**Lecture – 16**  
**Navier-Stokes equation for simple cases of flow**

In the last tutorial lecture, we have derived the constitutive equation for a Newtonian fluid. Let us summaries the arguments for this.

(Refer Slide Time: 00:23)

**Constitutive Relation for a Newtonian Fluid**

- Linear momentum balance:  $\frac{\partial(\rho u_i)}{\partial t} + \frac{\partial(\rho u_i u_j)}{\partial x_j} = \frac{\partial(\sigma_{ji})}{\partial x_j} + \rho g_i$
- Assume that  $\sigma_{ij} = -p \delta_{ij} + \tau_{ij}$   
 where  $p$  = pressure and  $\tau_{ij}$  is the stress induced due to motion
- Newtonian fluid obeys :  $\tau_{ij} \propto \epsilon_{mn} = \partial u_m / \partial x_n$   
 or  $\tau_{ij} = A_{ijmn} \epsilon_{mn}$  where  $A_{ijmn}$  is a matrix with 81 constants
- Assume
  - solid body rotation does not cause stress
  - fluid is isotropic
- to get a relation involving only two constants:

$$\tau_{ij} = \mu \left( \frac{\partial u_i}{\partial x_j} + \frac{\partial u_j}{\partial x_i} \right) + \lambda \frac{\partial u_k}{\partial x_k}$$

We have linear momentum balance equation applied gives us this equation here,  $\frac{\partial(\rho u_i)}{\partial t} + \frac{\partial(\rho u_i u_j)}{\partial x_j} = \frac{\partial(\sigma_{ji})}{\partial x_j} + \rho g_i$ , which is a body force. Now, in this case this has three equations, but too many unknowns here and even if you invoke the angular momentum balance equation, we will have too many of the stresses here that are unspecified.

So, we said that we break up the stress into hydro static components involving pressure as a compressive force, which is always normal and compressive, which is why we have the  $\delta_{ij}$  plus shear stress viscous stress which is induced due to relative motion and we studied the kinematics of deformation and we suggested that the deformation rates can be expressed in terms of linear combinations of this a deformation tensor and we seek a linear relation between the stresses that are induced by relative motion and the strain rate that are produced as a result of this relative motion, such that since this strain

rate are expressible in terms of linear combination of the velocity gradients you could replace the stresses here by the velocity gradients here into this, so that we can get rid of all these unknowns.

In the general case, we have this linear relation having 81 constants but, if you assume the solid body rotation not causing any stress because there is no deformation it is just rotation and stress translation, fluid translation does not produce any deformation rate. If we say that this is not causing any stress then this tensors here becomes asymmetric tensors expressed in terms of the  $d_{mn}$  and there are other arguments also given raise to the same idea there and if you make the further assumption of fluid being isotropic then we have seen that the stress verses strain rate relation distortion strain rate relation can be expressed in terms of only two independent components constants which we call as  $\mu$  and  $\lambda$  here and the relation can be by expressed as  $\tau_{ij}$  as being given by  $\mu \frac{\partial u_i}{\partial x_j} + \mu \frac{\partial u_j}{\partial x_i} + \lambda \frac{\partial u_k}{\partial x_k}$ .

Now, we substitute this into this expression here and this into this expression and we finally get the conservation equation like this.

(Refer Slide Time: 03:19)

### Navier-Stokes Equations for Newtonian Fluids

- Continuity equation (mass conservation equation)
 
$$\frac{\partial \rho}{\partial t} + \frac{\partial(\rho u_i)}{\partial x_i} = 0$$
- Momentum conservation equation:
 
$$\frac{\partial(\rho u_i)}{\partial t} + \frac{\partial(\rho u_i u_j)}{\partial x_j} = -\frac{\partial p}{\partial x_i} + \frac{\partial}{\partial x_j} \left[ \mu \left( \frac{\partial u_i}{\partial x_j} + \frac{\partial u_j}{\partial x_i} \right) + \lambda \frac{\partial u_k}{\partial x_k} \right] + \rho g_i$$

