Lecture - 25
Non-dimensional analysis - 3 Buckingham Pi Theorem

So, we were looking at Buckingham Pi Theorem in the last class. Let us just go through it once again so, that you get it straight.

(Refer Slide Time: 00:23)

So, we really did not complete the theorem that day. So, let me just state the theorem. So, we actually what we did is we actually try to do an example. So, what it says is that if a physical process involves n variables which contain j dimensions, then relationship containing k non dimensional variables can be written down and k will be greater than or equal to n minus j ok.

So, suppose you have a physical process, which contains let us say n variables and it involves j dimensions then you can find a k which is n minus j or greater than n minus j and you will be able to find k non dimensional groups and you will be able to write down a relation between them.

(Refer Slide Time: 02:37)

So, the problem that we had was some object with a characteristic dimension L and a fluid approaching it with a velocity U and has parameters sorry the properties density ρ and viscosity μ and you were interested in calculating what is the force exerted by the object on the fluid. And you said that is actually going to be a function of you know U , ρ and μ .

$$F = f(U, L, \rho, \mu)$$

And we said we have identified now, 5 different variables and we will write down the dimensions of each of them. So, So that means, we have identified n is equal to 5 j can be 3 because its mass length and time and therefore, we should find k which is equal to 5 minus 3 2 two non dimensional variables that we should be able to identify and then we said that we have to select the repeating variables first.

$$[F] = MLT^{-1}$$

$$[U] = LT^{-1}$$

$$[L] = L^1$$

$$[\rho] = ML^{-3}$$

$$[\mu] = ML^{-1}T^{-1}$$

(Refer Slide Time: 04:19)

So, j repeating variables which we chose as length U and ρ and therefore, we wrote down our first combination π_1 . And we said that has to be equal to a non dimensional number; that means

$$(MLT^{-2})(L)^a(LT^{-1})^b(ML^{-3})^c = M^0L^0T^0$$

$$\pi_1 = \frac{F}{\rho U^2 L^2}$$

So, then we can talk about the next parameter.

(Refer Slide Time: 05:59)

Handwritten derivation of the second non-dimensional number π_2 using the Buckingham Pi theorem. The derivation shows the relationship between the variables μ , L , U , and ρ and their dimensions M , L , and T .

$$\pi_2 = \mu L^a U^b \rho^c$$

$$[\pi_2] = (M L^{-1} T^{-1}) (L)^a (L T^{-1})^b (M L^{-3})^c = M^0 L^0 T^0$$

$$1 + c = 0 \Rightarrow c = -1$$

$$-1 - b = 0 \Rightarrow b = -1$$

$$-1 + a + b - 3c = 0 \Rightarrow a = 1 + 3c - b$$

$$\Rightarrow 1 - 3 + 1 = -1$$

$$\pi_2 = \mu L^{-1} U^{-1} \rho^{-1} = \frac{\mu}{\rho U L}$$

So, the second non-dimensional number π_2 can be generated with μ ;

$$\pi_2 = \mu L^a U^b \rho^c$$

$$[\pi_2] = [M L^{-1} T^{-1}] [L]^a [L T^{-1}]^b [M L^{-3}]^c = M^0 L^0 T^0$$

Therefore,

$$1 + c = 0 \rightarrow c = -1$$

$$-1 - b = 0 \rightarrow b = -1$$

$$-1 + a + b - 3c = 0 \rightarrow a = -1$$

$$\pi_2 = \mu L^{-1} U^{-1} \rho^{-1} = \frac{\mu}{\rho U L}$$

(Refer Slide Time: 08:25)

[illegible]

Buckingham pi theorem says that there exists a relationship between π_1 and π_2

$$\pi_1 = \frac{F}{\rho U^2 L^2}$$

$$\pi_2 = \frac{\mu}{\rho UL}$$

$$\frac{F}{\rho U^2 L^2} = g(Re)$$

So, this is one way of doing it there is another way of doing it which is relatively simpler and it is known as Ipsen's method.

