Lecture – 47
Mass and energy balance equations in spherical co-ordinates

We were deriving balance equations for concentration energy in the previous lecture for a general situation where there are variations in the concentration or the temperature field in all 3 spatial directions as well as in time. The basic law was that the change in mass in a time delta t is equal to mass in minus mass out plus acceleration.

(Refer Slide Time: 00:58)

Balance equations:

$$\text{(Change in mass in time } t) = \text{(Mass in)} - \text{(Mass out)} + \text{Acc.}$$

$$[c(x, y, z, t + \Delta t) - c(x, y, z, t)] \Delta x \Delta y \Delta z$$

Mass in at surface $(y - \Delta y/2) = u_x c|_{x, y - \Delta y/2, z} \Delta x \Delta z \Delta t + \dots$

Mass out at surface $(y + \Delta y/2) = u_x c|_{x, y + \Delta y/2, z} \Delta x \Delta z \Delta t + \dots$

Mass in at $(x - \Delta x/2) = u_x c|_{x - \Delta x/2, y, z} \Delta y \Delta z \Delta t + \dots$

Mass out at $(x + \Delta x/2) = u_x c|_{x + \Delta x/2, y, z} \Delta y \Delta z \Delta t + \dots$

Mass in at $(z - \Delta z/2) = u_z c|_{x, y, z - \Delta z/2} \Delta x \Delta y \Delta t + \dots$

Mass out at $(z + \Delta z/2) = u_z c|_{x, y, z + \Delta z/2} \Delta x \Delta y \Delta t + \dots$

We had first done it for a Cartesian coordinate system where the x, y and z axis are perpendicular to each other, we had chosen a cuboidal volume whose surfaces are surfaces that are perpendicular to the coordinate axis. So, their surface is of constant coordinate and we had written a balanced equation for one such surface mass in minus mass out plus accumulation is equal to the change in mass in a time delta t. There are 6 phases, so there is mass in and mass out at 6 phases.

On 3 of these phases if the velocity is positive or the flux is positive, the mass is in and it increases the mass and on 3 others it is out and if they whole decreases the mass, mass in is going to be equal to the flux times the area times the time. Flux could be either due to convection or due to diffusion, the convective flux is the fluid velocity perpendicular to

the surface times the concentration and the diffusion diffusive flux is given by Fick's law for diffusion or Fourier's law for heat conduction.

(Refer Slide Time: 02:09)

$$\frac{\partial c}{\partial t} = -\frac{\partial}{\partial y}(u_y c + j_y) - \frac{\partial}{\partial x}(u_x c + j_x) - \frac{\partial}{\partial z}(u_z c + j_z) + S$$

$$\frac{\partial c}{\partial t} + \frac{\partial}{\partial x}(u_x c) + \frac{\partial}{\partial y}(u_y c) + \frac{\partial}{\partial z}(u_z c) = -\frac{\partial j_x}{\partial x} - \frac{\partial j_y}{\partial y} - \frac{\partial j_z}{\partial z} + S$$

$$j_x = -D \frac{\partial c}{\partial x}; \quad j_y = -D \frac{\partial c}{\partial y}; \quad j_z = -D \frac{\partial c}{\partial z}$$

$$\frac{\partial c}{\partial t} + \frac{\partial}{\partial x}(u_x c) + \frac{\partial}{\partial y}(u_y c) + \frac{\partial}{\partial z}(u_z c) = D \left[\frac{\partial^2 c}{\partial x^2} + \frac{\partial^2 c}{\partial y^2} + \frac{\partial^2 c}{\partial z^2} \right] + S$$

$$\frac{\partial T}{\partial t} + \frac{\partial}{\partial x}(u_x T) + \frac{\partial}{\partial y}(u_y T) + \frac{\partial}{\partial z}(u_z T) = \alpha \left[\frac{\partial^2 T}{\partial x^2} + \frac{\partial^2 T}{\partial y^2} + \frac{\partial^2 T}{\partial z^2} \right] + \frac{S}{\rho C_p}$$

$$u = u_x e_x + u_y e_y + u_z e_z; \quad j = j_x e_x + j_y e_y + j_z e_z$$

$$j = -D \left[\frac{\partial c}{\partial x} e_x + \frac{\partial c}{\partial y} e_y + \frac{\partial c}{\partial z} e_z \right] = -D \nabla c$$

And on that basis, I had derived an equation of this kind for you, the conservation equation and written it more compactly as follows is. So, this is the conservation equation slightly rewritten.

