Tutorial 1 contd.: Solution for algebraic equation using Gauss- Seidel Method

We have seen now how to convert a partial differential equation into a set of algebraic equations into $AW = b$ type of matrix equation. In the particular case that we have looked at, we have a matrix with constant coefficients. It is not generally the case, but this is what we have.

Now, what we look at is how to solve this. Before we attempt the solution, we want to see whether this is going to give us a unique solution, do we have enough number of equations and are these equations independent, do we have a matrix equation which is irreducible, in the sense that there are, how do we know that some of these equations are not linear combinations of other equations.

(Refer Slide Time: 00:57)

So, that is a kind of question that we must ask ourselves. So, one normal way to look at that is to find out the determinant of A. But in a case like this, there are other thumb rules and other conditions; some of them are sufficient; some of them are necessary conditions, which can help us just by looking at it whether or not we can get a unique solution. One such condition is the condition of diagonal dominance.

So, we would like to use the condition of diagonal dominance to check whether we have the possibility of getting a unique solution. So, what do we mean by diagonal dominance? We have nine equations, and each of them is of this particular form, so where each of them is, for example, minus 1000 times w₂ plus 100 times w₃ plus 400 times w₂ equal to 0, like this.

So, when you have this set of this type of equations, we can define diagonal dominance as a condition where the modulus of the diagonal term. That is, in this matrix these are all the diagonal terms. So we have one term. The diagonal term is greater than or equal to the sum of all modulus of all other terms.

(Refer Slide Time: 03:00)

Condition of diagonal dominance
 $|a_{ii}| \geq \sum_{j \neq i} |a_{ij}|$ for each i

Strong form of diagonal dominance
 $|a_{ii}| > \sum_{j \neq i} |a_{ij}|$ for all i

Weak form of " " is satisfied by $Ax=b$

AND $|a_{ii}| \geq \sum_{j \neq i} |a_{ij}|$ for at least one i

Gauss-Seidel method \rightarrow iterative method
 $Ax=b \rightarrow Mx = Nx+b \rightarrow Mx^{k+1} = Nx^k + b$

That is, i not equal to j . So, this must be satisfied for each i . So, once we have this condition satisfied, we can claim diagonal dominance. So, if we have diagonal dominance, then we can say okay we have; that is one possibility, possible way of verifying that we have a unique set of equations, and we can get; where we can make use of some efficient method for the solution here.

So, we will, I will, we will have to edit somewhat here. So, in order to see how to proceed with the solution of this, we will look at the condition of diagonal dominance. And, the diagonal dominance can be expressed in this form, where the magnitude or the absolute value of the diagonal is equal to or greater than the sum of all the off diagonal elements in the same equation or in the same row. And, when this is satisfied with greater than symbol in all cases; that is known as the strong form of diagonal dominance. Ok

There is also a weak form of diagonal dominance, which is that the modulus of the diagonal term is greater than or equal to the sum of the modulus values, the magnitudes of all the other off diagonal terms for all i , that is, for all equations. And, the modulus of the diagonal term is greater than the sum of the modulus values of the off diagonal terms, at least for one equation.

So, we have here nine equations. If for all these nine equations this condition is satisfied, then we say we have strong form of diagonal dominance. But, if for all of these this condition is satisfied with either greater than or equal to sign, but there is at least one row for which this condition is satisfied with the greater than sign, then we say that we have a weak form of diagonal dominance.

So, let us now try to see what this diagonal dominance is. That if you look at the first row here, this represents one equation. And that equation, algebraic equation is for w_2 . And, in that equation the diagonal term is 1000. The magnitude is 1000 and the other off diagonal terms is 100 and 400. So, that is the sum of these two is 500, and this is 1000. So, this condition is satisfied for this equation. If we come to this, the diagonal term is 1000, magnitude is 1000. This is 100 plus 100, 200; 600; total is six hundred. So, this is also satisfying this condition here; here is again 1000 and the sum is 500. So, again this condition is satisfied. Here it is 400, 500, 900 and this is 1000. So, again this is satisfied.