- Four equations: 1 continuity + 3 momentum equations
- Four unknowns : u, v, w and p
- Fluid properties (density and viscosity) given by equation of state of the fluid

So, these are the Navier-Stokes equation for a Newtonian fluid and any flow of a Newtonian fluid is governed by these equations. We have a continuity equation or the mass conservation equation which is  $\frac{\partial \rho}{\partial t} + \frac{\partial(\rho u_i)}{\partial x_i} = 0$  and linear momentum conservation equation with the angular momentum all

thrown in with the Newtonian fluid assumptions thrown in that is the relation between stress and deformation strain rate is linear and the medium is isotropic.

So, those are the two assumptions of the Newtonian fluid and once we do that we can substitute that  $\sigma_{ij} = -p \delta_{ij} + \mu \left( \frac{\partial u_i}{\partial x_j} + \frac{\partial u_j}{\partial x_i} \right) + \lambda \frac{\partial u_k}{\partial x_k} \delta_{ij}$ . So, that it gives us minus  $\frac{dp}{dx_i}$  here plus  $\frac{\partial u_j}{\partial x_i}$  of the stress components here gives rise to this equation here and here we see that there are terms involving repeated index  $j$  here and repeated index  $j$  and repeated index  $i$  here and repeated index  $k$  here and all these things will give rise to a set of 4 equations; 1 is the continuity equation and 3 momentum equations here and these equations together have the three velocity components that is  $u, v, w$  in the Cartesian coordinate system and  $p$  pressure as the unknown variables and they also involve three material properties; the density, the first coefficient of viscosity and the second coefficient of viscosity.

So, if the fluid properties are given through an equation of state then we have four equations and four unknowns. So, this constitutes the set of Navier-Stokes equations and the formulation of the fluid flow problems. So, these four equations are the ones that we need to solve in order to describe any fluid flow situation. We also need to have a proper fluid domain in boundary conditions we will come to that later, but we will let us take a simplified form of this which is the case of incompressible constant property flow which for example, for most of the water flows without any heat transfer obey this kind of assumption.

(Refer Slide Time: 05:55)

### Incompressible, constant property N-S equations

- Continuity equation :
 
$$\frac{\partial u_i}{\partial x_i} = 0 \quad \nabla \cdot \mathbf{u} = 0$$
- Momentum conservation equation:
 
$$\frac{\partial u_i}{\partial t} + \frac{\partial (u_i u_j)}{\partial x_j} = -\frac{1}{\rho} \frac{\partial p}{\partial x_i} + \mu \frac{\partial^2 u_i}{\partial x^2} + \rho g_i$$
- In vector form (applicable in other coordinate systems):
 
$$\frac{\partial \mathbf{u}}{\partial t} + \nabla \cdot (\mathbf{u} \mathbf{u}) = -\frac{1}{\rho} \nabla p + \nu \nabla^2 \mathbf{u} + \mathbf{g}$$

So, in which case if you say that incompressible then density is constant. So, this becomes 0 here, rho can be taken out and then taken to the other side. So, we have  $\frac{\partial u_i}{\partial x_i} = 0$  that becomes the continuity equation here rho can be taken out and put here one by one by  $\frac{\partial u_i}{\partial x_i}$  here and mu can be replaced with the kinematic viscosity and since  $\frac{\partial u_i}{\partial x_i} = 0$  therefore,  $\frac{\partial u_k}{\partial x_k} = 0$ . So, this whole second coefficient drops out and you have a simplified momentum conservation equation which is like this. So, you have a simplified continuity equation and momentum conservation equation here for the case of incompressible constant property Navier-Stokes equations.