(Refer Slide Time: 02:15)

$$\frac{\partial T}{\partial t} + \frac{\partial}{\partial x}(u_x T) + \frac{\partial}{\partial y}(u_y T) + \frac{\partial}{\partial z}(u_z T) = \alpha \left[\frac{\partial^2 T}{\partial x^2} + \frac{\partial^2 T}{\partial y^2} + \frac{\partial^2 T}{\partial z^2} \right] + \frac{S}{\rho C_p}$$

$$j = j_x e_x + j_y e_y + j_z e_z$$

$$j = -D \left[\frac{\partial c}{\partial x} e_x + \frac{\partial c}{\partial y} e_y + \frac{\partial c}{\partial z} e_z \right] = -D \nabla c$$

So that the rate of change of concentration and the convective transport appears on the left side and the diffusive transport appears on the right side and then I write the flux in

terms of the grid the derivatives of the concentration field and get an equation for the for the concentration field that looks something like this.

(Refer Slide Time: 02:51)

$$u = e_x u_x + e_y u_y + e_z u_z \quad j = -D \left[e_x \frac{\partial C}{\partial x} + e_y \frac{\partial C}{\partial y} + e_z \frac{\partial C}{\partial z} \right]$$

$$j = e_x j_x + e_y j_y + e_z j_z \quad = -D \nabla C$$

$$\nabla = e_x \frac{\partial}{\partial x} + e_y \frac{\partial}{\partial y} + e_z \frac{\partial}{\partial z}$$

$$\frac{\partial C}{\partial t} + \frac{\partial}{\partial x} (u_x C) + \frac{\partial}{\partial y} (u_y C) + \frac{\partial}{\partial z} (u_z C) = -\frac{\partial j_x}{\partial x} - \frac{\partial j_y}{\partial y} - \frac{\partial j_z}{\partial z}$$

$$\frac{\partial C}{\partial t} + \frac{\partial}{\partial x} (u_x C) + \frac{\partial}{\partial y} (u_y C) + \frac{\partial}{\partial z} (u_z C) = -\nabla \cdot (j C)$$

$$\left(e_x \frac{\partial}{\partial x} + e_y \frac{\partial}{\partial y} + e_z \frac{\partial}{\partial z} \right) \cdot (C u_x e_x + C u_y e_y + C u_z e_z) = -\nabla \cdot (j C)$$

$$\left(e_x \frac{\partial}{\partial x} + e_y \frac{\partial}{\partial y} + e_z \frac{\partial}{\partial z} \right) \cdot (j_x e_x + j_y e_y + j_z e_z) = \nabla \cdot j$$

$$\frac{\partial C}{\partial t} + \nabla \cdot (j C) = -\nabla \cdot j = -\nabla \cdot (-D \nabla C) = D \nabla^2 C$$

$$\nabla^2 = \nabla \cdot \nabla = \left(e_x \frac{\partial}{\partial x} + e_y \frac{\partial}{\partial y} + e_z \frac{\partial}{\partial z} \right) \cdot \left(e_x \frac{\partial}{\partial x} + e_y \frac{\partial}{\partial y} + e_z \frac{\partial}{\partial z} \right) = \left(\frac{\partial^2}{\partial x^2} + \frac{\partial^2}{\partial y^2} + \frac{\partial^2}{\partial z^2} \right)$$

I would also derive for you rewritten this a little bit by defining vectors velocity vector of course, we know the velocity is a vector it has a direction and a magnitude at any point. The flux can also be written as a vector the flux as 3 components in the x, y and z directions which depend upon the derivatives in the x, y and z directions therefore, I can write the vector flux as the unit vector in the 3 directions times the component that gives a flux vector the resultant flux vector at a given location and I had also derived for you a vector derivative and in terms of this the conservation equation was quite easy.

