

Chemical Process Safety
Professor Shishir Sinha
Department of Chemical Engineering
Indian Institute of Technology Roorkee
Lecture 6
Toxicology
Introduction, Routes and Exposure

Welcome to the toxicological studies module and toxicology is one of the most dangerous thing in the process industries apart from fire and explosion. Now it is not only possess the immediate danger but sometimes its affects you may observe in due course of time or even in the later part of your life. So in this particular module we will deal with what is toxicity, what is toxin and how we can go ahead with the toxicological studies? What are the different routes through which any toxicant can enter your biological system? What are the exposure symptoms, et cetera.

(Refer Slide Time: 1:10)

Toxicological Studies
Significance of chemical safety

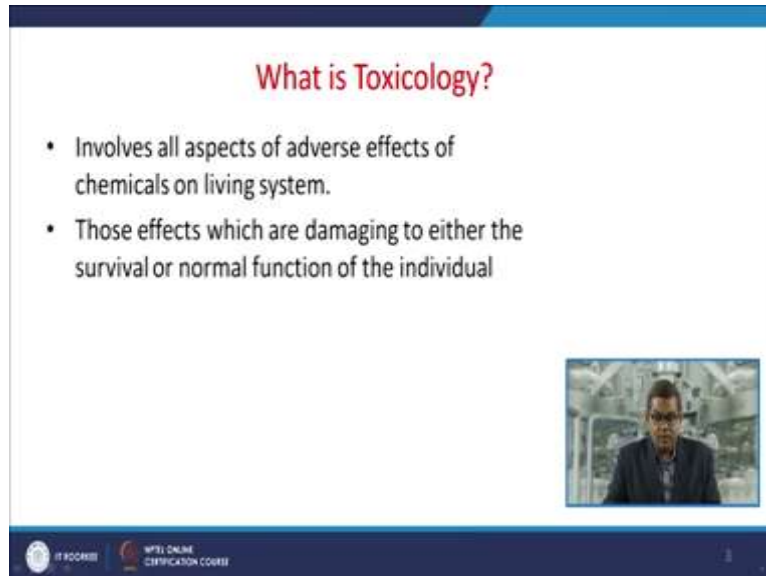

- ❖ 8.3% (Ref. 2016-17 UNO) of all deaths are due to environmental exposure to selected chemicals each year.
- ❖ Major contributors: Indoor smoke from solid fuel use, outdoor air pollution and second-hand smoke, followed by occupational particulates, chemicals involved in acute poisonings, and pesticides involved in self-poisonings.

The slide includes two images: a green 'SAFETY FIRST' sign against a blue sky with clouds, and a small video inset showing a man in a dark jacket speaking in a laboratory or industrial setting. At the bottom left, there are logos for IIT Roorkee and NPTEL Online Certification Course.

Now, this as per the United Nation organization report published in year 2016-17 almost 8.3 percent of all deaths are attributed to the environmental exposure. These exposures are attributed to the selected chemicals each year and remember do not forget the Bhopal Gas Tragedy, it is because of one of the most toxic substance Methyl isocyanate. Now major contributors to this toxicological aspect are indoor smoke from solid fuel used, outdoor air pollution and second-hand smoke, followed by the occupational particulates, chemicals involved the acute poisoning and pesticides involved in self-poisoning.

Now remember, whenever we talk about the pesticides they are intermediate during the production and even raw material causes a severe problem.

(Refer Slide Time: 2:05)

What is Toxicology?

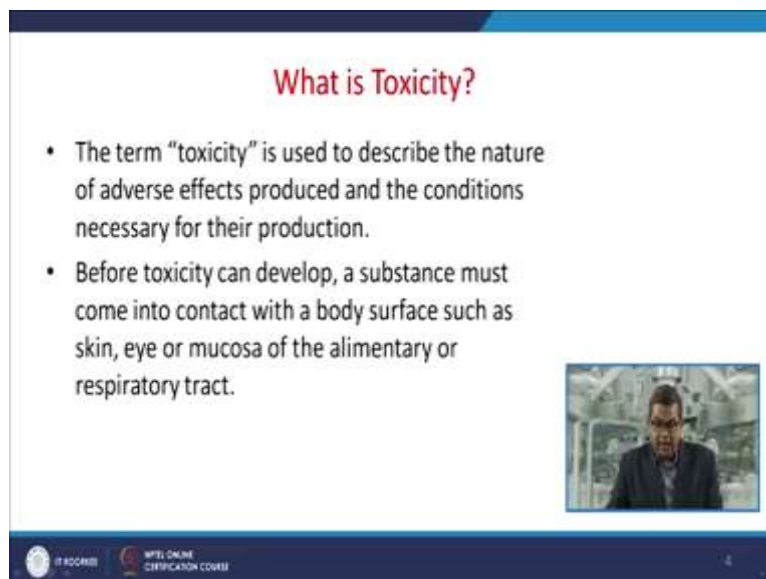

- Involves all aspects of adverse effects of chemicals on living system.
- Those effects which are damaging to either the survival or normal function of the individual

UACGRII WTEL ONLINE CERTIFICATION COURSE

The slide features a red title, two bullet points, and a small video inset of a man in a suit. At the bottom, there are logos for UACGRII and WTEL ONLINE CERTIFICATION COURSE.

Now, question arises what is toxicology? This involves all aspect of adverse effect with the chemicals on the living system. Those effects which are damaging to either the survival or normal function of individual, so this is toxicology. So whenever we study the toxicology then question arises what is toxicity?

(Refer Slide Time: 2:30)

What is Toxicity?

- The term "toxicity" is used to describe the nature of adverse effects produced and the conditions necessary for their production.
- Before toxicity can develop, a substance must come into contact with a body surface such as skin, eye or mucosa of the alimentary or respiratory tract.

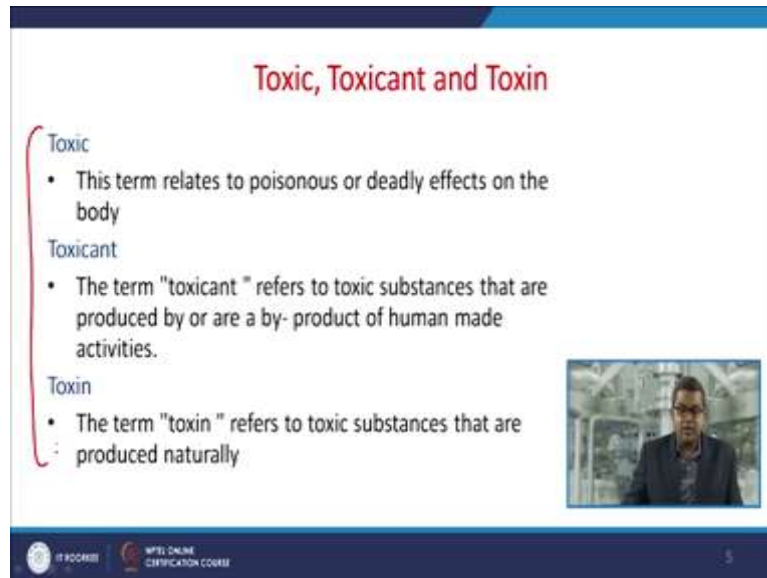

UACGRII WTEL ONLINE CERTIFICATION COURSE

The slide features a red title, two bullet points, and a small video inset of a man in a suit. At the bottom, there are logos for UACGRII and WTEL ONLINE CERTIFICATION COURSE.