For this equation here, 400, 500, 600, 1000 and this is 1000. So, this equation is not satisfied for this row, but for all the other rows this equation is satisfied. So, that means that this matrix here is not, does not satisfy the condition of strong form of diagonal dominance. But, if you look at the weak form, then even this equation satisfies this condition because in this case, it is equal to.

So, it is this equation, the diagonal dominance condition is not satisfied in the strong form, but it is satisfied in the weak form. And, for all the other equations it is satisfying this strong form of with a greater than sign. So, that means that our, we can claim that the weak form of diagonal dominance condition is satisfied by the set of $A w = b$ that we have. So, now when you have this kind of condition satisfied, the weak form is satisfied. This often arises in equations that we encounter in CFD, but not all the cases. But, this is a very desirable form because when you have this condition satisfied, a number of special techniques can be used to solve this equations $A w = b$ type of equations.

And, we make use of one such method known as Gauss-Seidel method for the solution of these equations. So, this is an iterative method. Ok. So, that means that we are not solving $A w = b$. So, this is put in the form of $M w = N w + b$. And, this is actually solved as $M w^{k+1} = N w^k + b$. Now, what this means is that k is known as the iteration number. So, we start with some initial guess. So, that is k values of all the w s are known. And then, we substitute this in this. And from this, we can get the $k+1$ th value here. And, once we get the $k+1$ th value, then we go back and put that here. And then, we again get an update thing.

So, we start with k equal to zero. Using this equation we get k equal to one. And then, you put k equal to one here, you get k equal to two. Put that into this, we get k equal to three and then we can keep on going like this, until we get a converge solution. We will get a converge solution, if we have the weak form of diagonal dominance for the condition A , for the matrix A . If we have coefficient matrix, which satisfies the weak form of diagonal dominance, this Gauss-Seidel iterative method will converge. No matter, what the initial guess is. So, when we are solving large sets of equations, when we are solving with lots and lots of grid points, then this becomes a very good method.

And, we will discuss this more in later weeks. Right now, we take it for granted that this is a method that we can use to solve these things. And, since our condition or quotient matrix A satisfies the weak form of diagonal dominance, this would be a good way of, good method for the solution of these equations.

Now, how do we actually do this? So, what we are actually doing is that we take each equation here and then we put the; we start with this; the first equation, this is minus 1000 w 2 2 plus 100 w 3 2 plus 400 w.

(Refer Slide Time: 12:33)

So, that is this is two three, wait, we have 3 2, 3 4, and 2 3. Yes. So, this is 3 2 and 2 3 equal to minus 1000. So, we can. in this equation, the diagonal term is always kept on the left hand side. And, so this is what we are looking for. We can rewrite this equation as minus 1000 w 2 2 equal to minus 1000 minus 100 w 3 2 minus 400 w 2 3. Ok.

So, now here we can put this as an iterative formula; w 2 2 k plus one equal to minus 1000 minus 100 w 3 2 k minus 400 w 2 3 k. So, if we know the initial conditions, initial values for this, then we can get this. So, we need to do this for each of the equations. So, in each equation the diagonal term is put on the left hand side. So, we have; from the first row we have this. And, from the second row we have minus 1000 w 3 2 k k plus one

equal to minus 1000. And then, we take the other one. This is minus 100 w 2 2. And then, we have minus 100 w 4 2. And then, we have one, two, three, four, five; one, two, three, four, five; minus 400 w 3 3.

Now, here this is 3 2 k plus one; two, two values already known from here because we solve this and then we come to this. So, we can put this as k plus one. And, at this time we have not yet solved for 4 2. So, we put this as k, and k. And, we come to the third equation. Here it is w 4 2. So, minus 1000 w 4 2 k plus one equal to minus 1000 minus 100 w 2 2; two, two values already known k plus one. So, this is not 2 2; so, this is 3 2. So, this is 3 2 is already known anyway. And then, we have 400 w 4 3.