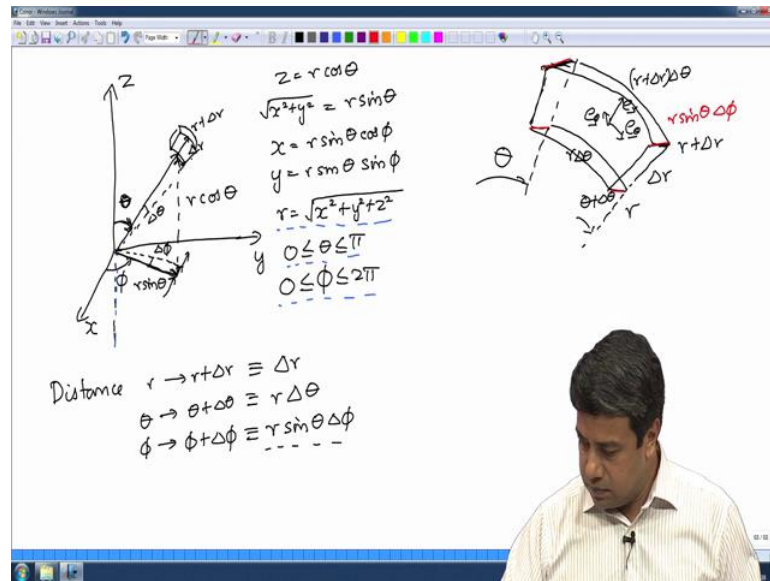

(Refer Slide Time: 03:36)

$$\left(\frac{\partial c}{\partial t} + \nabla \cdot (uc) \right) = D \nabla^2 c = -\nabla \cdot \mathbf{j}$$
$$\frac{\partial c}{\partial t} + \frac{\partial}{\partial x}(u_x c) + \frac{\partial}{\partial y}(u_y c) + \frac{\partial}{\partial z}(u_z c) = D \left(\frac{\partial^2 c}{\partial x^2} + \frac{\partial^2 c}{\partial y^2} + \frac{\partial^2 c}{\partial z^2} \right)$$
$$\nabla \cdot (uc) = \frac{\partial (u_x c)}{\partial x} + \frac{\partial (u_y c)}{\partial y} + \frac{\partial (u_z c)}{\partial z}$$
$$\nabla^2 = \frac{\partial^2}{\partial x^2} + \frac{\partial^2}{\partial y^2} + \frac{\partial^2}{\partial z^2}$$
$$\mathbf{j} = -D \nabla c$$

The conservation equation just contains the time derivative the divergence of the velocity times concentration, there is the convective part and the diffusive part which contains the laplacian of the concentration field.

The diffusive part is basically minus the divergence of the vector flux and that vector flux can be written terms of the diffusion coefficient using Fick's law for diffusion and based upon that we have got an equation which contains the divergence of the velocity times concentration on the left side and the laplacian of the concentration del dot del on the right side. So, those are the conservation equation. This is for a Cartesian coordinate system where the laplacian is at the second derivative in the 3 directions added up in general that is not the case and to illustrate that I had taken for you the example of a spherical coordinate system.

(Refer Slide Time: 04:42)

I just defined the coordinate for you in the previous lecture. Spherical coordinate system is useful whenever you are dealing with a configuration where the bounding surfaces have a spherical symmetry. I will show you a little later that the interpretation is a little more general there are many things that you can do in a spherical coordinate system which are not that easy to do in a Cartesian coordinate system.

But in general, it is useful whenever you have surfaces of spherical symmetry in that case you would prefer the surface to be a surface of constant coordinate; that means, that the distance from the center from the origin has to be one coordinate the center of the spherical geometry. So, that distance is the radial coordinate r . However, you need 2 other coordinates in order to completely specify a position in 3 dimensional space and those 2 other coordinates are expressed as angles.

The first one is the azimuthal angle theta which is the angle from the plus z axis theta is equal to 0 is the plus z axis and theta is equal to pi is the minus z axis theta is equal to phi is for minus z axis and; obviously, once you go all the way to the minus z axis you can go no further therefore, theta goes from 0 to pi. The projection of the radius vector onto the x y plane the angle that that makes with the x axis is phi it is called the meridional angle this goes around the z axis it goes around the z axis therefore, when you start along the x axis phi is equal to 0, you go all the way around the z axis and come back, you will find that phi is equal to 2 pi. Those are the axis.

As said this is also used for locating positions on spheres the earth for example, is sphere and if you want to locate a position on this sphere you need 2 angles in this particular case the z axis is the north south axis, the angle from the z axis can go from 0 to pi that is 0 to 180 conventionally that actually corresponds to the latitudes, but conventionally the latitudes go from 90 degrees on the north pole to minus 90 on the south pole. So, that is by convention.

