**NPTEL ONLINE CERTIFICATION COURSE**

**Unit Operations of Particulate Matter**

**Lec-01**

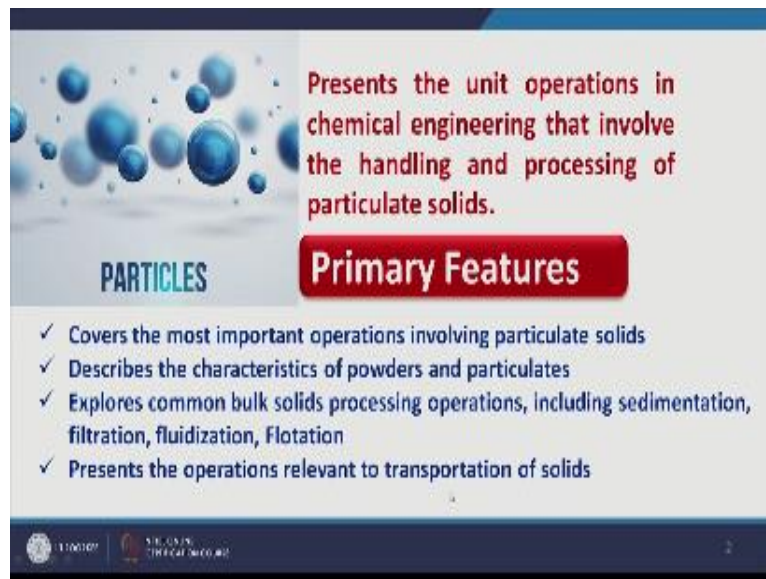

**An Introduction**

**Dr. Shabina Khanam**

**Department of Chemical Engineering  
Indian Institute of technology Roorkee**

I welcome you all in the course unit operations of particulate matter. Today we will start this course and the first lecture of this course that is the introduction. As this course is about unit operation of particulate matter.

(Refer Slide Time: 00:38)

This figure speaks about what we are going to study that is nothing but about the particles. So here I present the unit operations of particulate matters and the unit operation of particulate matter in chemical engineering, it involves the handling and processing of particulate solids. So

here as you have seen that in this particular course we are dealing with the particles, it presents the unit operations in chemical engineering that involves the handling and processing of particulate solids or particulate matter.

Now as far as this particular session or this particular course is concerned the primary features of this course is, it covers the most important operations involving particulate solids. So here basically we will discuss different unit operations which are involved to handle and process of particulate matter. It describes the characteristics of powders and particulates. Now what is the meaning of this characteristics of powders and particulates that is here as far as characteristic is concerned that we can understand in terms of size and shape of the particle as well as its density or etc.

So once we characterize the particle we will define its size, shape, density. Now in this particular course we will see the effect of size, shape and density on the particular operation we are going to discuss. The third feature is explores common bulk solids processing operations, including sedimentation, filtration, fluidization and flotation. So as far as unit operation is concerned we have covered four main unit operation that is sedimentation, filtration, fluidization and flotation.

So this particular course presents the operations relevant to the transportation of solids that is after defining, after discussing these particular unit operation, four unit operations in detail. We will discuss the operation which are involved for transportation or carrying the particle from one place to other place. When we discuss about the particle, I am discussing the bulk of particles that is the total particulate matter.

(Refer Slide Time: 03:00)

Now if you consider this particular slide, this particular slide shows what, it has different words like pharmaceutical, manufacture, crystal, droplet powder, nanoparticle from this figure you can identify what are the different application of this particular course which involve the handling and processing of particulate matter. So here we can define the unit operations of particulate matter, it deals with science and technology of solid material which is a multidisciplinary field including material science, environmental, biomedical, aerospace, agricultural, chemistry, microbiology and cell science, pharmacy and medicine.

So here you can see the course that is unit operations of particulate matter, its application is not in chemical engineering, but it is used in many other fields also. And that fields are really wide, so this particular course is useful for many fields in which engineers are the person work. Now as far as we will define further what is exactly the unit operation, before we have defined the unit operation of particulate matter it means which deals with the particulate matter. Now here we are defining the unit operation itself.