And then, we can write this as; the next equation is for w 2 3. So, in this equation we come here. So, this is minus 400 w 2 2 k plus one. And, this is w 3 3 minus 100 w 3 3 k because that is not yet calculated. And then, we have this one here, which is w 2 4. So, in this way we write down all the nine equations. And, once we write down all the nine equations, we can get a sequential solution.

So, that is, we start with guess values for all the variables, and the guess values can be anything. They can be zero, they can all be the same or they can be any value. If you go through enough number of steps, then it will converge, provided we have the weak form of diagonal dominance or even the strong form of diagonal dominance.

So, we rewrite the nine equations that we have here, in this particular form. And then, we start with some initial guess values. And, using the guess values of w 3 2 and w 2 k, we use this to get w 2 at the first iteration. And then we come here, we evaluate w 3 2 at the first iteration, w 4 2 at the first iteration, 2 3, like this all the up to the last equation here.

So, we will be completing one sweep through all the nine points. So, starting with some zero values, zero iteration values, initial guess values, we will be getting the first set of values for all the nine. We substitute the first set of values from the right hand side, we get the second set of values, and then we put them in the second set and then we get third set, like that. If we keep on doing it, we find that gradually the numbers converge. So, something like this can be done, should be done, will have to be done on a computer. So,

we look at some solutions on the computer generated using the Gauss-Seidel method for this particular equation.

(Refer Slide Time: 18:45)

Table 1.1: Gauss-Seidel method for Case 1

for six unknowns

$$w_2^{k+1} = (1000 - 100w_1^k + 40w_3^k) / 1000$$

$$w_3^{k+1} = (2000 + 100w_2^k + 100w_4^k + 400w_1^k) / 2000$$

$$w_4^{k+1} = (1000 + 100w_2^k + 100w_3^k + 400w_1^k) / 1000$$

$$w_1^{k+1} = (1000 + 400w_2^k + 100w_3^k + 400w_4^k) / 1000$$

$$w_2^{k+1} = (1000 + 100w_3^k + 400w_4^k + 100w_1^k + 400w_1^k) / 1000$$

$$w_3^{k+1} = (1000 + 100w_2^k + 400w_4^k + 100w_1^k + 400w_1^k) / 1000$$

$$w_4^{k+1} = (1000 + 400w_2^k + 100w_3^k + 100w_4^k) / 1000$$

$$w_1^{k+1} = (1000 + 400w_2^k + 100w_3^k + 100w_4^k) / 1000$$

iter #	w21	w22	w23	w31	w32	w33	w34	w41	w42

Now, we have on the screen; we have the highlighted in yellow portion here, which contains all the nine equations which have been put up. We will just talk. I need to get one more. Should I start? Start?

(Refer Slide Time: 19:10)

Discretized Equations

$$w_{22}^{k+1} = (1000 + 100w_{32}^k + 400w_{23}^k)/1000$$

$$w_{32}^{k+1} = (1000 + 100w_{22}^{k+1} + 100w_{42}^k + 400w_{33}^k)/1000$$

$$w_{42}^{k+1} = (1000 + 100w_{32}^{k+1} + 400w_{43}^k)/1000$$

$$w_{23}^{k+1} = (1000 + 400w_{22}^{k+1} + 100w_{33}^k + 400w_{24}^k)/1000$$

$$w_{33}^{k+1} = (1000 + 100w_{23}^{k+1} + 400w_{32}^{k+1} + 100w_{43}^k + 400w_{44}^k)/1000$$