So, the term toxicity is used to describe the nature of adverse effect produced and the conditions necessary for their production. So remember we will consider the process as well

as end use. Now before toxicity can develop a substance must come into contact with a body surface such as skin, eye, mucosa or any other alimentary or respiratory tract. So in this particular chapter we are going to deal with all these aspects.

(Refer Slide Time: 3:02)

Toxic, Toxicant and Toxin

Toxic

- This term relates to poisonous or deadly effects on the body

Toxicant

- The term "toxicant " refers to toxic substances that are produced by or are a by- product of human made activities.

Toxin

- The term "toxin " refers to toxic substances that are produced naturally

IT 1000331 NPTEL ONLINE CERTIFICATION COURSE

Now, before we go ahead, let us understand that what is toxic, toxicant and toxin. Now toxic substance they are available in two forms, one is the nature oriented and second is the man made toxicants. So toxic, this term relates the poisonous or deadly effect on the body. Now toxicant, this term toxicant refers to the toxic substance that are produced by or are by a by-product of human made activities. Now the term toxin refers to the toxic substance that are produced naturally. So you can clear cut remark it the three different aspect of toxicity.

(Refer Slide Time: 3:41)

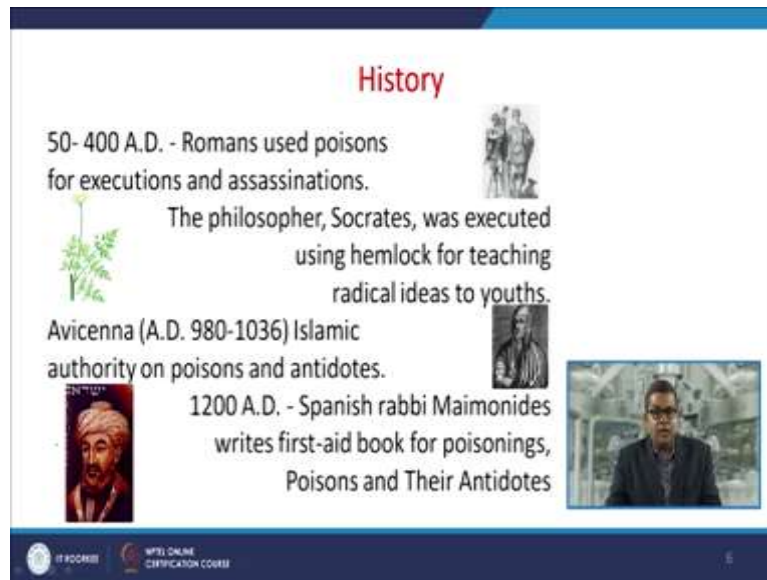

History

50- 400 A.D. - Romans used poisons for executions and assassinations.

The philosopher, Socrates, was executed using hemlock for teaching radical ideas to youths.

Avicenna (A.D. 980-1036) Islamic authority on poisons and antidotes.

1200 A.D. - Spanish rabbi Maimonides writes first-aid book for poisonings, Poisons and Their Antidotes

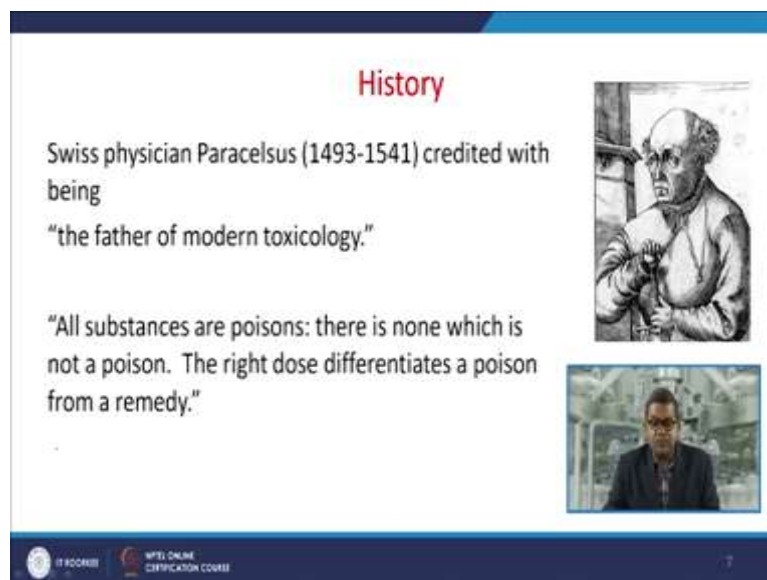

Now, if we consider the history of toxicity or toxicological studies; in between 50 to 400 AD roman used to poison for execution and assassination of their enemies. The philosopher, Socrates, was executed using the hemlock for teaching radical ideas to youths. Avicenna between 980 to 1036 AD Islamic authority on poison and antidotes. 1200 AD is Spanish rabbi Maimonides writes first-aid book for poison and poison and their antidotes because whenever we talk about the poison, whenever we talk about the toxicity, whenever we talk about the toxin then definitely must think about their remedial measures.

(Refer Slide Time: 4:32)

History

Swiss physician Paracelsus (1493-1541) credited with being “the father of modern toxicology.”

“All substances are poisons: there is none which is not a poison. The right dose differentiates a poison from a remedy.”

Now, Swiss physician Paracelsus in 1493 to 1541 credited with the being “the father of modern toxicology” because it is a science rather than the poison, it is a science. So all

substances are poison it is his verdict, there is none which is not poison. The right dose differentiate a poison from a remedy. Even water may become fatal if you take the access dose of water definitely it may become fatal and sometimes it may create a further problem.

So that is why all substances are poison and you have to find out that what is the actual dose which is required for the body system and if you take the access dose then definitely it may create a problem to your body structure as well as environment.

(Refer Slide Time: 5:28)

I would like to quote an individual view by S G Gilbert; the sensitivity of the individual differentiates a poison from a remedy. The fundamental principle of toxicology is the individual's response to a dose. Now remember whenever we talk about the individual's response that discovers the age, atmospheric condition, sex, et cetera because sometimes if you are young then you may overcome any kind of toxic exposure, but if you are a kid or if you are little bit older then definitely you may be over exposed to those kind of dose and if you go to the doctor then definitely based on these parameters they decide the actual dose of any medicine.