(Refer Slide Time: 04:26)

In chemical engineering and related fields, unit operation is a basic step in a process. Unit operations involve a physical change such as separation, crystallization, evaporation, filtration, sedimentation, etc. Now here if you see this statement this speaks about the physical change in the process. So here I have to clarify that unit operations deals with the physical change in the process not the chemical change, chemical change what I mean with the chemical change is when any reaction is carrying out in the process. I am not we are not going to discuss the reaction which is careering out but the physical change.

(Refer Slide Time: 05:09)

## Unit Operations – Definition

In chemical engineering and related fields, a unit operation is a basic step in a process. Unit operations involve a physical change such as separation, crystallization, evaporation, filtration, sedimentation, etc.

For example, in milk processing, homogenization, pasteurization, chilling, and packaging are each unit operations which are connected to each other to form the overall process. A process may require many unit operations to obtain the desired product from the raw materials.

When we consider the example of crystallization what happens here is the super saturated solution converts into the solid particle solid matter what is what happens over there that there we have only the physical form of the component physical form of the content will change initially it was at super saturation liquid at that stage and now it is in the solid state, so that is nothing but the physical change in the process, so that therefore this type of process or this type of operation we called as unit operation.

Where reaction is not involved and similarly in evaporation what happens water vapor water or let us say not only a water the solvent realizes from the slurries the solution so that is nothing but from convergent of from solution state convergent from liquid state to vapor state so that is nothing but the physical change, so all physical changes are involved in chemical engineering and that are clubbed in one section and that section is called unit operations.

So when we consider a particular operation it has many unit operations for examples if I am considering milk processing it as homogenization, pasteurization, chilling and packaging so these are different unit operations which are involved in manufacturing of milk and a process may require many unit operation to obtain the desired product from the raw material.

So you can see in any process there are many unit operations involved however these unit operation does not consider the reaction when we consider the reaction in any process we call as unit process not has unit operation, now that here we have here we have already defined the unit operations now before starting this the details of the unit operation of particulate matter we have to see the history where we are actually identified the unit operations in literature.

(Refer Slide Time: 07:32)

**Unit Operations – The History**

Arthur D. Little used the concept of "unit operations" to explain industrial chemistry processes in 1916 [1].

In 1923, William H. Walker, Warren K. Lewis and William H. McAdams wrote the book *The Principles of Chemical Engineering* and explained that the variety of chemical industries have processes which follow the same physical laws [2]. They summed up these similar processes into unit operations.

Each unit operation follows the same physical laws and may be used in all relevant chemical industries.

2015-11-15 10:11:11 AM UTC-0500 Walker, Lewis, and McAdams, "The Principles of Chemical Engineering," New York: McGraw-Hill, 1923.

So as far as history is considered Arthur D. Little use the concept of unit operations to explain industrial chemistry processes in 1916 so here you say the first literature about unit operation we have got in 1916 where the unit operation is used at industrial level now further in 1923 William H Walker, Warren K. Lewis and William H McAdams wrote the book the principle of chemical engineering and explain that the variety of chemical industries have processes which follow same physical laws they summed up these similar processes into unit operation.

So here we again have seen the physical law which are applicable to the process and they are clubbed in one word or one section that we can refer as unit operations so here we have some literature where the unit operation is actually used in actually appear first time now each unit

operation follows same physical law and may be used in all relevant chemical industries for example here we have seen the same physical laws will be applicable to the relevant chemical industries.

Now what is the meaning of this for example if I am going to design a mixture which mixes two component or may be 3 component together, so when we are designing a mixture whether we design the mixture for a lab scale or for a industry or for 1 process or for other process this design will follow same physical law it means the design equation will be same only scale up.

And the other condition will be applicable mostly the physical law will be same when we are going to design a picture different conditions for different application is should say like when we are going for laboratory when we are going to design this for industry, so in this here we have defined the history which is appear in the literature, now it is basically the reported history now once we see this in our day to day life you can understand that from how long they are using the concept of unit operation in our day to day life to illustrate that I have taken the example.

