frac{16}{3}$ ,  $x_2$  equal to  $\frac{5}{3}$  readily .

So, this is the equivalent canonical form that we discussed for square system  $n$  by  $n$ . We have a non square systems and for this  $x_1$  and  $x_2$  part here, I have that canonical form. So, the solution is  $x_1$  equal to  $\frac{16}{3}$   $x_2$  equal to  $\frac{5}{3}$ ,  $x_3$  equal to 0  $x_4$  equal to 0  $x_5$  equal to 0 ; so, this is one solution;  $x_1$  and  $x_2$  are basic variables;  $x_3, x_4$  and  $x_5$  are non basic variables.

So, the variables whose values we arbitrarily set to 0 are non basic variables, here  $x_3, x_4, x_5$  are non basic variables and  $x_1$  and  $x_2$  are basic variables. The solution that we have obtained by setting non basic variables to 0; that is  $x_1$  equal to  $\frac{16}{3}$   $x_2$  equal to  $\frac{5}{3}$   $x_3$  equal to 0  $x_4$  equal to 0  $x_5$  equal to 0 is referred to as basic solution since, all non basic variables have been set to 0.

This solution is also referred to as the basic feasible solution since all basic variables are non negative. If you look at the basic solution the solution has all basic variables as non negative. So, this solution is also referred to as basic feasible solution.

Every corner point of the basic of the every corner point of the feasible region corresponds to a basic feasible solution; this is the fundamental building block for the simplex method. Every corner point for the feasible region corresponds to a basic feasible region and this is the fundamental building block for the simplex method.

(Refer Slide Time: 27:14)

**Transformation to Canonical Form: General Case**

Maximize:  $Z = c_1x_1 + c_2x_2 + c_3x_3 + \dots + c_nx_n$

Subject to  $a_{11}x_1 + a_{12}x_2 + \dots + a_{1n}x_n = b_1$   
 $a_{21}x_1 + a_{22}x_2 + \dots + a_{2n}x_n = b_2$   
 $\dots$   
 $a_{m1}x_1 + a_{m2}x_2 + \dots + a_{mn}x_n = b_m$   
 $x_1 \geq 0, x_2 \geq 0, \dots, x_n \geq 0$   
 $b_1 \geq 0, b_2 \geq 0, \dots, b_m \geq 0$

In general,  $m < n$  which leads to infinite number of feasible solutions. Hence selection of best feasible solution which maximizes  $Z$  is not an easy problem.

To generate the solutions, use first  $m$  variables ( $x_1, \dots, x_m$ ), reduce the system to canonical or row echelon form by Gauss-Jordan elimination.

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES | 13

Now, let us transform a set of equations to a canonical form in a more general case. So, we have the objective function  $Z$  equal to  $c_1x_1 + c_2x_2 + \dots + c_nx_n$ . And we have  $m$  rows of constraints; that means,  $m$  equality constraints in and we have  $n$  variables and  $m$  is less than  $n$ . So,  $m$  is less than  $n$ ; that means, you have number of variables more than the number of constraints.

So, these needs to infinite number of feasible solutions, so, we have a system where you have more variables fewer equations. So, this leads to infinite number of feasible solutions and therefore, the selection of best feasible solution that maximizes the objective function is not a trivial problem.

It is not an easy problem, to generate the solutions; let us first use first  $m$  variables to reduce the system to canonical or row echelon form by Gauss Jordan elimination. So, you have  $m$  constraints  $n$  variables and  $m$  is less than  $n$ . So, I can choose any  $m$  variables and then can reduce the system to a canonical form or row echelon form. So, the remaining variables I can set to 0 and can solve for  $m$  variables because, you have  $n$  variables and  $m$  equations in that case you can solve only for  $m$  variables.

So, what we do is we take the first  $m$  variables  $x_1, x_2, \dots, x_m$  and reduce the system to canonical or row echelon form by say Gauss Jordan elimination method.

(Refer Slide Time: 29:59)

**Transformation to Canonical Form: General Case**

By performing  $n$  pivotal operations for any  $m$  variables (say,  $x_1, x_2, \dots, x_m$ ) called **pivotal variables** the system of equations can be reduced to canonical form as follows:

$$\begin{aligned} 1x_1 + 0x_2 + \dots + 0x_m + \bar{a}_{1,m+1}x_{m+1} + \dots + \bar{a}_{1s}x_s + \dots + \bar{a}_{1n}x_n &= \bar{b}_1 \\ 0x_1 + 1x_2 + \dots + 0x_m + \bar{a}_{2,m+1}x_{m+1} + \dots + \bar{a}_{2s}x_s + \dots + \bar{a}_{2n}x_n &= \bar{b}_2 \\ \vdots & \vdots \\ 0x_1 + \dots + 1x_r + \dots + 0x_m + \bar{a}_{r,m+1}x_{m+1} + \dots + \bar{a}_{rs}x_s + \dots + \bar{a}_{rn}x_n &= \bar{b}_r \\ \vdots & \vdots \\ 0x_1 + 0x_2 + \dots + 1x_m + \bar{a}_{m,m+1}x_{m+1} + \dots + \bar{a}_{ms}x_s + \dots + \bar{a}_{mn}x_n &= \bar{b}_m \end{aligned}$$

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES

So, by performing  $n$  pivotal operations for any  $m$  variables say  $x_1, x_2, \dots, x_m$  call pivotal variables the system of equations can be reduced to canonical form as shown. So, we have  $n$  variables and  $m$  equations, so, first focus your attention on first  $m$  variables. So, this part is similar to  $m$  by  $n$  square system. So, here I will have canonical form as discussed in  $m$  by  $n$  square system and I can do this by doing the pivotal operations or doing these elementary row operations.