(Refer Slide Time: 09:17)

Ipsen's method $\rightarrow$ Systematically eliminate dimensions

$$F = f(L, U, \rho, \mu)$$

$\underbrace{\hspace{1.5cm}}_{MLT^{-2}} \quad \underbrace{\hspace{0.5cm}}_L \quad \underbrace{\hspace{0.5cm}}_{LT^{-1}} \quad \underbrace{\hspace{0.5cm}}_{m^{-3}} \quad \underbrace{\hspace{0.5cm}}_{ML^{-1}T^{-1}}$

So, in this case so, we will look at the same problem and try to derive the same relationship, but in a slightly different procedure. We will write we want to get force as a function of what all things L U ρ μ that is our intention at the moment. The first thing that you do is again write down the dimensions of each of them:

$$F = f(U, L, \rho, \mu)$$

$$[F] = MLT^{-1}$$

$$[U] = LT^{-1}$$

$$[L] = L^1$$

$$[\rho] = ML^{-3}$$

$$[\mu] = ML^{-1}T^{-1}$$

So, in this method what you have to do is you have to systematically eliminate dimensions ok. So, what you should do Ipsen's method says that systematically eliminate dimensions that is all it says which means this eliminate we have got mass length and time let us say we decide to eliminate mass first.

(Refer Slide Time: 11:07)

$$F = f(L, U, \rho, \mu)$$

$$\underbrace{MLT^{-2}} \quad \underbrace{L} \quad \underbrace{LT^{-1}} \quad \underbrace{M} \quad \underbrace{ML^{-1}T^{-1}}$$

Eliminate M

$$\frac{F}{\rho} = f\left(\underbrace{L}_L, \underbrace{U}_{LT^{-1}}, 1, \underbrace{\frac{\mu}{\rho}}_{L^2T^{-1}}\right)$$

$$\frac{MLT^{-2}}{M} \quad \frac{ML^{-2}T^{-2}}{ML^{-1}T^{-1}} \quad \frac{ML^{-1}T^{-1}}{ML^{-1}T^{-1}} \quad \frac{ML^{-1}T^{-1}}{ML^{-1}T^{-1}}$$

Eliminating Mass:

$$\frac{F}{\rho} = f\left(L, U, 1, \frac{\mu}{\rho}\right)$$

$$[L^4T^{-2}] = f([L], [LT^{-1}], [1], [L^2T^{-1}])$$

So, now, this expression if you look at this expression has only length and time unit I can choose to eliminate length or time ok. So, let us say we do time first.

(Refer Slide Time: 14:15)

$$\text{Eliminate } T \text{ by dividing with } U$$

$$\frac{F}{\frac{\rho U^2}{L^2}} = f\left(\frac{L}{L}, \frac{\mu}{\rho U L}\right)$$

$$\frac{F}{\rho U^2} = f\left(\frac{\mu}{\rho U L}\right)$$

$$\pi_1 = f(\pi_2, \pi_3)$$

Eliminating time:

$$\frac{F}{\rho U^2} = f\left(L, \frac{\mu}{\rho U}\right)$$

$$[L^2] = f([L], [L])$$

So, now the entire expression only has length in it, I can now eliminate L:

$$\frac{F}{\rho U^2 L^2} = f\left(\frac{\mu}{\rho U L}\right)$$

So, the good thing is that here you do not need to solve you know the algebraic equations you do not need to really identify you know how many; you know you do not need to figure out what are the repeating variables and so on it sort of comes out naturally yeah. Huh. I did not understand can you explain again. Yes. No. So, j is 3. So, you will get two non dimensional variables n minus j non dimensional variables.

Oh! then you will get three non dimensional variables since see this we have. So, for example, here you have F by rho U square L square is only a function of another non dimensional variable right. So, similarly if you have 3 of them you will find pi 1 is a function of pi 2 comma pi 3 you do not know what f is, but this is the best you will be able to write.

So, originally if your problem contains six non dimensional variables; let us say let us take the same situation.

(Refer Slide Time: 18:07)

Handwritten equations and diagram on the slide:

$$\frac{F}{\rho U^2 L} = f\left(\frac{M}{\rho U L}\right)$$

$$\pi_1 = f(\pi_2, \pi_3)$$

$$F = (L, w, \rho, \mu, U)$$

$$n = 6, j = 3$$

$$\pi_1, \pi_2, \pi_3$$

The diagram shows a rectangle with length L and width w .

Let us say so, you only asked last time probably that if the shape was different. Let us say that it has a length L and let us say a width w let us say the third dimension is also w , then our F is going to be a function of L comma w comma ρ comma μ U .

So, here n is going to be 6, but in this case again j is going to be 3 ok. So, you can expect to find 3 non dimensional variables. Let us see you will find out them as π_1 , π_2 , π_3 ; then you can say that this is what the relationship going to be and so on. What would be the extra non dimension parameter that will come in this case can anybody guess? It'll be just w by L everything will remaining same right you only have an extra w k. So, w by L is the extra parameter that is going to come there which is basically the aspect ratio of the body which is a non dimensional parameter. And that is so, simple in this case because we have added just something which is a dimension of length and something physical ok. So, that is fine.