So, this can be written in the vector form as  $\nabla \cdot \mathbf{u} = 0$  and the momentum conservation equation can be written as  $\frac{\partial \mathbf{u}}{\partial t} + \nabla \cdot (\mathbf{u} \mathbf{u}) = -\frac{1}{\rho} \nabla p + \nu \nabla^2 \mathbf{u} + \mathbf{g}$  which is a dyadic tensor minus is an extra minus here one by rho gradient of pressure plus laplacian of the velocity vector plus the gravitational vector here.

So, this vectorial form here is good for us to write the corresponding equations in other coordinate systems like polar coordinate systems, cylindrical polar coordinate system or spherical coordinate system and you can go to standard text books to have the definitions of the divergence operator and the del square operator and the gradient operator. To rewrite this in any orthogonal coordinate system that you that you fancy or that applicable for a specific problem, for example, if you are looking at flow over a sphere

then instead of using the Cartesian coordinate system, you might want to use a spherical coordinate system then you can take this from and then define from books on mathematics, what is a divergence operator in spherical coordinate system? What are the correspond components here and here and the gradient here? And you can write down the governing equations for the case of incompressible constant property flow.

(Refer Slide Time: 08:49)

### Governing Equations for Incompressible, Constant Property Flow

- Continuity equation :
 
$$\frac{\partial u_i}{\partial x_j} = 0$$
- Momentum conservation equation:
 
$$\frac{\partial u_i}{\partial t} + \frac{\partial (u_i u_j)}{\partial x_j} = -\frac{1}{\rho} \frac{\partial p}{\partial x_i} + \nu \frac{\partial^2 u_i}{\partial x_j^2} + g_i$$
- Energy conservation equation:
 
$$\rho C_p \frac{\partial T}{\partial t} + \rho C_p \nabla \cdot (\mathbf{u} T) = k \nabla^2 T + \mu \Phi_v$$

So, this in a sense is the said to governing equations. We will come to the energy equation later.

(Refer Slide Time: 08:56)

### The Non-CFD Approach

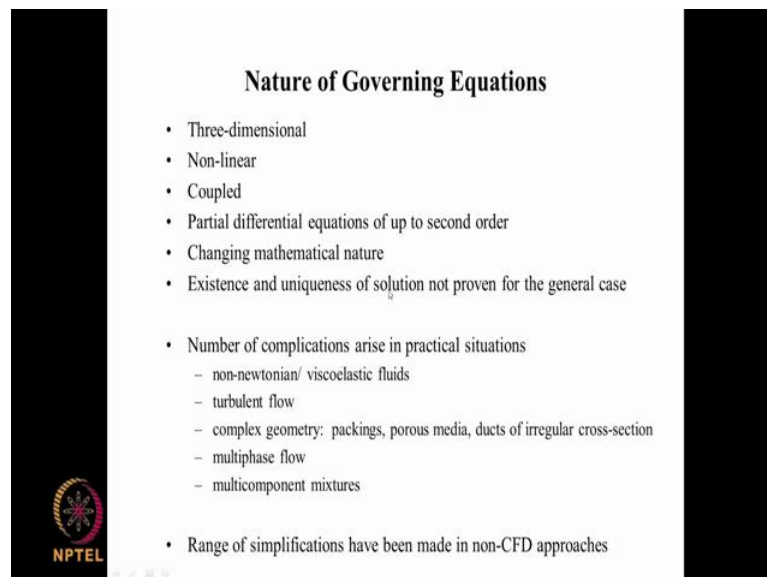

- Difficulties of solving governing equations
- Inviscid flow
- Creeping flow
- Fully developed flow
- Boundary layer flow
- Empirical approach

And before we consider this further we would like to draw the distinction between the CFD approach and the non-CFD approach in terms of the problem formation. So, that is, we know these equations, the equations that we solve often in CFD are not the same as the equations that we would solve in your analytical solution in the non-CFD approach, and that is because the equations which govern the fluid flow even though they look fairly simple like this only second order partial difference equation, but this is non-linear equation and you have three coupled equations and you have more problems in the sense of their not being of the same mathematical character all the time. So, we will come back to that. So, despite the apparent simplicity it is not possible to get analytical solution to the exact equations.