(Refer Slide Time: 10:12)

Here in this particular slide you can see this figure now this figure speaks about powder technology in ancient Egypt illustrating the threshing process now if you consider this particular figure here persons are involved in threshing process now what is threshing process, threshing process is basically to remove the edible material from the waste like when we remove the serials from the it is scaly waste that we also called as husk so that we can remove so if you consider this particular figure the person who is standing over here.

He has some screening tools through which the edible serial will be collected and the waste scale material that we also called as husk that is quite lighting comparison to the serials so that can be screened from this and due to the effect of wind it will be collected away from the serial so serial will be collected from one side another side we have the collection of husk so the person which are these two person which are at slightly bending position they are basically collecting the serials as well as husk separately.

So if you consider this particular picture this is taking from this is basically a wall pending in the tomb of Menna. So this is very old picture now this picture is speaks about that it is as old as mankind.

(Refer Slide Time: 11:50)

## Unit Operations – The History

It is as old as mankind and has been used in a broad field industrial activities such as food preparation, ceramics, glass and building technology. Some people consider Particle technology as the second oldest profession of mankind.

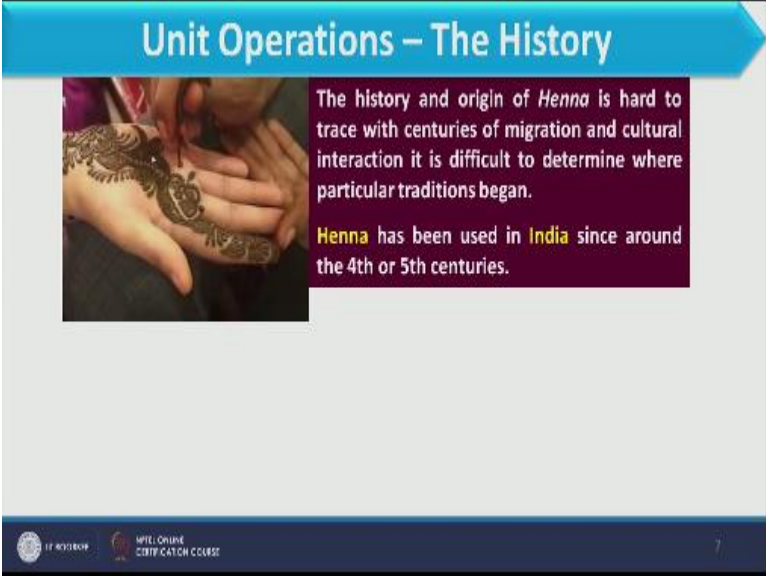

"Powder Technology" in ancient Egypt illustrating the "threshing process". Picture from a wall painting in the tomb of Menna.

MIT ONLINE CERTIFICATION COURSE

And has been used in a brought field industrial activities such as food preparation ceramics glass and building technology some people consider particle technology as a second oldest profession of the mankind so you can see over here that this particular unit operation is used since very beginning where we were aware with this or not but we were using this concept since many time many years on my decades now here if you see we have use the word order technology and in this particular course we are introducing unit operation.

So that is nothing but the synonyms of unit operation other synonyms are particle technology particulate engineering mechanical operations all these are synonyms of the unit operations so when I speak about particle technology powder technology mechanical operation and doing nothing but I am speaking about unit operation itself. No let us consider few more example from the history if you consider this particular figure that you understand very well.

(Refer Slide Time: 13:00)

The slide features a blue header with the title "Unit Operations – The History". Below the header, on the left, is a photograph of a person's hand with intricate henna designs. To the right of the photo is a purple text box containing the following text: "The history and origin of *Henna* is hard to trace with centuries of migration and cultural interaction it is difficult to determine where particular traditions began. *Henna* has been used in *India* since around the 4th or 5th centuries." At the bottom of the slide, there is a dark blue footer with logos for "IIT Kharagpur" and "NPTEL ONLINE CERTIFICATION COURSE", and a small number "7" on the right.

This is nothing the Henna we also call it maybe now if you see this figure here what happens how this ammonia or Henna is prepared if you see this initially we collect the Henna leaves and then that these leaves will be crushed and crush to the very fine size and then it is mixed with the water to make the paste now when we are crushing this so what we are doing basically is we are involving unit operation in this because that is nothing but the physical change that is from higher particle size.