(Refer Slide Time: 6:11)

TOXICITY vs HAZARD/RISK
[an important distinction]

Toxicity
The ability of a substance to have an adverse effect on the health or well-being of a human
The toxicity of a chemical depends on the degree of exposure and absorption

Hazard/Risk
The probability that the concentration will occur at that site in the body

© IIT Kharagpur NPTEL ONLINE CERTIFICATION COURSE

Now, there is hairline difference between the toxicity, and hazard. The toxicity; the ability of a substance to have an adverse effect on the health or well-being of human. The toxicity of a chemical depends on the degree of exposure and absorption. However, the hazard is the probability, hazard/ Risk is the probability that a concentration will occur at the site in the body. So you need to find out that whenever you got an exposure with the toxic substance, what is the route and at which point of time and at what point of time it is going to affect your body? And what is the target organ which is being affected? So in this particular chapter, in this particular module we will discuss all these things.

(Refer Slide Time: 7:00)

TOXICITY vs HAZARD

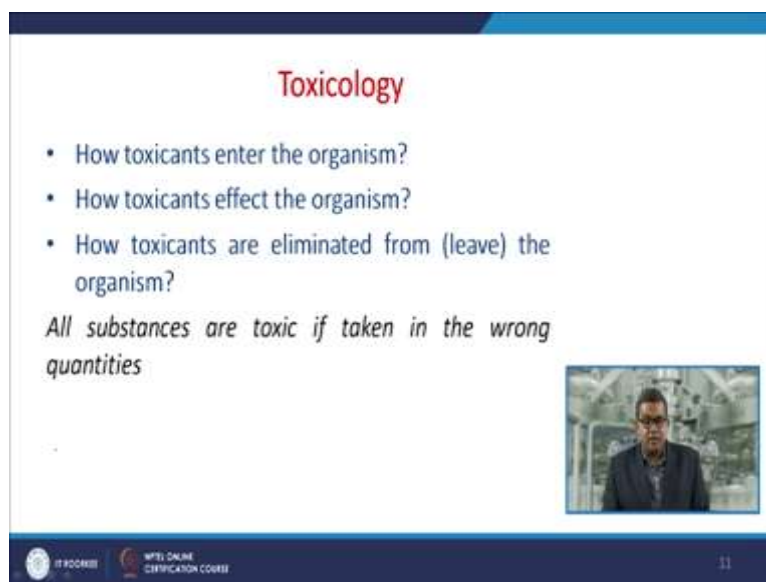

Two chemicals can possess the same degree of toxicity, but present different degrees of hazard.
Ex. Odorless and non-irritating vs. pungent odor
The chemical with warning properties may present a lesser degree of hazard.

© IIT Kharagpur NPTEL ONLINE CERTIFICATION COURSE

The two chemicals can possess the same degree of toxicity, but present in different degrees of hazard. It also attributes several other parameters like your age, weight, physical conditions, etc. The best example is odorless and non-irritating versus pungent odor. Remember nature gave you a beautiful things to determine that which one is correct and which one is not correct? So chemical with the warning properties may present the lesser degree of hazard.

(Refer Slide Time: 7:30)

Toxicology

- How toxicants enter the organism?
- How toxicants effect the organism?
- How toxicants are eliminated from (leave) the organism?

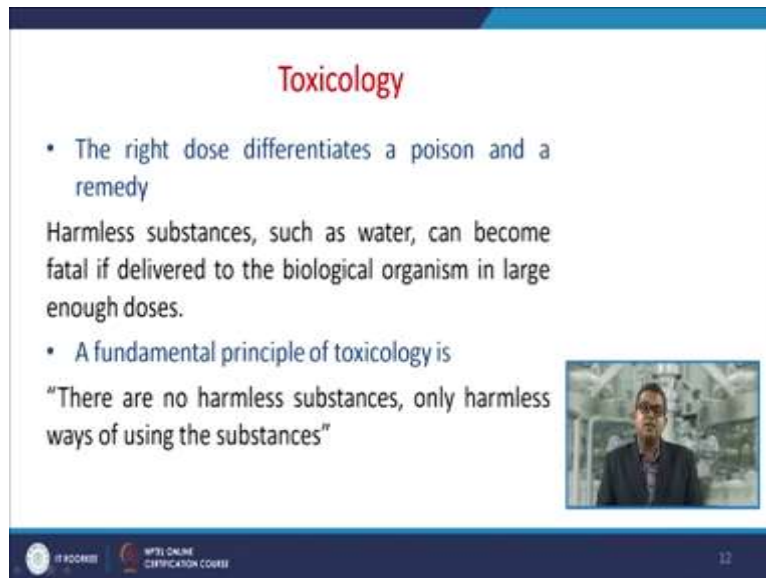

All substances are toxic if taken in the wrong quantities

WPI ONLINE CERTIFICATION COURSE 11

Now, when we go ahead with the systematic study of toxicology, we must know that how these toxicants can enter into the biological system means your human body or animal body et cetera or to the environment? Then second question must be asked that how these toxicants can affect the organism? Means whenever you are under the contamination of those toxicants then how these can affect your body system?

Now, once these two questions are answered then you must answer the things that how toxicants can be eliminate from your body system or they can leave from your body system? Now all substances, remember again; all substances are toxic if taken in a wrong quantities. So you must know that what is the dose and what is the actual response for that particular dose?

(Refer Slide Time: 8:27)

Toxicology

- The right dose differentiates a poison and a remedy

Harmless substances, such as water, can become fatal if delivered to the biological organism in large enough doses.

- A fundamental principle of toxicology is
"There are no harmless substances, only harmless ways of using the substances"

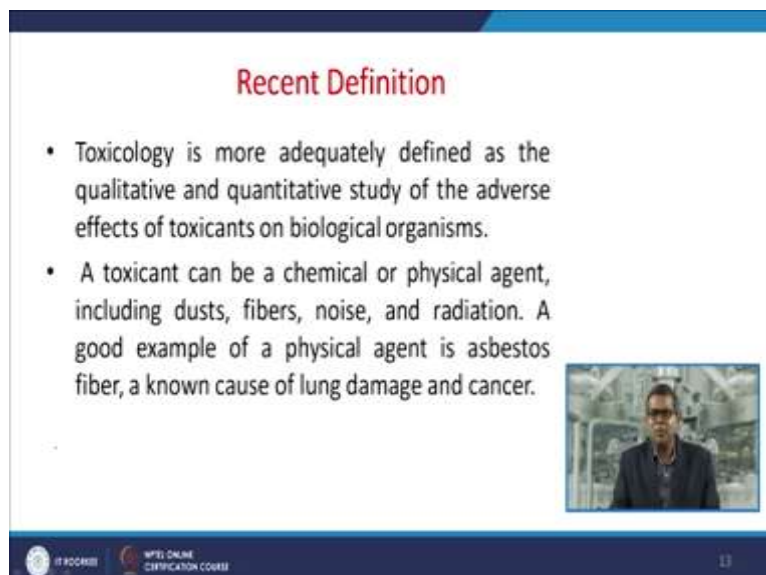

NPTEL ONLINE CERTIFICATION COURSE 12

So based on these particular aspects the right dose differentiates a poison and a remedy. It is just like that whenever we got the vaccination then a limited quantity or required quantity of that particular virus being injected into our body system. So the harmless substance such as water even becomes the fatal if delivered to the biological organ in a large kind of doses which is not required to your body system.