If you want to define the angle from the north pole itself when theta would go from 0 to pi and the angle around the north south angle around the z axis is the meridional angle and that gives you the longitudes, the longitudes go from 0 to 360 they start at 0 and then they go all the way around to 360 that is the angle phi, in this case, the 0 longitude is the x axis. So, that is the coordinate system.

Now we have to construct a differential volume in this coordinate system, the differential volume are bounded by surfaces of constant coordinate, but first you have to first define what is the distance moved when these angles changed by a little bit because in the Cartesian coordinate system delta x delta y and delta z was the distances traveled, if you change x to x plus delta x, the distance traveled is delta x it has units of length all 3 coordinates have units of length.

In a spherical coordinate system, all 3 coordinates do not have units of length 2 of these are angles therefore, I need to define the distances carefully, when I travel from r to r plus delta r in the radial direction that distance is delta r itself. So, in the radial direction, if I go a small distance delta r in the radial direction to r plus delta r that angle is delta r itself now, how about if I change the theta coordinate from theta to theta plus delta theta by change the theta coordinate from theta to theta plus delta theta, what is the distance traveled? That distance traveled is going to be the radius times the angle it is going to be the radius times the angle in radian. So, this has to be equal to r times delta theta is the distance traveled when you go theta to theta plus delta theta the distance traveled is r times delta theta and when I go phi goes from phi to phi plus delta phi and I go a small distance delta phi along the phi coordinate when I increment phi by a small distance delta phi this distance is; obviously, the radius times delta phi the radius in this case is r sin theta. So, those are the distances that are traveled and; obviously, the volume of this any differential volume that you construct the 3 distances of that volume will be these 3.

Let me expand that hopefully for you, this surface here I take a surface at r and the surface at $r + \Delta r$ at θ and $\theta + \Delta \theta$ and then in the ϕ direction that surface will go from ϕ to $\phi + \Delta \phi$. So, let me construct that surface let me enlarge that surface for you I have a surface at r and the surface at $r + \Delta r$. So, this as the location r this is $r + \Delta r$ this distance is Δr . So, my differential volume is bounded by surfaces of constant coordinate surfaces of constant coordinate in the r direction r at r and $r + \Delta r$ surfaces of constant coordinate in the θ direction this angle is θ here this angle is θ here. So, this angle is θ and this angle is $\theta + \Delta \theta$.

It is bounded by 2 surfaces of constant θ at θ and $\theta + \Delta \theta$, the distance traveled in this is going to be $r \Delta \theta$ and over here it will be $r + \Delta r \Delta \theta$. So, those are the phases that are perpendicular to the r direction and perpendicular to the θ direction note that if I write some kind of a coordinate system, here the r direction will be in the direction of increasing r e r the θ direction will be the direction of increasing θ e θ the ϕ direction is along the $x y$ plane. So, it is perpendicular to both of these if ϕ direction is perpendicular to both of these it goes along the $x y$ plane. So, in the ϕ direction if you increment by a small angles ϕ right you get something that goes like this and these phases on the sides r at ϕ and $\phi + \Delta \phi$ these phases which are perpendicular to these 2 r at ϕ and $\phi + \Delta \phi$ and this distance that you travel in the ϕ direction this distance are you travel in the ϕ direction is going to be equal to $r \sin \theta$ times $\Delta \phi$ that is this distance in the ϕ direction so that is going to be $r \sin \theta \Delta \phi$.

This is the differential volume that I will construct 2 of the coordinates are perpendicular to the 2 of the surfaces are perpendicular to the r direction, 2 of the surfaces are perpendicular to the θ direction and 2 of the surfaces are perpendicular to the ϕ direction, 2 surface is perpendicular to the r direction that is the in this case the bottom and the top surfaces, 2 of the surface that are perpendicular to the θ direction that is the left and the right phases and 2 of the surfaces that are perpendicular to the ϕ direction and that is the in this case it will be the front and the rear 2 other surfaces that are perpendicular to the ϕ direction. That is a differential volume that I will construct.