That is in terms of leaf we are converting this into the lower particle size that is a powder so here we have involvement of unit operation now the history and origin of Henna is hard to trace with centuries of migration and cultural interaction it is difficult to determine where particular traditions began so you can understand this from how long we are using Henna that we all we are not aware but Henna has been used.

(Refer Slide Time: 14:05)

## Unit Operations – The History

The history and origin of *Henna* is hard to trace with centuries of migration and cultural interaction it is difficult to determine where particular traditions began.

*Henna* has been used in *India* since around the 4th or 5th centuries.

As back as 3000BC in India Turmeric Powder, Spices Powder and Ayurvedic Medicine made up of powders (using particle technology) were used.

7

India since around the 4<sup>th</sup> and 5<sup>th</sup> centuries so this is a quite old data so you can understand from how long we are using now this particular figure it speaks about different spices so as back as 3000BC India turmeric powder a species powder and Ayurvedic medicine made up powders using particle technology were used so since very beginning we are using this unit operation in our day to day life. Whether we were aware with that or not but we were using it now here you see this particular figure.

(Refer Slide Time: 14:50)

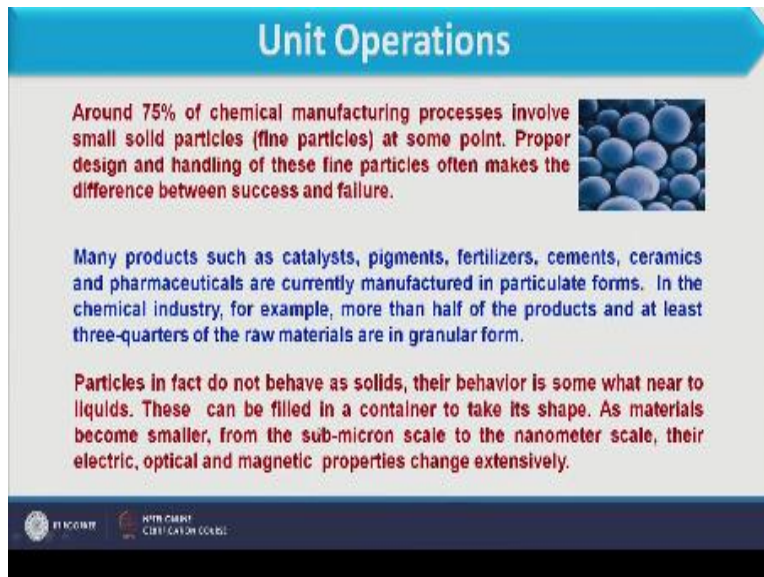

What is this, this I think we all are aware with this, this is nothing but we use this for to prepare the species in our houses even I have seen this in my house since my childhood and you all have seen so this is nothing but we can say an arrangement we can say and equipment which involve unit operation to convert the size higher size particle to lower size so that is nothing but the physical change so we can say that it can be a unit operation.

So here this is basically Indian stone grinder in the second figure in this figure weird the if the shape is quite oval type this is Sudanese stone grinder, so the old traditional method of grinding the grains in India and Africa which was widely used until 20<sup>th</sup> century was crushing then by stones so here you see 20<sup>th</sup> century data is available over here and since many time back from this we are using this stones to crush the material.

So here you can say that we are using unit operations since many decades however in 1916 it appears first in the literature as far as industrial application is concerned. So that was about the history of unit operations till now you can understand.

(Refer Slide Time: 16:24)

**Unit Operations**

Around 75% of chemical manufacturing processes involve small solid particles (fine particles) at some point. Proper design and handling of these fine particles often makes the difference between success and failure.

Many products such as catalysts, pigments, fertilizers, cements, ceramics and pharmaceuticals are currently manufactured in particulate forms. In the chemical industry, for example, more than half of the products and at least three-quarters of the raw materials are in granular form.

Particles in fact do not behave as solids, their behavior is somewhat near to liquids. These can be filled in a container to take its shape. As materials become smaller, from the sub-micron scale to the nanometer scale, their electric, optical and magnetic properties change extensively.