So the fundamental principle of toxicologies is; there are no harmless substance, only the harmless ways of using the substance.

(Refer Slide Time: 9:00)

Recent Definition

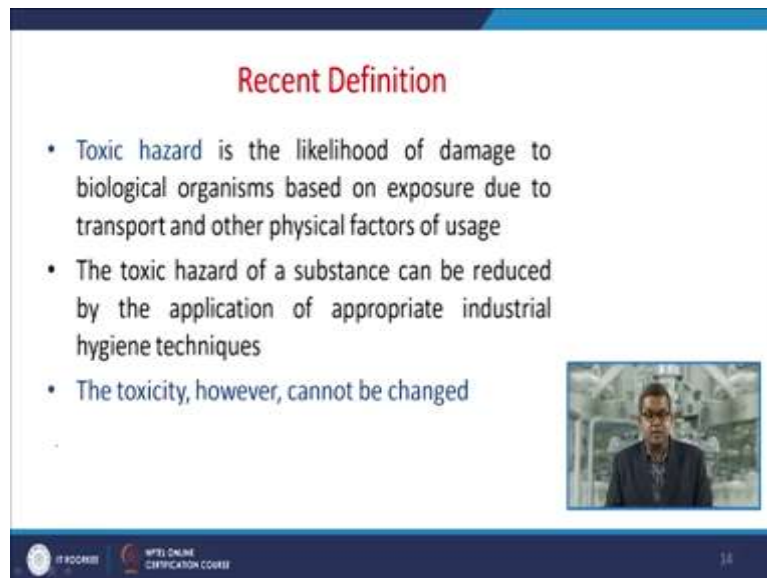

- Toxicology is more adequately defined as the qualitative and quantitative study of the adverse effects of toxicants on biological organisms.
- A toxicant can be a chemical or physical agent, including dusts, fibers, noise, and radiation. A good example of a physical agent is asbestos fiber, a known cause of lung damage and cancer.

NPTEL ONLINE CERTIFICATION COURSE 13

Now, based on all these discussion the people have predicted the most advance definition for the toxicology. Now toxicology is more adequately defined as the quantitative and quantitative study of adverse effect of toxicant on biological system. So a toxicant can be a chemical or a physical agent, including dust, fiber, noise, radiation, etc. A good example of physical agent is the asbestos fiber a known cause of lung damage and cancer.

(Refer Slide Time: 9:44)

The slide is titled "Recent Definition" in red text. It contains three bullet points: "Toxic hazard is the likelihood of damage to biological organisms based on exposure due to transport and other physical factors of usage", "The toxic hazard of a substance can be reduced by the application of appropriate industrial hygiene techniques", and "The toxicity, however, cannot be changed". A small video inset shows a man in a suit speaking. The slide footer includes the IIT Bombay logo, "IIT Bombay", "NPTEL ONLINE CERTIFICATION COURSE", and the number "34".

So government is now thinking to ban all kind of asbestos fiber, previously it is used as asbestos sheet for roofing or panelling. Now toxic hazard is the likelihood or damage to the biological system based on exposure due to the transport and other physical factor of usage. The toxic hazard of a substance can be reduced by the application of appropriate industrial hygiene technique.

So, you must create a barrier between yourself and exposure of toxic substance, but the toxicity of particular substance cannot be changed under any circumstances. So you cannot change the toxicity of methyl isocyanate, you cannot change the toxicity of arsenic. The only thing is that you must know that what is the barrier and what is the threshold limit for the intake for MIC to intake the body system.

(Refer Slide Time: 10:38)

ROUTES OF EXPOSURE

- Inhalation
- Ingestion
- Skin contact
- Injection

The slide features a red graphic of a human figure with four arrows pointing outwards from the head, mouth, skin, and injection site. A small video inset in the bottom right shows a man in a lab coat. The footer includes the IIT Bombay logo, 'NPTEL ONLINE CERTIFICATION COURSE', and the slide number '15'.

Now, there are basically 4 routes of exposure for any toxicant entry into a biological system. One is inhalation, ingestion, skin contact, and injection. Now these are the 4 prominent routes through which anything can enter into your body system.

(Refer Slide Time: 10:58)

EFFECTS OF EXPOSURE

- ACUTE - a "one-time" event
 - rapid absorption of material
 - exposure sudden & severe
 - critical period for death/survival
- CHRONIC - small doses over long time
 - rate of intake > rate of elimination
 - material remains in tissue; injures

The slide features a small video inset in the bottom right showing a man in a lab coat. The footer includes the IIT Bombay logo, 'NPTEL ONLINE CERTIFICATION COURSE', and the slide number '16'.

Now, before we go into the detail that how injection, how inhalation creates a problem we must know several other factors like acute that is the effect of exposure, the acute a one-time event that is the rapid absorption of a material and sometimes it may cross the threshold limit values, the exposure sudden and severe, the critical period for death or survival. Similarly the chronic that is a small doses versus over a long time sometimes if you are working in a workplace and where the small quantity of toxic substance being released then you may get a

very small doses, those doses of toxicant may accumulated within your body system and the effect may appear after a long time, so sometimes suppose you are working for a year or two and you are continuously bring exposed to that particular toxic and that may create a chronic problem.

So it all depends on the rate of intake, the rate of elimination it is both things are all together substitute to each other, the material remain in the tissue, injures like if the material remain in the tissue that may get deposited into the fatty tissues and when you become progressive and you are become older then all those fatty tissues may decomposed and the effect of that particular component or toxic substance may be prominent.

(Refer Slide Time: 12:18)

The slide is titled "TYPES OF TOXIC EFFECT" in red text. It lists the following effects:

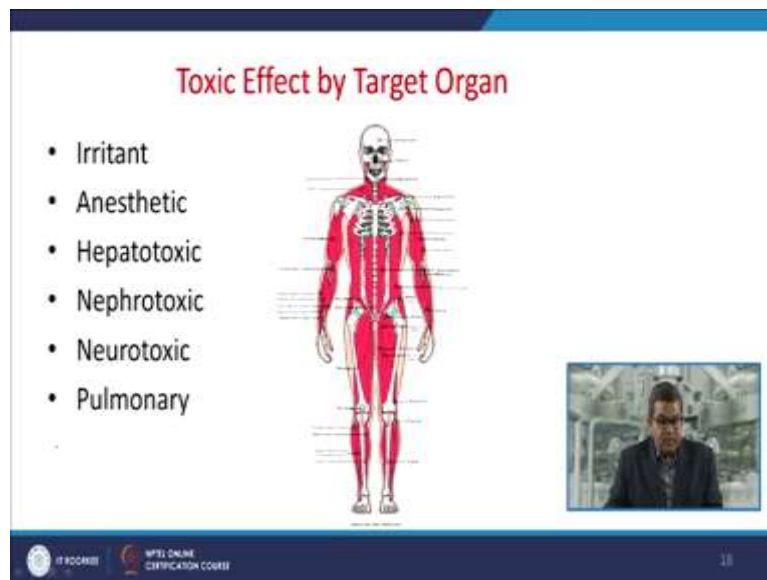

- Mortality
- Pathological change
- Growth rate change
- Physiological injury
- Biochemical change
- Behavioral effects
- Reproductive system damage
- Mutagenic, etc.