So, when we are doing the non-CFD approach then we make certain simplifying assumptions. These assumptions can be like inviscid flow, creeping flow, fully developed flow and boundary layer flow and all these things and we do not have to make these assumptions when we do the CFD. So, which is why it is important to see what we solve in CFD and what we solve in that in the analytical approach and that is the highlight that we are making here.

(Refer Slide Time: 10:38)

**Nature of Governing Equations**

- Three-dimensional
- Non-linear
- Coupled
- Partial differential equations of up to second order
- Changing mathematical nature
- Existence and uniqueness of solution not proven for the general case
  
- Number of complications arise in practical situations
  - non-newtonian/ viscoelastic fluids
  - turbulent flow
  - complex geometry: packings, porous media, ducts of irregular cross-section
  - multiphase flow
  - multicomponent mixtures
  
- Range of simplifications have been made in non-CFD approaches

 NPTEL

(Refer Slide Time: 10:39)

**Inviscid Flow**

- Viscosity = 0
- Momentum equations reduce to “Euler’s equations”
- Hyperbolic character of equations
- For steady flow along a streamline, Bernoulli’s principle:

$$p_1 + \rho g z_1 + \rho u_1^2 / 2 = p_2 + \rho g z_2 + \rho u_2^2 / 2$$

- Very useful in some cases
  - Cornerstone of aeronautical and turbomachinery applications
- But severe limitations in many cases
  - D’Alembert’s paradox: no drag or lift force from flow over a sphere
  - Coefficient of discharge from an orifice = 1

For example, in the distinction that we are trying to draw here, in inviscid flow we make the assumption of viscosity being equal to 0. So, then the momentum equations reduce to Euler’s equations and they become hyperbolic type of equation and for steady flow along the streamline you can have the momentum equations being written in the form of Bernoulli’s equation, Bernoulli’s principle  $p_1 + \rho g z_1 + \rho u_1^2 / 2 = p_2 + \rho g z_2 + \rho u_2^2 / 2$ .

So, this is another form of the governing equation which is very useful in many cases and it is been the cornerstone of aeronautical and turbo machinery applications long before computers were invented and widely used, but the inviscid flow assumption is not a practical assumption, for example, in many cases in cases you have the most famous of this is the D’Alembert’s paradox which means that if you have inviscid flow then you cannot have any drag force for flow over a sphere and similarly the coefficient discharge from an orifice will be equal to 1. So, those kinds of things are not practical and we know that when fluid flow is dragged and that phenomenon cannot be explained by the inviscid flow assumption.

(Refer Slide Time: 12:05)

### Creeping Flow

- $Re \ll 1$
- Convective terms are zero
- Equations reduce to transient or steady diffusion
- Parabolic/ elliptic character of equations
- Analytical solutions exist:
  - Stokes law for drag coefficient for flow over a sphere:  $C_D = 24 Re_d^{-1}$
  - Heat transfer from a sphere to stagnant surroundings:  $Nu_d = hd / \lambda = 2$
  - Mass transfer from a sphere to stagnant surroundings :  $Sh = 2$
  - also useful in flow through porous media and in lubrication theory
- Relations not valid for  $Re > 1$ , note  $Re_{crit}$  for sphere  $\sim 200\,000$

Another assumption that we make is the creeping flow assumption and here we are assuming that the Reynolds number is much, much less than 1. So, that the convective terms are set to 0 and equations reduce to transient or steady diffusion and these are primarily parabolic or elliptic in nature and you have some analytical solutions, for example, Stokes law for drag coefficient over a sphere is expressed in terms of 24 by Reynolds number and heat transfer from a sphere to stagnant surroundings.