ETN COINTE  
HYDROCARBON  
CERTIFICATION COURSE

Basic operation is basically the physical change and unit operation basically involved the particle it matter or solid, now why we are defining this course that is unit operation of particle it matter, particle it matter why we are considering because you all are aware that around 75% of chemical manufacturing processes involve a small solid particle at some point, so we have used the particles in our day to day life and as far as chemical processes are concerned they also use this extensively so proper design and handling of these fine particle often makes the difference between success and failure of the product.

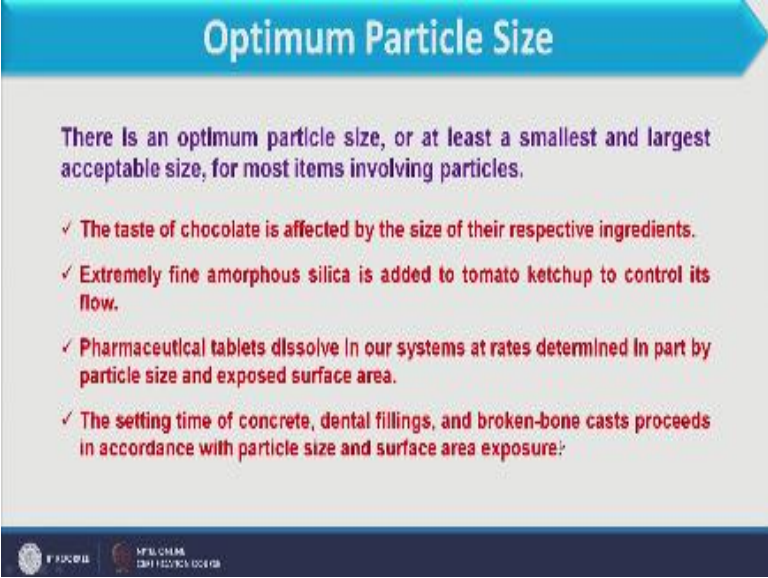

Now why I am calling this success and failure of the product depend on the particle size to illustrate that I will give a few examples in subsequent slide. Now as far particle it matter is concerned it prepares different products such as catalyst, pigments, fertilizers, cements, ceramics and pharmaceuticals they are currently manufactured with the particle it forms so in chemical industry for example more than half of the products and atleast three quarters off the raw material are in granular form.

So here you can understand the particular matter they are consider in industrial scales significantly. Now further if we consider the particle that can have a definite shape but we are

considering the number of particles so particles in fact do not behave as solids their behavior is somewhat near to liquid, how we can say that because when we consider different when we consider a number of particle size in a glass and when we tilt the glass it will be tilted so it can take the shape of the container and it can change its property as the property of liquid changes, so therefore we can resemble the behavior of this with the liquid, so as material become smaller from sub micron scale to a nano scale their electric optical and magnetic properties change extensively.

So what is the meaning of this, that when we consider different particle size their property changes and therefore it behaves differently when we consider different particle size and therefore it's the failure and success of the product depends on the particle size because it changes the property of the material. Now far as optimum particle size is concerned.

(Refer Slide Time: 19:12)

### Optimum Particle Size

There is an optimum particle size, or at least a smallest and largest acceptable size, for most items involving particles.

- ✓ The taste of chocolate is affected by the size of their respective ingredients.
- ✓ Extremely fine amorphous silica is added to tomato ketchup to control its flow.
- ✓ Pharmaceutical tablets dissolve in our systems at rates determined in part by particle size and exposed surface area.
- ✓ The setting time of concrete, dental fillings, and broken-bone casts proceeds in accordance with particle size and surface area exposure.

At the bottom of the slide, there are two logos: the first is a circular logo with Chinese characters, and the second is a rectangular logo with the text 'MATERIALS' and '130114221001001001'.

There is an optimum particle size or at least a smallest and largest acceptable size for most items involving particles, a few examples I am considering over here the first is the taste of chocolate is affected by the size of their respective ingredients to illustrate that I will speak about the particle size of chocolate in a subsequent slide so you can have the idea how the taste changes, secondly

extremely fine amorphous silica is added to tomato ketchup to control its flow, so here you can understand the extremely fine silica we add.