(Refer Slide Time: 31:25)

**Transformation to Canonical Form: General Case**

$$\begin{aligned} 1x_1 + 0x_2 + \dots + 0x_m + \bar{a}_{1,m+1}x_{m+1} + \dots + \bar{a}_{1s}x_s + \dots + \bar{a}_{1n}x_n &= \bar{b}_1 \\ 0x_1 + 1x_2 + \dots + 0x_m + \bar{a}_{2,m+1}x_{m+1} + \dots + \bar{a}_{2s}x_s + \dots + \bar{a}_{2n}x_n &= \bar{b}_2 \\ \vdots & \\ 0x_1 + \dots + 1x_r + \dots + 0x_m + \bar{a}_{r,m+1}x_{m+1} + \dots + \bar{a}_{rs}x_s + \dots + \bar{a}_{rn}x_n &= \bar{b}_r \\ \vdots & \\ 0x_1 + 0x_2 + \dots + 1x_m + \bar{a}_{m,m+1}x_{m+1} + \dots + \bar{a}_{ms}x_s + \dots + \bar{a}_{mn}x_n &= \bar{b}_m \end{aligned}$$

Variables,  $x_{m+1}, \dots, x_n$  of above set of equations is known as *non-pivotal variables* or independent variables.

The variables  $x_{m+1}$  to  $x_n$  of the above set of equations is known as non pivotal variables or independent variables; so,  $x_1$  to  $x_m$  are pivotal variables and  $x_{m+1}$  to  $x_n$  are non pivotal or independent variables.

(Refer Slide Time: 31:53)

**Basic Variables, Basic Feasible Solution**

One solution that can be obtained from the above set of equations is:

$$\begin{aligned} x_i &= \bar{b}_i \quad \text{for } i = 1, \dots, m \\ x_i &= 0 \quad \text{for } i = (m+1), \dots, n \end{aligned}$$

This solution is known as *basic solution*.

Pivotal variables,  $x_1, x_2, \dots, x_m$ , are also known as *basic variables*.

Non-pivotal variables,  $x_{m+1}, \dots, x_n$ , are known as *non-basic variables*.

**Basic solution** is also known as **basic feasible solution** because it satisfies all the constraints as well as non-negativity criterion for all the variables

So, one solution that can be obtained from the above set of equation is ;  $x_i$  equal to  $\bar{b}_i$  for  $i$  equal to 1 to  $m$  and  $x_i$  equal to 0 for  $i$  equal to  $m+1$  to  $n$ .

So, how all we are doing is we are setting  $x_{m+1}$  to  $x_n$  as 0. Then the solution can easily be obtained as  $x_1$  equal to  $b_1$  bar  $x_2$  equal to  $b_2$  bar  $x_n$  equal to  $b_m$  bar and  $x_{m+1}$  equal to 0 up to  $x_n$  equal to 0.

So, one solution that can be obtained easily from the above set of equation is  $x_i$  equal to  $b_i$  bar for  $i$  equal to 1 to  $m$  and  $x_i$  equal to 0 for  $i$  equal to  $m+1$  to  $m$  this solution is known as basic solution. The pivotal variables  $x_1$   $x_2$  up to  $x_m$  are also known as basic variables, non pivotal variables  $x_{m+1}$  to  $x_m$  are known as non basic variables. Basic solution is also known as basic feasible solution because; it satisfies all the constraints as well as non negativity criterion for all the variables

So, what we learn that we can convert a set of linear equations in  $n$  variables  $m$  constraints or  $n$  equations to an equivalent canonical form and then if I take the first  $m$  variables as basic variables; the remaining  $m+1$  to  $n$  variables as non basic variables, I can set those non basic variables to 0 and can solve for the basic variables. The basic solution is also known as basic feasible solution, because it satisfies all the constraints.

The slide is titled "Optimization in Chemical Engineering" in red text at the top. In the center, the words "Thank You" are written in large, bold, red font. To the left of the text is a 3D surface plot of a yellow and orange curved surface. To the right is a network diagram of the United States with nodes and connecting lines in purple and blue. Below the main content are four small images: a chemical plant, another chemical plant, a third chemical plant, and a control room with multiple computer monitors. At the bottom left is the IIT Kharagpur logo, and at the bottom center is the NPTEL Online Certification Courses logo. A small inset video of a man in a blue shirt is visible in the bottom right corner.

With this we stop our discussion on lecture 40 or week 8 here. In the next week, we will talk about simplex method and these concepts of basic solution basic feasible solutions we will utilize for discussion on simplex methods.