So, you have certain analytical results which are useful, but these are useful in some special circumstances that are Reynolds number much, much less than 1. So, these are not valid for Reynolds number greater than 1 and Reynolds number greater than 1 is not such an unusual thing, for example, the critical Reynolds number at which laminar turbulent transition takes place for a sphere a flow over a sphere is a Reynolds number of something like 200,000 not 2100 not 2300 not 1000, it is 200,000. So, whereas, this relation here, the Stokes law assumption is valid for Reynolds number less than 1. So, in many cases we cannot make use of this.

(Refer Slide Time: 13:44)

### Fully developed Flow

- Analytical treatment of turbulent flow requires velocity profile, e.g. 1/7th power law
  - friction factor =  $0.046Re^{-1/5}$
  - convective heat transfer,  $Nu = 0.023Re^{0.83} Pr^{0.33}$      $Pr$  = Prandtl no.
  - mass transfer coefficient,  $Sh = 0.023Re^{0.83} Sc^{0.33}$      $Sc$  = Schmidt no.
  - Non-circular geometries can be handled through use of the hydraulic diameter concept:  $D_h = 4 \times \text{flow cross sectional area} / \text{wetted perimeter}$
- Relations not valid for short ducts or for non-straight ducts which is often the case in practice

Another assumption that we often make in order to get some insight into fluid flow is the fully developed flow assumption. So, gradients in the flow direction except for driving force such a pressure, temperature and concentrations. We say that the gradients are 0 of other quantities and the gradients of these quantities are constant. So, that we reduce the problem to one-dimensional flow and you have only one non-zero velocity component and you have an elliptic character of equation.

We will come back to that and we have Poiseuille flow in a pipe for which you have friction factor, which is defined which can be obtained as  $16/Re$  by Reynolds number where the friction factor here is defined as the shear stress divided by half  $\rho u^2$ , where  $u$  is the average velocity and you also have the convective heat transfer coefficient expressed in terms of Nusselt number is  $4.364$  per wall heat flux constant and  $3.65$  for a temperature wall temperature constant cases. So, you can get these useful relations, but these are valid for laminar flow and only for the case of fully developed flow. If you have developing flow then this not valid, you also have certain relations for turbulent flow, but these are not valid for short ducts or non straight ducts which is often the case as we saw in the very first lecture of this course. We saw certain cases where you do not have fully developed flow and you do not have ducts of a constant cross section. So, in such a case applications of these relations become questionable.

(Refer Slide Time: 15:40)