$$w_{43}^{k+1} = (1000 + 100w_{33}^{k+1} + 400w_{42}^{k+1} + 400w_{44}^k)/1000$$

$$w_{24}^{k+1} = (1000 + 400w_{23}^{k+1} + 100w_{34}^k)/1000$$

$$w_{34}^{k+1} = (1000 + 400w_{33}^{k+1} + 100w_{24}^{k+1} + 100w_{44}^k)/1000$$

$$w_{44}^{k+1} = (1000 + 400w_{43}^{k+1} + 100w_{34}^{k+1})/1000$$

So, we now have the set of nine equations, which we had them as $A w = b$, now, rewritten on the screen in the form of Gauss-Seidel method. Let us just go through the nine equations. We have equations for $w_{22}, w_{32}, w_{42}, w_{23}, w_{33}, w_{43}, w_{24}, w_{34}, w_{44}$. And, this is the order in which we solve sequentially. And, these each equation is written in the form of $w_{ij}^{k+1} = \dots$. So, that is, the updated value of w_{22} is given in terms of 1000 plus 100 times w_{32}^k . The old value of w_{32} plus old value of w_{23} , and this whole thing divided by 1000. So, the 1000 which was there as a coefficient of w_{22} has been brought on to the right hand side.

So, we have this first equation for w_{22}^{k+1} . And then, when you come to the second equation, this involves w_{22} . We have already evaluated this at $k+1$ iteration. So, we can make use of this. And, w_{42} is not known at $k+1$ level. It is known at the k th level or k th iteration. So, we substitute that. And, we substitute again the old value of w_{33} and then estimate the new value of w_{32} . And then, we come to w_{42} . Here w_{32} is known, so we have w_{32}^{k+1} . w_{43} is not known, we have w_{43}^k , as w_{22}^{k+1} , which is at $k+1$ and w_{24} and w_{34} are at k . Otherwise, the coefficients remain the same.

So, it is just rewriting of the equations in such a way that the term with the largest coefficient in magnitude. In this case, it happens to be the diagonal value. So, that particular thing is kept, brought to the left hand side and all the others are taken to the right hand side. And, if their value is known at k plus 1th level times step or iteration step, then we use it. Otherwise, we make use of the old iteration value; that is, k value likes this.

So, when you come to this a_{33} k plus one, here a_{33} is already computed here, so we make use of the latest value; a_{42} is already computed here, so we make use of the latest value; a_{44} is coming down further, so it is not known at the current k plus 1th iteration. We make use of the old value.

So, in this way we make a sequential evaluation of all the variables. In this case, we have nine variables. If we have nine thousand grid points, we will have nine thousand equations like this. And, we go through all the nine thousand equations at k plus 1th iteration level, before we move on to the next one. So, that is, Gauss-Seidel method is that we start with initial guesses; k equal to zero for all the variables. And then, we update each variable one by one in a sequential way like this. And, once we update all the variables, we go to the next iteration level. So, that is how the Gauss-Seidel method is supposed to work.

(Refer Slide Time: 22:40)

Discretized Equations

10	2.7679	3.1971	2.7697	3.6252	4.1118	3.6270	2.7698	3.1987	2.7707
11	2.7698	3.1987	2.7707	3.6270	4.1131	3.6278	2.7707	3.1994	2.7711
12	2.7707	3.1994	2.7711	3.6278	4.1138	3.6282	2.7711	3.1997	2.7713
13	2.7711	3.1997	2.7713	3.6282	4.1140	3.6284	2.7713	3.1999	2.7714
14	2.7713	3.1999	2.7714	3.6284	4.1142	3.6285	2.7714	3.1999	2.7714

And, this is the way that these are the values that we have got as a function of iteration number. So, iteration number of zero corresponds to initial guess. So, this is all of these or with an initial guess of zero, it can be anything. So, we started with some initial guess. And then, we updated this first and then this and then this and then this, this, this. Like this, we updated all the values, using the formulas that we have derived by rewriting $A w = b$ form.