So that is nothing but the a very small particle size or that optimum particle size which controls the flow of the ketchup and similarly pharmaceuticals tablets dissolve in our system at rates determined in part by particle size and exposed surface area. Now to give an example of this if we purchase the crosin that is very common tablet if we purchase the crosin and consume this even I have experience this many a time that some time the crosin reduces the temperature and some time it does not affect.

So what is the reason of this because composition of crosin is same, company same so what is the difference, difference is the particle size they are considering, they consider not the optimum particle size which considers which takes the optimum time or which takes minimum time to react, so here we can see the effect of particle size even the tablets which I think most of us consume and finally we have the settling time of concrete, dental filling and broken bone casts proceeds in accordance with the particle size and surface area exposure. So this will depend upon the particle size optimum particle size basically.

(Refer Slide Time: 21:18)

Range of particle diameters in different products			
Particle size	Product	Particle size	Product
8.83 $\mu\text{m}$	Chocolate Powder	710-3350 $\mu\text{m}$	Coffee Powder
30-80 $\mu\text{m}$	Spray Dried Milk	30-50 $\mu\text{m}$	Coarse paint powders
150-450 $\mu\text{m}$	Sugar Caster	10-20 $\mu\text{m}$	Ultrafine powder paint
200-600 $\mu\text{m}$	Extra Fine Sugar	0.005-1.0 $\mu\text{m}$	Acrylic Paint
650-900 $\mu\text{m}$	Crystal 750 Sugar	10 $\mu\text{m}$	Talcum Powder
800-2200 $\mu\text{m}$	Coarse Sugar	1 $\mu\text{m}$	Wood smoke particles

Particle size analysis shows guidance to the chocolate producers in their efforts to make the best consumer-acceptable product. The control of chocolate viscosity is vital to its quality and production cost and is directly influenced by solid particle size distribution (PSD). The taste test results ranked the chocolate with the finest size distribution as having the best taste and "mouth feel".

So here if we consider in this slide there we have the range of particle diameters in different product like if we consider the chocolate powder the optimum particle size is 8.83 micrometer and similarly for other material. Now if you consider the particle size of chocolate powder what we have this like optimum particle size the taste of chocolate is affected by the particle size as we have seen in the last slide.

Now why we are saying that because when we consider a smaller particle size it basically controls the viscosity when it you can understand when it we are considering very fine particle size it behaves as a liquid, so when the particle size is very small it is a viscosity is controlled in such a way so that it is spreads in the mouth and give the mouth feel. So based on that we can say that the chocolate is having a mouth feel or not and accordingly we have different taste.

If to give an example, if we consider the chocolate of very fine particle size and we have the mouth feel these days we have experienced mouth feel in different biscuits also. For example, if I take the biscuit that very famous biscuit and that we call as dark fantasy if you consider that biscuit and when we break this when we have this then it has liquor inside this, so that liquor is basically the very fine particle size chocolate.

And when we consume this it gives the mouth feel the coating of the biscuit will not give the mouth feel only the chocolate which is inside so that is, that has a particular optimum size and that optimum size gives the mouth feel so therefore the particle size will be depending upon whether the product is acceptable by the consumers or not. For example, dark fantasy if we consider that we like a lot because of the mouth feel and similarly the chocolate when we consider it also has the mouth feel and sometimes we have seen in TV the advertisement like chocolate come in thumb bomb we call at.

So that bomb is nothing but when we have the mouth feel of chocolate and that we can find through very fine particle size. So here you can say the particle size will depend upon whether product is acceptable by the consumers or not or in other word whether the product is successful or not. So the previous slide statement if you remember that we have seen the particle size affects the success and failure of the product and this one example of that.

(Refer Slide Time: 24:30)

Now another example here we are considering the wheat we all consume wheat, now if you consider this particular figure here this figure shows the wheat the raw wheat or we call it at the

serials. Now if consider one particle size this particle size maybe of length by 5mm, 6mm or sometime 4mm also when we consider this when we consume this wheat it will not be easily digestible because of its size, in this figure we have another product from the same source that is the wheat we called this as the dahlia that is nothing this dahlia is nothing but the small smaller size of this wheat and you can understand that when we have this smaller size wheat it is healthy food because of this particle size because it considers the fibers protein etc.