In the center of the slide is a black and white caduceus symbol. To the right of the list is a small video inset showing a man in a dark jacket speaking. At the bottom of the slide, there are logos for "IPTEL ONLINE CERTIFICATION COURSE" and the number "17".

Now, there are various type of toxic effects like mortality, pathological changes, sometimes the growth rate changes, physiological injury, the biochemical change, behavioural effect, sometimes reproductive system may get damage and there are mutagenic changes. So you must know that what kind of effect is going to take place within your body system by the exposure of any toxic substance.

Now, sometimes these toxicity or toxic effects are govern by the target organ. So you must know because sometimes if you inhale something first it goes to your upper or lower respiratory tract and then it may go into your lungs and if you sometimes if you take or if you things or any toxic substance through a dermal absorption then the target organ maybe little bit different. So you must know that which of the organ is going to be affected by any toxic substance which you are going to take.

(Refer Slide Time: 13:34)

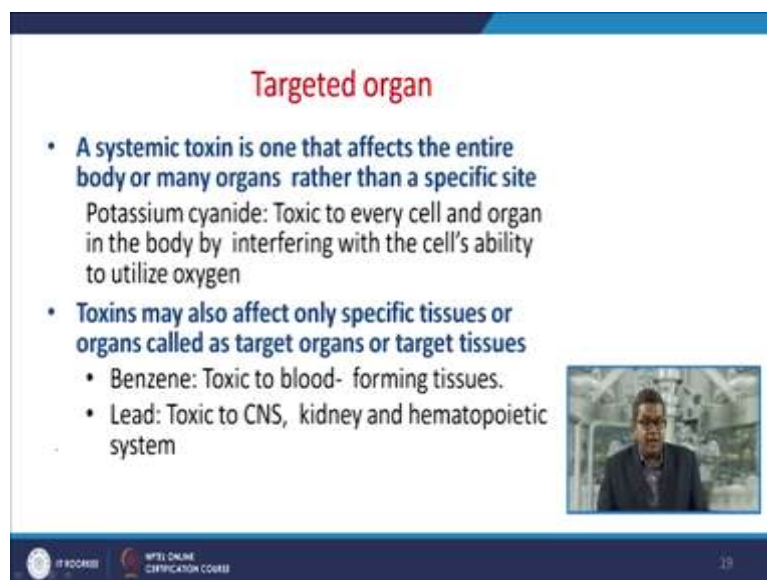

Toxic Effect by Target Organ

- Irritant
- Anesthetic
- Hepatotoxic
- Nephrotoxic
- Neurotoxic
- Pulmonary

The slide features a central anatomical diagram of a human figure with red lines indicating various target organs. A small inset video of a presenter is visible in the bottom right corner. The footer includes the IIT Kharagpur logo and the text 'NPTEL ONLINE CERTIFICATION COURSE'.

Now, these are the things which are important in this particular thing irritant sometimes suppose if you are exposed to the chlorine environment then first prima facie you may experience the irritation, then anesthetic, the hepatotoxic, nephrotoxic, neurotoxic and sometimes pulmonary so you must identify the target organ.

(Refer Slide Time: 13:44)

Targeted organ

- **A systemic toxin is one that affects the entire body or many organs rather than a specific site**
Potassium cyanide: Toxic to every cell and organ in the body by interfering with the cell's ability to utilize oxygen
- **Toxins may also affect only specific tissues or organs called as target organs or target tissues**
 - Benzene: Toxic to blood-forming tissues.
 - Lead: Toxic to CNS, kidney and hematopoietic system

The slide features a small inset video of a presenter in the bottom right corner. The footer includes the IIT Kharagpur logo and the text 'NPTEL ONLINE CERTIFICATION COURSE'.

Now, target organ that is a systematic toxin is one that affects the entire body or many organs rather than a specific site. Like potassium cyanide, toxic to every cell and organ in the body by interfering with the cells ability to utilize oxygen. The same happened in the Bhopal Gas Tragedy. The toxin may affect also affect only to specific tissues or organs they are called the target organ or the target tissues like; Benzene toxic to blood forming tissues, Lead toxic to

CNS, kidney, hematopoietic systems. So you must know that which kind of toxin and which kind of toxic substance is there.

(Refer Slide Time: 14:34)

Target Sites

- Adverse effects occur at the level of the molecule, cell.
- Molecularly, chemical can interact with
 - Proteins
 - Lipids
 - DNA
- Cellularly, chemical can
 - interfere with receptor-ligand binding
 - interfere with membrane function
 - interfere with cellular energy production
 - bind to biomolecules

The slide includes a small video inset of a presenter in the bottom right corner and a footer with logos for IIT Bombay and NPTEL Online Certification Course, along with the slide number 20.

The adverse effects occur at the level of molecular cell. The molecularly, chemical can interact with the proteins, lipid, DNA. Cellularly, chemicals they can be effected by interfere with the receptor ligand bindings, interfere with the membrane function, interfere with the cellular energy production, bind to the biomolecules. Remember all four factors they play a very vital role when you study the toxicological effect for the later part of life.

(Refer Slide Time: 15:06)

Factors Influencing Intensity of Toxic Action

- Route of entry
- Rate of exposure
- Age of host
- Prior exposure
- Environment
- Host factors
 - gender, genetics
- Other factors

The slide features a central diagram with two blue arrows pointing towards each other, with red lightning bolts between them, symbolizing the interaction of factors. It also includes a video inset of the presenter and a footer with logos for IIT Bombay and NPTEL Online Certification Course, along with the slide number 21.

Now, there are various factors influencing the intensity of toxic action. Usually they depend on route of entry if it is being inhaled by your nose then definitely at what part is going to effect, then the rate of exposure sometimes acute, sometimes chronic, sometimes the concentration of toxic is on the higher side then you may get exposed more spontaneously, then age of your body system. Suppose if I am young my physic is good then there is a prominent production of different fatty tissues within my body system then I may be in a position to retaliate all those toxic exposure so it all depend on age of host and suppose a person is old then definitely because of lesser number of excretion routes he or she may be get exposed on a dangerous level.