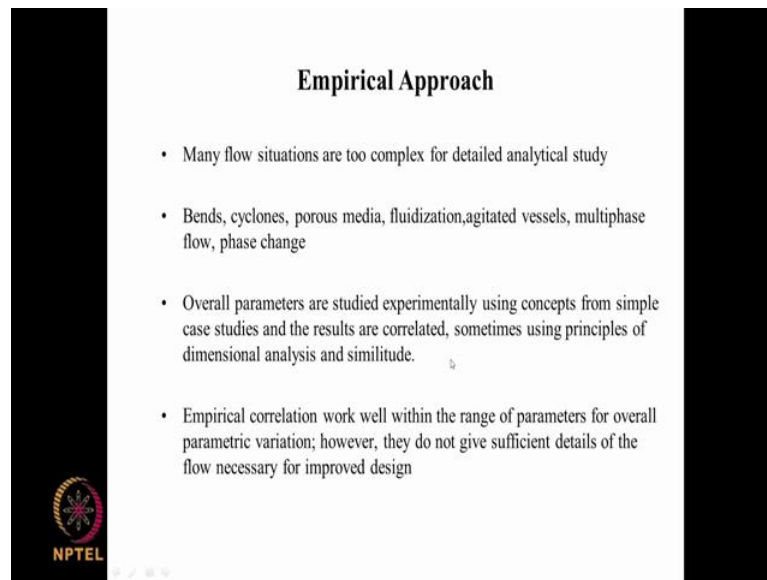

### Boundary Layer Flow

- Gradients along flow direction are much less than those perpendicular to the surface in the vicinity of a solid wall.
- Away from wall, the flow is virtually inviscid
- Can be used to handle developing flow (the entry flow) problem in a pipe
- Laminar flow over a flat plate yields a similarity solution
  - friction factor,  $f_x = 0.332\text{Re}^{-1/2}$
  - convective heat transfer,  $\text{Nu}_x = 0.332\text{Re}^{1/2} \text{Pr}^{1/3}$  Pr = Prandtl no.
  - mass transfer coefficient,  $\text{Sh}_x = 0.332\text{Re}^{1/2} \text{Sc}^{1/3}$  Sc = Schmidt no.
- Relations not valid for bluff bodies, separated flows and at the stagnation points.

And again one more common assumption that we make is the boundary layer flow in order to get some analytical results and so gradients in along flow direction is much less than those perpendicular flow to the surface in the vicinity of the solid wall and well away from the wall, the flow is virtually inviscid and it can be used to develop, handle developing flow, for example, the entry flow in a problem in a pipe can be done using this kind of thing and you have useful relation for a laminar flow over a flat plate. You have certain relations for the friction factor and then for heat transfer coefficient and mass transfer coefficient, but these relations are not valid for bluff bodies, so that means, in the sense, where you do not have a thin boundary layer and you have strong where a pressure gradients and non-cylinder bodies where the  $l$  by  $d$  ratio isahsmall its not very large and also for separated flows and very close to stagnation points where the boundary layer thickness is large compared to the distance it covers along the surface. So, these are all useful things, but these are not for the general case

(Refer Slide Time: 17:05)

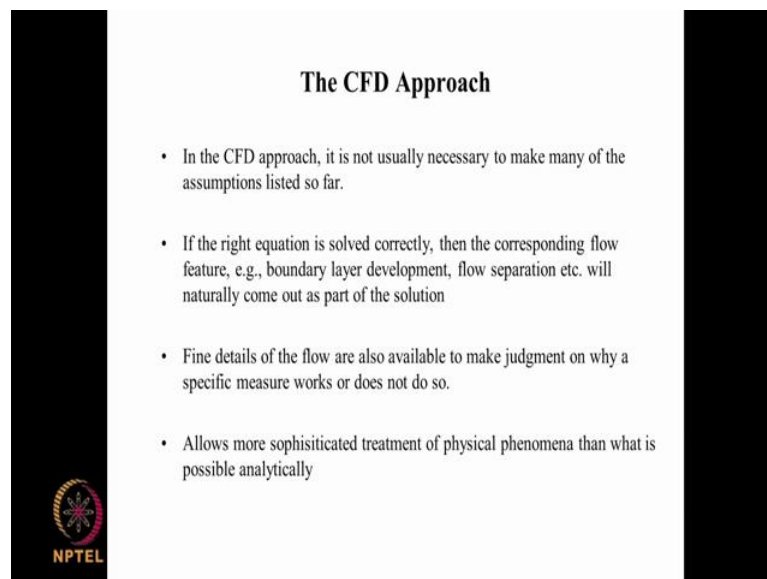

### Empirical Approach

- Many flow situations are too complex for detailed analytical study
- Bends, cyclones, porous media, fluidization, agitated vessels, multiphase flow, phase change
- Overall parameters are studied experimentally using concepts from simple case studies and the results are correlated, sometimes using principles of dimensional analysis and similitude.
- Empirical correlation work well within the range of parameters for overall parametric variation; however, they do not give sufficient details of the flow necessary for improved design

And we can also do the empirical thing.

(Refer Slide Time: 17:08)

### The CFD Approach

- In the CFD approach, it is not usually necessary to make many of the assumptions listed so far.
- If the right equation is solved correctly, then the corresponding flow feature, e.g., boundary layer development, flow separation etc. will naturally come out as part of the solution
- Fine details of the flow are also available to make judgment on why a specific measure works or does not do so.
- Allows more sophisticated treatment of physical phenomena than what is possible analytically

But these are not for the general case in the general case we have only the Navier-Stokes equations that are applicable and these are the things that we try to solve. So, that when we solve the CFD problem, we do not make any assumptions as to whether the flow is the creeping flow, whether it is boundary type of flow or fully developed flow and all that.