So, we have now learned how again a given problem if you are familiar with the number of variables or the number of variables that could be relevant, then you can write down a simple relationship instead of investigating the dependence of each of the variables ok. So, that so now, if you look at the flow what did we do? Initially we said if we knew the relation how to non dimensionalize the variable. So, we did it using an algebraic relation, we also did how to deal with the differential equations. Then now what we have done is

we did not know anything we only knew that these are possibly the variables that are affecting and then we have written down a relation.

So, one of the crucial things that you have seen in this step is that you can write down the dimensions of any physical variable as a power law expression.

(Refer Slide Time: 20:43)

Power law expression

Consider a variable $X = x U$ when I have chosen a unit system U
 x = magnitude of the quantity
 x = physical variable

$= x' U'$ if I select a unit system U'
 $= x'' U''$ if I select a unit system U''

$\frac{x'}{x}, \frac{x''}{x} \rightarrow$ Reduction ratios

So, I mentioned it a few classes before that we have written down the variable any variables the dimensions as a power law expression ok. So, is this always going to be the case? Can we always write the dimensions as a power law expression? And we are going to prove that yes it is possible and therefore, all the things that we have said so far we will continue to be hold for any problem that you pick up is the objective clear?

Consider a variable let us say X which I will write as $x U$ when I have chosen unit system U . So, what is that I have chosen? A unit system U in which x is some variable and this small x is therefore, the magnitude of that quantity; x is some physical variable, but x some let us like f is equal to 10 Newton force is equal to 10 Newton that is all what I have written, but in a general form or I could write this as x' U' if I select a unit system U' or x'' U'' if I select a unit system U'' .

So, what I am saying maybe I will take my SI system or CGS system or MKS system I could always write it right. So, for example if its length I can write it as 1 meter 100 centimeter anything that I like. So, that is what I have written now and we know that all

this should be related right all these will be related by some factors. For example, x prime by x will be some number right x prime is the magnitude in a unit system x double x is a magnitude in some other unit system and they will be related by some number.

$$X = xU$$

$$X = x'U'$$

$$X = x''U''$$

So, similarly x double prime by x for example. These are called reduction ratios. Reduction ratios are nothing, but the numbers that you need to multiply when you are moving from 1 system of units to another system of units.

$$\frac{x'}{x}, \frac{x''}{x} \rightarrow \text{reduction ratios}$$

(Refer Slide Time: 24:07)

Let r_l^1, r_m^1, r_t^1 be the reduction ratios for length, mass and time

$$\frac{x^1}{x} = f(r_l^1, r_m^1, r_t^1) \quad \text{--- (1)}$$

Similarly

$$\frac{x^{11}}{x} = f(r_l^{11}, r_m^{11}, r_t^{11}) \quad \text{--- (2)}$$

$$\frac{(1)}{(2)} \quad \frac{x^1}{x^{11}} = \frac{f(r_l^1, r_m^1, r_t^1)}{f(r_l^{11}, r_m^{11}, r_t^{11})}$$

$$r_l^1, r_m^1, r_t^1 \rightarrow \text{reduction ratios for length, mass and time}$$

So, when I define my x I did not say what it is its some variable some physical variable this vector and you know r_l^1 prime is for example, the reduction ratio for the length k . When I am changing from oh unit system U prime to unit system U what is the what is the number that I should be multiplying with that is r_l^1 prime. If it is I am talking about length or if it is mass, let it let us call it r_m^1 prime if it is time let us call it r_t^1 prime ok.

Similarly, so, within I know that I can write x' by x is going to be sum function of r_l' , r_m' , r_t' ok. So, the reduction ratio for length reduction ratio of mass reduction ratio of time each of them if I combined in some form I should be able to get the reduction ratio for any other quantity that I am dealing with remember I am only worried about 3 dimensions now 3 particular mass length and time only. As you expand the problem you could have other things coming into the picture.

Similarly I could write

$$\frac{x'}{x} = f(r_l', r_m', r_t')$$

$$\frac{x''}{x} = f(r_l'', r_m'', r_t'')$$

$$\frac{x''}{x'} = \frac{f(r_l'', r_m'', r_t'')}{f(r_l', r_m', r_t')}$$

(Refer Slide Time: 27:01)

$$\frac{x''}{x'} = \frac{f(r_l'', r_m'', r_t'')}{f(r_l', r_m', r_t')} = f\left(\frac{r_l''}{r_l'}, \frac{r_m''}{r_m'}, \frac{r_t''}{r_t'}\right)$$

Quantities $\frac{r_l''}{r_l'}, \frac{r_m''}{r_m'}, \frac{r_t''}{r_t'}$ Reduction ratios when we go from U' to U''