This also considers fibers, protein but due it size it cannot be it cannot be taken directly so we reduce this size of the particle wheat to make the dahlia. Another product of the wheat is semolina we also call it shoji so that you can understand that is nothing but the product of the wheat of different it has a smaller particle size than dahlia it will be used in making pastas etc, and that is also very healthy food.

Now further when we consider the product of wheat that is we all are aware with this that is nothing but the Atta that we use in our daily life and that is also contains fiber protein carbohydrate etc so that is again the healthy food and finally we have the product that we called as Maida, so that is very fine particle but it is developed it is prepare with the wheat itself, so it is basically just a carbohydrate content of the wheat and it is free from vitamin, fiber and protein.

So you see this even we consider this Maida it has very less particles size so that fiber vitamin all are remove from this only carbohydrate is remaining. So therefore this is not healthy food as for as our consumption is concerned but we have this in different product so you can understand that from this wheat we have derived four different products that is dahlia shoji Atta and Maida. So all three are healthy but Maida is not healthy so that depend on the particle size of a particular product of a particular material in which particle size we are consuming so that it can help us.

(Refer Slide Time: 27:24)

Industries that uses Particulate Matter		
Coal Chemicals	Explosives	Phosphorous Production
Ceramics	Paints	Food and Beverages
Potassium Production	Glass Industry	Plastics
Synthetic Fibers	Nuclear Industry	Biomedical
Fertilizer	Pharmaceuticals	Aerospace

And here we have different industries which are using particulate matter, so these are coal chemicals, ceramic, potassium production, synthetic fibers, fertilizers, explosives, paints, glass industry, and many more. So you can understand this particular course is applicable to many industries. Now further we consider the unit operations.

(Refer Slide Time: 27:47)

What are the different unit operations available, so in chemical engineering chemical unit operation consist total five categories or five classes the first class is the fluid flow processes it include fluid transportations, filtration, and solid fluidization. Second class is the heat transfer processes it involves evaporation and heat exchange. Third category mass transfer processes it considers absorption, distillation, extraction, adsorption and drying these are different unit operation which are involve in the mass transfer processes.

Now forth category we have is the thermo dynamic processes it includes gas liquefaction and refrigeration the fifth category is the mechanical processes which consider solid transportation, crushing and pulverization and screening. Now among this five category in this particular course we will speak about the fluid flow processes as for as well as the mechanical processes, in fluid flow processes we consider filtration fluidization sedimentation and flotation that is the fluid flow processes.

And in mechanical processes we will discuss the solid transportation, so this two unit operations are involved in this particular course. Now for this particular course the target audience would be the under graduate students.

(Refer Slide Time: 29:28)

The slide features a blue header with the title 'Unit operations of Particulate Matter'. Below it, a red arrow-shaped box contains the text 'Target Audience'. The main content area is light gray and contains two paragraphs of text. At the bottom, there is a dark blue footer with two logos: the UGC logo on the left and the NPTEL logo on the right.

## Unit operations of Particulate Matter

### Target Audience

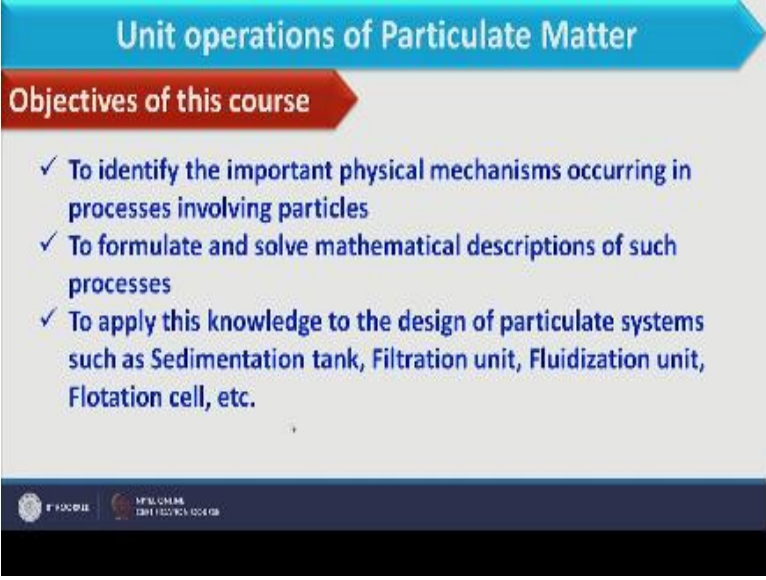

Undergraduate students.