These things come in the specification of the flow domain and the boundary conditions which we will see later on and we specify those boundary conditions, and we identify the flow domain if the flow happens to be creeping flow because the velocity that is specified is small then the creeping flow solution will emerge from your CFD conclusions and if the flow velocity is high and there is a boundary layer type of behaviour is expected then your CFD simulations will show a boundary layer type of flow solutions.

If you were to draw the velocity profiles, you see that the velocity gradients are very large close to the wall and away from the wall. They are very small, you do not have to make the assumption of boundary layer, you do not have to identify the thickness you just have to specify the boundary conditions and identify the flow domain.

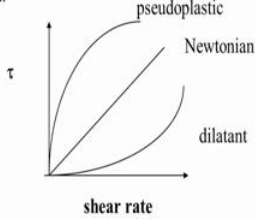

So, we do not make these assumptions. We start with the flow governing equations and then we solve this, so that is important point that I want to mention here that in when we are doing the CFD we solve the fundamental equations which is a consideration of mass momentum and we will see later on energy equations without any assumptions. So, that gives the strength of argument for the goodness of the CFD solution whereas, if we have to make any assumption about creeping flow or flow and all that then we need to have very low velocities.

In the case of creeping flow and very long ducts in the case of the same cross section, in the case of fully developed flow those things are not found in practice and so those assumptions are defeating when you want to apply to practical case, but we do not have that limitation with CFD, but the equations that we have derived are not universally always valid. So, that is another important point that we have to bring out keep in mind.

(Refer Slide Time: 19:54)

### Non-newtonian Fluids

- For many process fluids, such direct proportionality does not hold good and a more complicated non-newtonian rheological behaviour is expected.

- Shear stress vs shear rate relation can also be time-dependent
- More complicated behaviour is exhibited by viscoelastic fluids ("fluids with memory") where the relation depends on the history of stress and strain suffered by the fluid element

When we apply these equations and one of the simplest assumptions situations where the CFD equations that we are writing down, the Navier-Stokes equation that we are writing down can be questioned is for non-Newtonian fluids.

We have made an assumption of a linearity between shear stress and the shear rate or the strain rate shear strain rate and so that is the linear assumption, but there are number of fluids which exhibits a non-linear variation. This kind or relation where and you can also see this kind of you have a pseudoplastic or dilatant variation and you can have variation with respect to time, and we can also have more complicated behaviour like that of a viscoelastic fluid, where the shear rate or the stress verses shear rate does not depend on the local values.

The stress does not depend on just the shear rate that it is present locally. So, that is train not just equal to  $\mu \frac{du}{dy}$  at a particular point  $\tau$  at a particular point  $xy$  is not equal to  $\mu \frac{du}{dy}$  at  $xy$ , but it also depends on the previous history, time history of the deformation that the fluid element has gone through.

When we say previous history, we can only handle short distance, short memory kind of things, but it is it exhibits therefore; a solid like behaviour and a fluid like behaviour and these are called viscoelastic fluid.

(Refer Slide Time: 21:42)

### Modelling of Non-newtonian Fluid Behaviour

- One of the simplest non-newtonian models is the “power law” fluid or the Ostwald de Waele model. Here, the viscosity is expressed in terms of two parameters, viz., K, the consistency index and n, the flow behaviour index:

$$\mu = K(\dot{\gamma})^{n-1} \quad \text{where } \dot{\gamma} = \sqrt{2(D:D)} \quad D = \frac{1}{2}(\nabla u + \nabla u^T)$$

- $n < 1$  pseudoplastic or shear thinning fluids
- $n > 1$  dilatant or shear thickening fluids
- A more complicated behaviour can be locally represented by a power-law model
- Note that viscosity variation with pressure or temperature does not make the fluid non-newtonian!