Fix U' , and change U'' arbitrarily
Partial derivative of (3) w.r. to r_l''

Now,

$$\frac{x''}{x'} = \frac{f(r_l'', r_m'', r_t'')}{f(r_l', r_m', r_t')} = f\left(\frac{r_l''}{r_l'}, \frac{r_m''}{r_m'}, \frac{r_t''}{r_t'}\right)$$

So, what have I written really? See if you look at the right hand side I take the reduction ratio for length mass and time separately and combine them or if I if you look at the expression in the in the middle this part I calculate the quantity in 2 different units and then take the ratio then I am going to get the same thing. For example, if I am talking about force I calculate. So, this part let us say the double prime is I have calculated it in some units let us say mass into acceleration I have done let us say I have done it as kilograms times meter per second square or this quantity the one in the denominator I will do it in CGS unit let us say I will do grams per grams in 2 centimeter per second square if I do the force ratio or I do the mass ratio and acceleration ratio and multiply them the answers are going to be same.

Essentially this part is just that fact that whether I do the forces and take the ratio or if I take the each of the components mass, length and time separately and then take the ratio and do combine appropriately I am going to get the same expression your same ratio same number that is what we have any doubts? What we will do is we will fix U double prime and change U prime arbitrarily. So, so far I talked about fixing an SI system and saying that one of the system I am going to fix the other 1 I am going to consider to be a variable so, that I can do differentiation and integrations and so, on.

So, I will say that in this quantity in this box expression, I am going to keep my double primed variables as fixed quantities and my primed variables as really variables so, that I can do differentiation. In fact, what I want to do is I want to take partial derivative of let us call this expression 3 with respect to let us say r_l prime ok. So, I am keeping my primed variables as variable really. So, if I differentiate it. So, they will do the other way I will keep the U prime I will keep U prime as the variable as the fixed quantity and U double prime as arbitrary so, that I can differentiate the primed variable. So, you could do it either way you will see that its symbols another.

$$\frac{\frac{\partial f}{\partial r_l''}(r_l'', r_m'', r_t'')}{f(r_l', r_m', r_t')} = \frac{\frac{\partial f}{\partial r_l''}\left(\frac{r_l''}{r_l'}, \frac{r_m''}{r_m'}, \frac{r_t''}{r_t'}\right)}{r_l'}$$

(Refer Slide Time: 32:21)

Partial derivative of (3) w.r. to r_l

$$\frac{\frac{\partial f}{\partial r_l''}(r_l'', r_m'', r_t'')}{f(r_l'', r_m'', r_t'')} = \frac{\frac{\partial f}{\partial r_l''}\left(\frac{r_l''}{r_l'}, \frac{r_m''}{r_l'}, \frac{r_t''}{r_l'}\right)}{r_l'}$$

Let r_l'' approach r_l'
 r_m'' " r_m'
 r_t'' " r_t'

$$\frac{\frac{\partial f}{\partial r_l'}(r_l', r_m', r_t')}{f(r_l', r_m', r_t')} = \frac{\boxed{\frac{\partial f}{\partial r_l'}(1, 1, 1)}}{r_l'} \propto$$

Now, having done that, let r_l double prime approach r_l prime ok. $r_l'' \rightarrow r_l'$

$$\frac{\frac{\partial f}{\partial r_l'}(r_l', r_m', r_t')}{f(r_l', r_m', r_t')} = \frac{\frac{\partial f}{\partial r_l'}(1, 1, 1)}{r_l'}$$

I will just call that alpha for the convenience also this is really a function of primed variables I will just drop the primes.

(Refer Slide Time: 36:01)

Dropping 's

$$\frac{\frac{\partial f}{\partial r_l}(r_l, r_m, r_t)}{f(r_l, r_m, r_t)} = \frac{\alpha}{r_l}$$

Integrate this eqn

$$\int \frac{df(r_l, r_m, r_t)}{f(r_l, r_m, r_t)} = \int \alpha \frac{dr_l}{r_l}$$

$$\frac{\frac{\partial f}{\partial r_l}(r_l, r_m, r_t)}{f(r_l, r_m, r_t)} = \frac{\alpha}{r_l}$$