(Refer Slide Time: 15:48)

Surface areas:

Surface at $r = (r \Delta \theta)(r \sin \theta \Delta \phi)$

Surface at $(r + \Delta r) = ((r + \Delta r) \Delta \theta)((r + \Delta r) \sin \theta \Delta \phi)$

Surface at $\theta = (\Delta r)(r \sin \theta \Delta \phi)$

Surface at $\theta + \Delta \theta = (\Delta r)(r \sin(\theta + \Delta \theta) \Delta \phi)$

Surface at $\phi = (\Delta r)(r \Delta \theta)$

Surface at $\phi + \Delta \phi = (\Delta r)(r \Delta \theta)$

Volume $= (\Delta r)(r \Delta \theta)(r \sin \theta \Delta \phi)$

(Change in mass) = (Mass in) - (Mass out) + Accumulation

Flux $= \underline{u} \cdot \underline{c} + \underline{j}$

$\underline{u} = u_r \underline{e}_r + u_\theta \underline{e}_\theta + u_\phi \underline{e}_\phi$

Now for this differential volume, I have to write a balanced equation and in that balance equation, I need to be able to identify all the surfaces first. So, the surfaces, this is at r and this distance is Δr ok this is at θ and this is at $\theta + \Delta \theta$ I moved the small distance θ and the $\Delta \theta$ and then I have this third phase which is perpendicular to the ϕ direction. So, this will be at the angle ϕ and this will be at the angle $\phi + \Delta \phi$ and I have to write a flux balance for these mass balance.

But first I have to identify the surface area of these surfaces, what is the surface area? Surface at r that is this surface the surface at r is this surface that is the surface at the location r perpendicular to the radial coordinate the surface area of that surface has to be equal to the length in the θ direction times the length in the ϕ direction that is the surface area the length in the θ direction is going to be equal to $r \Delta \theta$ the length in the ϕ direction is $r \sin \theta \Delta \phi$.

It is going to be the surface at the radial location r perpendicular to the r direction; the next is the surface in perpendicular to the radial coordinate at $r + \Delta r$, what is the surface at $r + \Delta r$? r is equal to $r + \Delta r$ $\Delta \theta$ into so, those are the 2 surfaces that are perpendicular to the r coordinate the blue ones are perpendicular to be r coordinate and then there are 2 surface that are perpendicular theta coordinate, there are 2 surfaces that are perpendicular to the theta coordinate because theta is increasing along this direction therefore, there are 2 surfaces that are perpendicular to the theta coordinate.

So, the surface at θ it is going to be equal to this distance Δr this distance Δr times the distance in the ϕ direction $r \sin \theta \Delta \phi$; if surface perpendicular to the θ direction is the distance in the r direction times the distance in the ϕ direction and similarly the surface at $\theta + \Delta \theta$ is equal to Δr into $r \sin$ of $\theta + \Delta \theta$ $\Delta \phi$. So, as θ is changing the surface area is also changing.

Those are the surfaces in the r direction, the surface is in the θ direction, now there are 2 surfaces in the ϕ direction the surface is in the ϕ direction r the surface in front and similarly there is a surface at the back those are the surfaces in which you increment the meridional angle ϕ . Therefore, the surface at ϕ surface at ϕ is going to be equal to Δr into $r \Delta \theta$ that is going to be equal to the distance traveled in the r direction times the distance traveled in the θ direction, that is going to be the surface area of the surface at ϕ and similarly you have surface at $\phi + \Delta \phi$ is equal to Δr times $r \Delta \theta$.

Those are the different surface areas and the total volume of the surface is going to be equal to Δr into the distance moved in the r direction times the distance moved in the θ direction times the distance moved in the ϕ direction so that is going to be equal to the total volume of this differential volume. And for these I have to write the balanced equation that is change in mass is equal to mass in minus mass out plus any accumulation and as I said the mass in and the mass out are equal to the flux times the area times time the flux consists of 2 parts flux, it consists of 2 parts, u times c plus j , the convective flux plus the diffusive flux where the velocity vector u is $u_r e_r$ plus $u_\theta u_\theta$ plus $u_\phi e_\phi$ the velocity is decomposed in terms of the components along the r direction.

At the local location, I can insert the coordinate system the e_r is along the direction of varying r e_θ is along the direction of varying θ and e_ϕ is along the direction of varying ϕ perpendicular to the plane e_r is along the direction where r changes it is a along with the direction of r θ changes because it is angled from the z axis. So, this is e_θ and if you have to decompose these into different components and then write the fluxes times the surface area at each of these.