So, that is much more complicated, modelling that is required for this. So, that kind of non-Newtonian fluid behaviour is something that our equations that we are solving in this course are not applicable.

(Refer Slide Time: 21:51)

### NOT APPLICABLE!

- Non-newtonian fluids
- Flow through porous media
- Grid movement
- Turbulent flow
- Multiphase flow

SPECIAL FORMS OF EQUATIONS ARE REQUIRED FOR ALL THESE CASES

So, there are also other cases like flow through porous media in which the equations that we have derived are not applicable because part of the flow domain is occupied by the solid only part of it is available for flow and even then you do not have a simple straight forward flow through that, you can have interconnected porous of varying cross section

and all that. So, that requires a special treatment and that treatment is not there in the equations that we have derived, for example, and similarly grid movement calls for extra terms which are related to the velocity of the grids. So, there again these equations in the form that we have derived are not applicable.

Turbulent flow is a very special case where we are getting chaos, chaotic type of flow behaviour from the deterministic equations that we have derived and. So, there is lot of theory behind that and then we have to have special forms of equations for that similarly when we have the multiphase flow where we do not have a single fluid single phase, but two phases then again we have some special considerations that come into picture.

So, all these practical cases, we have to have an extended set of equations and the equations that we have derived are not any longer fundamental. So, what we claim as fundamental equations are essentially fundamental under certain special cases, but these are generic enough that the solutions of these is still interesting and there is also further mathematical treatment and extra equations that we can derive for all these things, all these physical phenomena and in all the cases the resulting equations can be solved using the techniques that we are going to discuss in the rest of the theory.

So, we would like to look at how to solve this simplified form of the special form of the equations that we have derived, which is the Navier-Stokes equations for a Newtonian single phase fluid and then. So, that armed with that we can then solve the extra equations that come into picture, when we are dealing with all the more complicated physical phenomena.

The objective of this lecture, this part of the module is to formulate the problem or the mathematical problem for especially derive the fundamental equations that we are going to solve for the, rest of the course and these fundamental equations are applicable for single phase laminar flow often Newtonian fluid. In the last part of this last module of this course, we look at the equations that can be used for turbulent flow, but otherwise we are assuming laminar flow and these equations are in a special form, these equations are in the form of coupled non-linear partial differential equations and these equations are 4 in number for the simplest case and involve four variables  $u$ ,  $v$ ,  $w$ ,  $p$  in the case of Cartesian coordinate system and they require us to specify the density and viscosity and the two coefficient of viscosity for the general case.

So, with these things we can go into solutions of the equations, but before we do that we would like to bring in the considerations about the boundary conditions and initial conditions because we have these are partial differential equations. So, the mathematical problem is not complete without specification of the boundary and initial conditions and we would also like to look at a allied phenomenon which go along with the fluid flow and the allied phenomenon are the heat transfer the mass transfer and the chemical reactions that are usually of interest to practicing engineers.

It maybe if you looking at a flow over a car then the equations that we have derived are sufficient for very low velocities, but for high velocities, we have turbulence and turbulent flow equations are extra things, but if you are looking at flow of inside a car and if you are looking at how the air conditioner works and all that, then you are bringing it in mass transfer, you need to be able to solve those kind of things. If you looking at what is happening inside the piston and how the fuel that you are putting into that is combusting and then producing power which is generating power to drive the wheels and then all that kinds of things, then you have to consider also the chemical reactions.

So, we are going to look at the mathematical formulation for flows with heat transfer, with mass transfer and with chemical reactions just the very framework of this. So, that we have the basic ideas that are coming in. And then we will briefly look at the boundary conditions, and what you mean by a well posed mathematical problem, where we have a set of equations, enough number of equations for the number of variables that are coming and the appropriate initial boundary conditions which will give us a unique solutions.

So, those are the things that we going to discuss in the second week of the second module dealing with governing equations.