Now, I am going to integrate this quantity

$$\int \frac{df(r_l, r_m, r_t)}{f(r_l, r_m, r_t)} = \int \frac{\alpha}{r_l} dr_l$$

$$\ln f(r_l, r_m, r_t) = \alpha \ln r_l + \ln g(r_m, r_t)$$

$$f(r_l, r_m, r_t) = r_l^\alpha g(r_m, r_t)$$

$$f(r_l, r_m, r_t) = r_l^\alpha r_m^\beta r_t^\gamma$$

(Refer Slide Time: 37:41)

$$\ln f(r_l, r_m, r_t) = \alpha \ln r_l + \ln g(r_m, r_t)$$

$$f(r_l, r_m, r_t) = r_l^\alpha g(r_m, r_t)$$

$$= r_l^\alpha r_m^\beta r_t^\gamma \quad \leftarrow \text{Repeat the differential with } r_m, r_t \text{ etc and then perform the integration}$$

$$f(r_l, r_m, r_t) = r_l^\alpha r_m^\beta r_t^\gamma$$

$$x = x_U, x'_U, x''_U \dots \quad \frac{x'}{x}, \frac{x''}{x} \dots$$

$$[x] = L^\alpha m^\beta T^\gamma$$

You can do it and you will find that you are going there is another thing that is going to change L was just an arbitrary choice what have you really done? We found that f of $r_l r_m r_t$ some function of reduction ratios is just going to be a power law expression that is what we found. Reduction ratios are the ones which you will use when you are changing from one system of units to another system of units. We started by saying that we are going to look at a quantity x which we will write it as either x_U or $x_{\text{prime } U}$ or $x_{\text{double prime } U}$ and so, on and we said we are looking at quantities like $x_{\text{prime } U}$ by $x_{\text{double prime } U}$ by x and so, on ok.

Now, if you want your if the reduction ratios are going to be power law expressions, then the only way x can be X will X has to be having a form L to the power of α M to the power of β T to the power of γ if x has the form of L to the power of α M to the power of β T to the power of γ then only I can have my reduction ratio having you know my reduction the reduction form will basically have this power law expression right if my x had any other form not just this power law form anything else then my reduction ratio cannot be like this because the reduction ratio is by definition when I am going from one system of units to another system of units. So, any X that I choose if the dimensions do not have this form then I cannot have this form of reduction ratio.

So, now we have found that the only way you know in an arbitrary case, the reduction ratios will always have a power law expression; that means, dimensions will always be power law expressions for any physical variable that we choose and you have seen that right any system any unit that you write will always be something to the power of something its never in any other form that is what we have proven now that that has to be the case always doubts yeah. Sure here.

Oh i. So, this is. So, this was my equation right $\text{dof by } \text{dof } l'$. So, the only variable that I have is l' . So, I just drop that r primes or you could just continue writing everything and you will end up with an expression saying that f of l' m' t' prime is l' to the power α . So, there is no physical this thing there yeah. Which one. Ha l' should I go up no its general huh. Yes. Can you be bit loud?

No it cannot no because by definition it contains only length, it is like 100 it could be. So, when you are going from cgs to si l' is just 100 like that it does not contain by definition mass or time mass and time are fundamentally different dimensions. So, therefore, l' cannot be a function of m or t ; however, x prime could be I mean we wrote it as x prime by x which may which for example, could be a reduction ratio for force which means it will contain both length mass and time in it.

So, what we have done is either we write it as a combination or we write it separately that is what we did and that is what exactly that box the expression was telling this red box the expression that on the left hand on the right hand side I do it as a function of I will change all the lengths I will change all the masses I will change all the times and appropriately combine it or on the left hand side I am saying that I will take the force in 1 units I will

take the force and other units and I will take the ratio of it I will come I will get the same number go down.

So,. So, far we. So, till we got this expression we kept these two things as two different units r_l prime and r_l double prime or rather U prime and U double prime has two different units now I am saying that one system is up and when we kept one of them fixed and other changing. So, that we could do a differentiation and we are saying that there was the one which we are changing is actually approaching the 1 which we have kept fixed ok. So, therefore, each of these ratios r_l double prime by r_l prime is essentially just one number I mean its basically same quantity because U double prime and U prime are the same system of units now ok.

So, there is no reduction ratio really that is why I just wrote it as 1 1 or simply you say that I am going to say my r_l double prime is equal to r_l prime and so, on for all primed quantities and that is why its a constant and you can see that that constant is was comes out to be as a factor which says that you know the quantity is that you know that comes as powers is essentially the derivative you know with respect to that unit system that is what that power means ok.

So, you go back you revise all these things the proof is not very important the proof is there because I thought its a nice thing to do you can just learn it and more important is to learn how to do the problems we will do one more proof and that is we are going to prove the Buckingham theorem. So, we I just said that if you have n variables and j dimensions, then we will have n minus j non dimensional parameters right. So, we will again do a similar proof like that and then we will wind up this session this topic ok. I will see you tomorrow.