And then, once we evaluate all these things, then we come to the next iteration level. We reevaluate this, reevaluate this, reevaluate all these things. And, we can see that we take any value, it started with zero, one, one point six seven, two point one seven, two point four six. It is the incremental value is becoming smaller and smaller and smaller. And then, you can see that at the end of fourteen iterations, it has come down to two point seven seven one three. So, the increment is only point zero zero zero two. And, this one is also increment is in the last decimal place here; in the fifth, fourth decimal place here and here like this. And if we increase the, if we go further and further, we will see that even the fourth decimal place will not change, the fifth decimal place will change. So, depending on what accuracy of solution you want, you can stop after so many number of iterations. And, so this is how the Gauss-Seidel method works. You start with the, you rewrite your original set of $A w = b$ equations, which you got by discretizing the

partial differential equation using finite difference approximations. And, you check whether the coefficient matrix A satisfies either the weak form or the strong form of the diagonal dominance. And if it does satisfy, then you can make use of the Gauss-Seidel method, and rewrite the equations in this k plus one and k form in a particular way, which will discuss in later classes.

And, once you have these formulas, then it is just a sequential iteration of this with any initial guess. It need not to be the same for all the variables, but it does not matter what they are, eventually they will converge. There is a guarantee of convergence, provided the equations are linear and they are irreducible, and they satisfy the weak form of diagonal dominance.

So, in such a case we can make use of the Gauss-Seidel method and get a solution like this. And, you can see it is converging to some value and the values are not the same in all the cases. There are some, which are smaller and some which are higher. The highest value is four point one and the smallest value that we have got is two point seven seven. And, how is this correct? Four point one one is for w_{33} . And, w_{33} happens to be; the w_{33} happens to be the value, which is right at the center of the domain which is farthest from all the walls. So, it will have the highest value.

And that kind of logic is followed. w_{23} and w_{43} are symmetric. And, you can see that they have very similar values; three point six two eight four, three point six two eight five. If you take it to convergence, they both will be the same. And similarly, the symmetry between w_{42} and w_{24} , again between w_{32} and w_{34} . So, we could have made use as symmetry. But, for the illustration we are showing that you have a certain variation of velocity, which is consistent with our understanding or expectation that as you move further and further away from the walls, the velocity will be higher. And that is what we get.

In ideal case having nine unknowns here, it is not going to give us a lot of accuracy because this is a very gross error. And, if you were to calculate the average velocity from by taking the average of all these things, then it may not match with the expected value; because the number of grid points is very small here. So, if you make it instead of five by

five, if you make it ten by ten or twenty by twenty or fifty by fifty, then you will see that the solution that you get will be converging. So, that is further increase of a grid points will not make any difference. And, at that point you can say that you have got the correct solution. Ok. So, this is the essence of CFD approach.

And, the CFD approach is that you start with the equations which describe mathematically the flow. And, in this particular case we have that $\frac{\partial^2 u}{\partial x^2} + \frac{\partial^2 u}{\partial y^2} = \text{constant}$. So, that is a partial differential equation; the solution of which we are seeking and we do not get a value at any x and y . We get a value at specified values of x and y . These are known as the grid points. So, wherever you want to have a solution, there you discretize the governing equation by substituting different formulas for the derivatives.

So, the derivatives expressed in terms of values of the variable at discrete points. And that will give you a set of algebraic equations. And, the set of algebraic equations together are determinate. And, you can solve them by using a number of methods. And, what we have seen for the purpose of illustration is a special method, which is often used in CFD, which is the Gauss-Seidel method. And, we can see that. Using this method, we can get a solution using elementary mathematics. In order to get the solution, we did not have to use any special mathematics. It is just simple finite difference approximations and solution of algebraic equations. And, that is the advantage of CFD. And, we can use this same principle for even more complicated equations. So, that is; and that is what enables us to use this CFD approach for the solution of the much more complicated equations, which describe fluid flow in any arbitrary geometry. But, we are still a long way from it.

Before we get to discussion of those complications and all that, in the next module, in the next week, we look at a different way of doing the same thing. A different way of converting a partial differential equation into a set of algebraic equations this time. In this method, we have used finite differences and we will use finite volume method to do the same thing and end up with again a set of algebraic equations, which can again be solved using the Gauss-Seidel method. And, the difference between that finite difference and finite volume method, we will see in the next lecture. And hopefully, you will learn

from that that one could tackle even more complicated geometries than this very simple geometry that we have done today.