Then prior exposure sometimes you are acclimatized to the system of toxic environment then definitely all those exposure may play a vital role for the multiple exposures, then environment suppose I am working in a humid environment and most of the toxicants they are hygroscopic in nature so they may get deposited in your body system or they may enter into your body system through the skin or inhalation or sometimes ingestion.

Again the host factor that is your human body that is gender male or female, genetics what is your pedigree, et cetera and there are several other factors which we are going to discuss in due course of time.

(Refer Slide Time: 16:54)

How Toxicants Enter Organism

- Inhalation (mouth or nose to lungs) then into blood(+*)
- Ingestion (mouth to stomach) then into blood(+)
- Injection (cuts, punctures in skin) into blood
- Dermal absorption (through skin) into blood(+*)
 - + Involve membrane transport
 - * Greatest threats in industry

Of the four routes of entry, the inhalation and dermal routes are the most significant to industrial facilities.

22

Now, first question arises that how toxicant can enter into biological system? First is inhalation through mouth, nose to lung and then into the blood stream. Ingestion via mouth to stomach, suppose by mistake you have taken the benzene, benzene is available in both liquid

create a problem. Injection, inhalation and dermal absorption generally result in the toxicant entry into the blood stream they are usually unaltered.

(Refer Slide Time: 21:12)

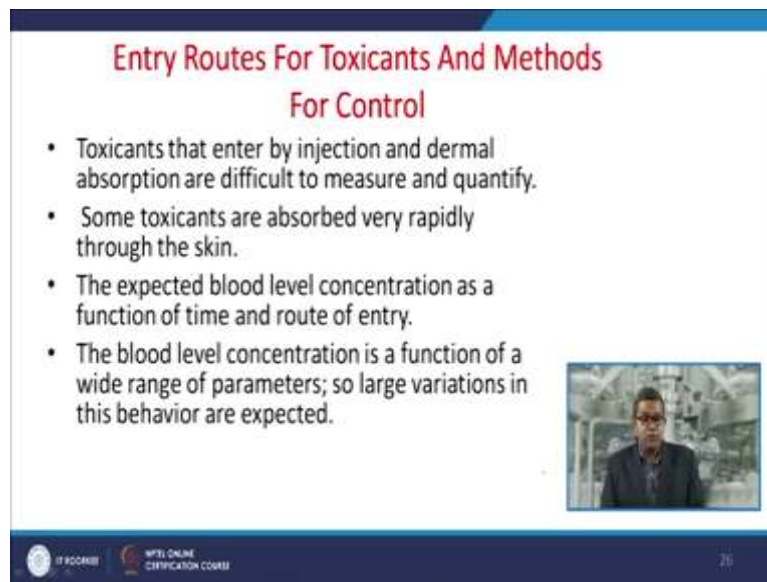

Entry Route	Entry Organ	Method for Control
Ingestion	Mouth or Stomach	Enforcement of rules on eating, drinking and smoking
Inhalation	Mouth or nose	Ventilation, respirators, hoods and other personal protection equipments
Injection	Cuts in skin	Proper protective clothing
Dermal absorption	Skin	Proper protective clothing

Now, in this particular table we can summarize that there are four different entry route, ingestion the entry organ is mouth or stomach you can control this entry by the enforcement of rules on eating, drinking and smoking. Inhalation that is again from the mouth or nose, you may adopt the method of control in terms of ventilation, respirator, hoods and other personal protection equipment so that the concentration of those toxicant may below the lower level.

Injection usually happens in the cuts in skin or through deliberation, you must have a proper protective clothing. Dermal absorption again it may happen or entry through the skin, you must have a proper protective clothing. So these four things are the rule of thumb and whenever you study the toxicological study you must know these four rule of thumb.

(Refer Slide Time: 22:22)

Entry Routes For Toxicants And Methods For Control

- Toxicants that enter by injection and dermal absorption are difficult to measure and quantify.
- Some toxicants are absorbed very rapidly through the skin.
- The expected blood level concentration as a function of time and route of entry.
- The blood level concentration is a function of a wide range of parameters; so large variations in this behavior are expected.

NPTEL ONLINE CERTIFICATION COURSE

26

Now, entry routes for toxicant and method for control deals with the toxicant that enter by the injection and dermal absorption are different to measure and quantify. Some toxicants are absorbed very rapidly through skin based on their molecular structure, based on their concentration to the atmosphere. The expected blood level concentration as a function of time and route of entry the blood level concentration is a function of a wide range of parameter, so large variation in this behaviour are expected.

Again there are because there are n number of parameters those who govern this particular aspect. So as an engineer we must identify that what are those parameters and if you are unable to find out those all those parameters you must enlist four, five different major parameters.

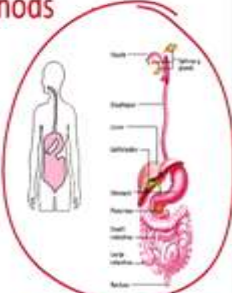

(Refer Slide Time: 23:14)

Entry Routes For Toxicants And Methods For Control

- The gastrointestinal (GI) tract, the skin, and the respiratory system play significant roles in the various routes of entry.

The Gastrointestinal (GI) Tract

The GI tract plays the most significant role in toxicants entering the body through ingestion. Food or drink is the usual mechanism of exposure. Airborne particles (either solid or liquid) can also lodge in the mucous of the upper respiratory tract and be swallowed.

27

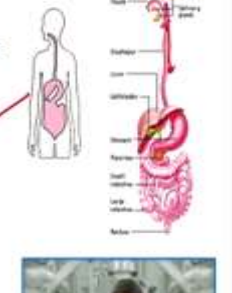

The first prominent route of toxicant entry into the biological system is gastrointestinal tract, the gastrointestinal tract apart from skin and other respiratory system plays a significant role in the various route of entry. The GI tract as depicted in this particular figure plays a most significant role in toxicant entry entering the body through ingestion. Food, drink is the usual mechanism of exposure. Airborne particles either solid or in a liquid form can also lodge into the mucous and the upper respiratory tract and be swallowed.

(Refer Slide Time: 23:55)

Entry Routes For Toxicants And Methods For Control

The rate and selectivity of absorption by the GI tract are highly dependent on many conditions like;

- The type of chemical and its molecular weight ✓
- molecule size and shape ✓✓
- acidity ✓
- susceptibility to attack by intestinal flora ✓
- rate of movement through the GI tract, etc.

28

The rate and selectivity of absorption to the GI tract are highly dependent on many conditions that what kind of chemical and its molecular weight because the heavier the molecular weight the entry maybe a little bit different compared to the lighter molecular weight component, what is the molecular size and shape? Like benzene is having the cyclic molecule then it may

create other problems rather than the linear molecules, what is the acidity and basicity of the component? What are the chances to attack by the intestinal flora because I told you that your body system is designed in such a way that it retaliates to the foreign body and suppose you encounter with the toxic substance so initially your intestinal flora attack to that particular toxic substance.