However, this course will also be helpful for anyone of any professional level, preferably holding a college degree or with substantial industrial experience, working in the production, handling, processing, modification and transportation of particulate matter.

UGC  
NPTEL

However this course will also be helpful for anyone of any professional level, preferably he or she should have the college degree or substantial experience industrial experience who can work or who can has already work in the production handling processing modification and transportation of particulate matter. So all persons who are involved in this they can join this course.

(Refer Slide Time: 30:03)

The slide features a blue header with the title 'Unit operations of Particulate Matter'. Below it, a red arrow-shaped box contains the text 'Objectives of this course'. The main content area is light gray and lists three objectives, each preceded by a blue checkmark. At the bottom, there is a dark blue footer bar containing two logos and their respective names: 'FACULTY' and 'NIPUN CHINA'.

## Unit operations of Particulate Matter

### Objectives of this course

- ✓ To identify the important physical mechanisms occurring in processes involving particles
- ✓ To formulate and solve mathematical descriptions of such processes
- ✓ To apply this knowledge to the design of particulate systems such as Sedimentation tank, Filtration unit, Fluidization unit, Flotation cell, etc.

FACULTY NIPUN CHINA

Objective of this course is to identify the important physical mechanism occurring in the processes involving particles to formulate and solve mathematical descriptions of such processes. To apply this knowledge to the design of particular systems such as sedimentation tank, filtration unit, floatation cell, etc. so these are the different objectives of this particular course. Now this particular course basically covers sedimentation you can see

(Refer Slide Time: 30:35)

From this diagram if we need to collect the thick sledge as well as the clarified liquid and clarified solvent so we can go for the sedimentation process.

(Refer Slide Time: 30:48)

Second is the sedimentation process is the filtration we all are aware with that we have the filter media and the particles which are falling in this if it has the larger particles size then the opening it will be blocked otherwise the next rest will be passed through the media so that is nothing but the filtration. We all have use the filtration in our labs when we have the funnel, when we have the filter paper when we have the test tube. So here this particular figure shows the filtration at laboratory scale.

(Refer Slide Time: 31:31)

Another topic is fluidization where the solid particles are fluidized with help of air and liquid. Fluidized means they will be considering the flowing they will be transported flowing state from the static state. Further we will consider the flotation this particular figure I have only shown to give you

(Refer Slide Time: 31:56)

Unit operations Covered in this Course

**Flotation**

<https://www.britannica.com/technology/Flotation-ore-dressing>  
<https://gabrielmichaelvga.wordpress.com/2011/12/05/the-physics-of-flotation/>

25

The idea what is flotation that when material floats over the surface that will call has floatation?  
Now this second figure speaks about the particular operation as far the chemical engineering is concern. So we will concede the flotation.

(Refer Slide Time: 32:16)

And then we will finally consider the transportation of particulate matter that is how that the solid material is transported from one part to another part in plant as well as away from the plant also.

(Refer Slide Time: 32:32)

Here we have some of the references which we references in terms of books the books which we are going to refer this particular course these are 5 books other thing we have also considered some web page at sectors so that I will when speak it will appear in that time. I will speak about that so these are the few references.

(Refer Slide Time: 32:58)

So here we have the video the course unit operation of particulate matter is defined along with it is industrial applications. The importance of the course is discussed while highlighting it is utility from ancient time to present days. The effect of particle size on product quality was discussed. Unit operations covered in this course was briefed.

So here this is the first lecture where you have idea what unit operation particulate matter what is it is application what was it is history and what is it utility in our day to life. So I think you have enough idea this introductory class that why are you going to study this course. It has utility to day to day life at industrial scale also. So that is all from now. Thank you.