The rate of movement of that particular component to the GI tract that is again based on this parameter and molecular size and shape.

(Refer Slide Time: 25:04)

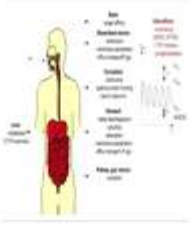

Distribution

Blood carries the agent to and from its site of action, storage depots, organs of transformation, and organs of elimination

Rate of distribution (rapid) dependent upon blood flow

characteristics of toxicant (affinity for the tissue, and the partition coefficient)

Distribution may change over time

#FOODSIS | NPTEL ONLINE CERTIFICATION COURSE | 29

Now, next aspects when this toxic substance enters through your GI tract the next concept is how it distributed to your body system? So blood carries this is usually they are carried by the blood stream, so blood carries the agent to and from its site of action, storage depots storage depots sometimes the fatty tissues, bone marrows, et cetera organs of transformation and organs of elimination.

Now, rate of distribution depends upon the blood flow characteristics of toxicant affinity for the tissues and partition coefficients and distribution may change over the time. Again there are several factor govern this particular aspect that is what is the molecular size, molecular weight, age of the host, etc.

(Refer Slide Time: 25:58)

The Skin

- Skin plays important roles in both the dermal absorption and injection routes of entry.
- Injection includes both entry by absorption through cuts and mechanical injection with hypodermic needles

#FOODSIS | NPTEL ONLINE CERTIFICATION COURSE | 30

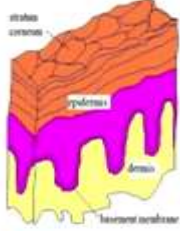

The next route of entry is your skin. Skin plays important role in both the dermal absorption and injection route of entry. Now injection includes both entry of absorption through cut and the mechanical injection with the hypodermic needles. So usually sometimes either in the medicinal way or sometimes deliberately this type of effect plays a vital role.

(Refer Slide Time: 26:24)

The Skin

Schematic representation of human skin

- Stratum corneum is the top of the five layers making epidermis, it is composed of keratinised dead cells glued by lipids.
- It is shed off and replaced every two weeks. Depending on the part of the body its thickness varies from 0.05 mm to 1.5 mm.

IFPCCBSI WPEL ONLINE CERTIFICATION COURSE 11

Now, this is the schematic representation of human skin. Now stratum corneum is at the top of the five layer making the epidermis usually composed of keratinised dead cells glued by the lipids. Now these are the keratinised cells glued by the lipids that lipids are fatty tissues. So whenever you are growing up or you are young those fatty tissues may get deposited over the period of time. And if after the aging these fatty tissues may get decomposed so it is quite evident that when you become older and older the wrinkles they form because of the decomposition of those fatty tissues.

So it is shed off and this stratum corneum it is shed off and replaced every two weeks, so depending on the part of the body its thickness varies from 0.05 mm to 1.5 mm, so most thickest part is your palm.

(Refer Slide Time: 27:30)

Respiratory System

The respiratory system plays a significant role in toxicants entering the body through inhalation.

The main function of the respiratory system is to exchange oxygen and carbon dioxide between the blood and the inhaled air.

Human Respiratory System Diagram

ANATOMY OF THE RESPIRATORY SYSTEM

Labels in the diagram include: Trachea, Bronchi, Lungs, Diaphragm, Pleural Cavity, and Pleural Membrane.

Labels in the anatomical diagram include: Nasal Cavity, Oral Cavity, Pharynx, Larynx, Trachea, Bronchi, and Alveoli.

Labels in the alveolar diagram include: Alveolar Sac, Alveolus, and Capillary.

IT 4000333 NPTEL ONLINE CERTIFICATION COURSE 32

The respiratory system, the respiratory system plays a significant role in toxicant entry into the body through inhalation, you can avoid, you can cover up your all skin but you cannot avoid the inhalation because you cannot avoid breathing. The main function of respiratory system is to exchange oxygen and carbon dioxide between the blood and inhaled air. So these are the main sects or alveoli or bronchi through which the carbon dioxide and oxygen they are exchanged from the blood stream.

So by any means if they get blocked then the available surface area for this carbon dioxide and oxygen exchange is diminished and you may experience a breathing problem. And sometimes there are so many chemicals those who destroy the active sides available at this port and sometimes certain solid particles those who are having the low size or in the micron size they may get deposited in these (())(28:28) by blocking the active surface area.

when we are discussing because we cannot overlook the importance of inhalation so you must know that which chemical affects which respiratory tracts! (Refer Slide Time: 29:46)

Respiratory System

- The upper respiratory tract is effected mostly by toxicants which are water soluble
- These materials either react or dissolve in the mucous to form acids and bases.

Components of the Upper Respiratory Tract

#FOONBI WPI ONLINE CERTIFICATION COURSE 35

The upper respiratory tract is effected mostly by the toxicants which are water soluble, remember your body is having sufficient quantity of water. These materials either react or dissolve in the mucous to form acid and bases.

(Refer Slide Time: 30:04)

Respiratory System

- Toxicants in the lower respiratory tract affect the alveoli by physically blocking the transfer of gases (as with insoluble dusts) or reacting with the wall of the alveoli to produce corrosive or toxic substances.
- Phosgene gas, for example, reacts with the water on the alveoli wall to produce HCl and carbon monoxide.

Components of the Lower Respiratory Tract

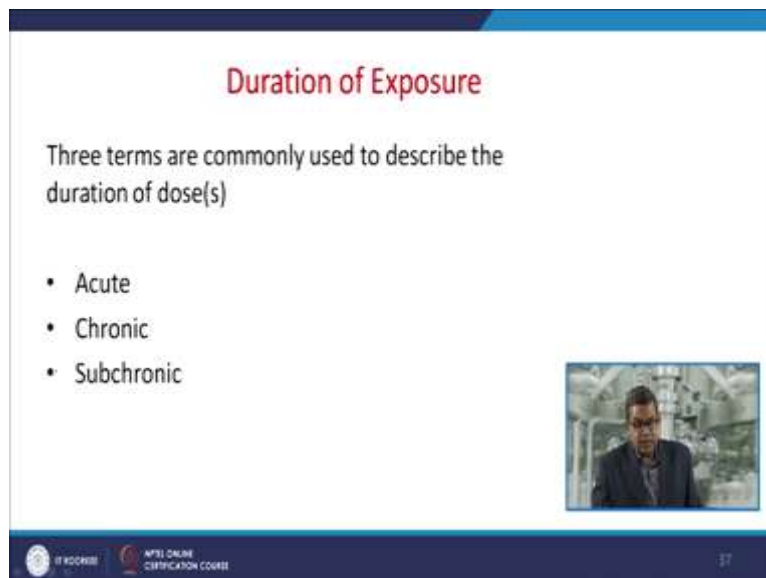

#FOONBI WPI ONLINE CERTIFICATION COURSE 36

The toxicant in the lower respiratory tract affect the alveoli by physically blocking the transfer of gases as with the insoluble dust or reacting with the wall of the alveoli to produce the corrosive or toxic substances. Remember phosgene, for example they reacts with the water on the alveolis wall to produce HCL and carbon monoxide and both the things are dangerous.

Like suppose, in case if you are in presence of phosgene gas and by any means you inhale this phosgene gas, so it may react with the water present in your body system or in your lungs or in your lower respiratory tract to produce the HCL and carbon monoxide, carbon monoxide is very reactive to your blood stream and HCL is having the corrosive property. So it may destroy the inner wall of either alveoli or bronchi, so the blood vessel may get exposed, so they can be more reactive to a carbon monoxide.

And moreover, the available sites or the available surface area for oxygen carbon dioxide exchange diminishes, so be particular, so this is the effect of one of the effect of any toxic gas.

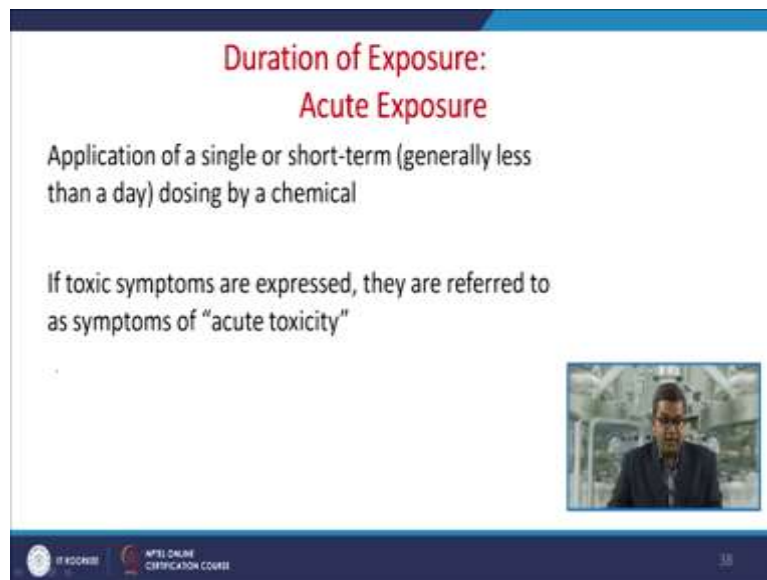

(Refer Slide Time: 31:20)

The slide is titled "Duration of Exposure" in red text. Below the title, it states "Three terms are commonly used to describe the duration of dose(s)". A bulleted list follows, containing "Acute", "Chronic", and "Subchronic". On the right side of the slide, there is a small video thumbnail showing a man in a suit. At the bottom of the slide, there are logos for "IIT KANPUR" and "NPTEL ONLINE CERTIFICATION COURSE", along with the number "17".

Now, as far as the toxic effects are concerned, it depends, another parameter is that duration of exposure, usually in engineering term we talk about three terms which are used to describe the duration of any dose or exposure Acute, Chronic, Subchronics. In the subsequent parts we will, we will study all these things under these three heads.

(Refer Slide Time: 31:45)

Duration of Exposure:
Acute Exposure

Application of a single or short-term (generally less than a day) dosing by a chemical

If toxic symptoms are expressed, they are referred to as symptoms of “acute toxicity”

© IIT Kharagpur | NPTEL ONLINE CERTIFICATION COURSE | 38

The slide features a blue header and footer. The main content is in black text on a white background. A small video inset in the bottom right shows a man in a dark suit and glasses speaking. The footer contains logos for IIT Kharagpur and NPTEL Online Certification Course, along with the slide number 38.

Now, Acute Exposure, application of a single or a short term generally less than a day dosing by a particular chemical or sometimes spontaneous exposure. Now, if toxic symptoms are expressed, they are referred as symptoms of “acute toxicity”.

(Refer Slide Time: 32:00)

Duration of Exposure:
Chronic Exposure

Expression of toxic symptoms only after repeated exposure to a chemical in doses regularly applied to the organism for a time greater than half of its life-expectancy

If toxic symptoms are expressed, they are referred to as symptoms of "chronic toxicity"

WPI ONLINE CERTIFICATION COURSE

29

Now, Chronic Exposure, the expression of toxic symptoms only after repeated exposure to a chemical in doses regularly applied to the organ for a time greater than half of its life expectancy. So, sometimes if you are working in say ammonia environment, so gradually you may get exposed to those environment and sometimes because of our nature of body we may get acclimatized and we cannot experience the adverse effect of ammonia and sometimes our body is acclimatized to give the prima facie symptom like suppose first hand if you expose to the chlorine environment, you may experience the irritation, you may experience the skin dryness, et cetera.

But if you are continuously working in that particular environment, your body may get tuned in such an environment so you may not experience, only thing you experience is if there is any change in the chlorine concentration, then you may experience that something going wrong. So this may be a chance of a chronic exposure.

Now, if toxic symptoms are expressed, they are referred to as the symptoms of "chronic toxicity".

(Refer Slide Time: 33:14)

Exposure: Duration

Over time, the amount of chemical in the body can build up, it can redistribute, or it can overwhelm repair and removal mechanisms

Effect	Time	Exposure pattern
Acute	<24 hours	Usually 1 exposure
Subacute	1 months	Repeated doses
Subchronic	1-3 months	Repeated doses
Chronic	>3 months	Repeated doses

The slide includes a table with handwritten red annotations. The 'Chronic' row is circled in red. Red arrows point from the 'Time' column to the 'Exposure pattern' column for each row. There are also red scribbles on the right side of the table.

Now, usually in this particular table discuss that over time, the amount of chemical in the body can build up, it can redistribute, or it can overwhelm repair and removal mechanisms. Because based on the duration, they may become the part and parcel of your blood stream and they may get deposited in the various your body parts of your human body.

Now, there are 4, 5 different fore effects. Acute, usually the time domain is less than 24 hours and sometimes it is attributed to 1 exposure.

The Subacute, the new term usually the time of exposure is 1 month and sometimes you may get the repeated doses. Repeated doses; sometimes every dose is not having the same concentration, sometimes it is on the higher side, sometimes it is on the lower side.

Subchronic, usually 1 to 3 months, repeated doses.

And the chronic one, it is greater than 3 months. So, suppose you are working in an industry and the work place is and your small dose, small amount of toxic release it may club under the head of chronic and you may experience the repeated doses, maybe the stagnant doses, maybe the fluctuating doses, so this is the exposure pattern.

So in this particular module, we have discussed about the different aspects of toxicity, the different definitions of toxic substance, toxic, toxicity, toxin, etc. Then different routes of entry through which any toxicant can become the part and parcel of your body system and what are the different qualitative analysis through which we can analyse the exposure of toxic substance. Thank you.