(Refer Slide Time: 23:36)

$$\begin{aligned}
 & [C(r, \theta, \phi, t + \Delta t) - C(r, \theta, \phi, t)] \Delta V (r \Delta \theta) (r \sin \theta \Delta \phi) \\
 &= (u_r C + j_r) \Big|_r (r \Delta \theta) (r \sin \theta \Delta \phi) \Delta t - (u_r C + j_r) \Big|_{r+\Delta r} (r+\Delta r) \Delta \theta (r+\Delta r) \sin \theta \Delta \phi \Delta t \\
 &+ (u_\theta C + j_\theta) \Big|_\theta (\Delta r) (r \sin \theta \Delta \phi) \Delta t - (u_\theta C + j_\theta) \Big|_{\theta+\Delta \theta} (\Delta r) (r \sin(\theta+\Delta \theta)) \Delta t \\
 &+ (u_\phi C + j_\phi) \Big|_\phi \Delta r (r \Delta \theta) \Delta t - (u_\phi C + j_\phi) \Big|_{\phi+\Delta \phi} \Delta r (r \Delta \theta) \Delta t \\
 &+ \int \Delta r (r \Delta \theta) (r \sin \theta \Delta \phi) \frac{\partial C}{\partial t} \Delta t \\
 & \frac{C(r, \theta, \phi, t + \Delta t) - C(r, \theta, \phi, t)}{\Delta t} = \\
 & \frac{1}{(\Delta r)(r \Delta \theta)(r \sin \theta \Delta \phi)} \left[\begin{aligned} & (u_r C + j_r) \Big|_r r^2 \sin \theta \Delta \theta \Delta \phi - (u_r C + j_r) \Big|_{r+\Delta r} (r+\Delta r)^2 \sin \theta \Delta \theta \Delta \phi \\ & + (u_\theta C + j_\theta) \Big|_\theta \Delta r r \sin \theta \Delta \phi - (u_\theta C + j_\theta) \Big|_{\theta+\Delta \theta} \Delta r r \sin(\theta+\Delta \theta) \Delta \phi \\ & + (u_\phi C + j_\phi) \Big|_\phi \Delta r r \Delta \theta - (u_\phi C + j_\phi) \Big|_{\phi+\Delta \phi} \Delta r r \Delta \theta \end{aligned} \right]
 \end{aligned}$$

Let us proceed, first of all change in mass within the time in interval delta t, it is going to be equal to the concentration at r theta phi t plus delta t minus r, the concentration times the volume delta r, r delta theta into r sin theta delta phi so that is the change in mass within an time interval delta t is equal to mass in minus mass out mass in at the process at r. So, have this coordinate system once again so I will have a mass in at the surface at r because if the velocity is positive in the r direction the mass increases within in this volume and I have a mass out at r plus delta r. So, let us destroy the differential volume once again this is r, r plus delta r this is theta this is theta plus delta theta and the phi coordinate is perpendicular to both of these.

Mass in at the surface r it is going to be equal to u r times c plus j r at r times the surface area surface area perpendicular to the r direction I said was r delta theta into r sin theta delta phi. So, r delta theta is the angle is the length in the theta direction and r sin theta delta phi and length in the phi direction minus the mass out at the location r plus delta r minus I am sorry, I should multiply it by delta t as well because this is a flux times an area times time and this is r plus delta r delta theta times sin theta delta phi delta t.

Those are mass in and mass out at r and r plus delta r; plus mass in at theta and theta plus delta theta u theta c plus j theta at theta times the surface area. Surface area perpendicular to the theta direction surface area perpendicular to the theta direction that is the left and the right phases here: note that the theta direction were these 2, the phases that were

perpendicular to the theta direction the surfaces that are perpendicular to the r direction were these 2 and the phi direction were the front and the rear phases, the front and the rear phases.

Perpendicular to the theta direction what are the surfaces that are perpendicular to the theta direction? The surface area is Δr times $r \sin \theta$ $\Delta \phi$ times Δt . So, that is the flux times the surface area and what is going out at the surface at $\theta + \Delta \theta$. So, what I just use the flux in here, the flux out at the location $\theta + \Delta \theta$ is going to be equal to $-u_\theta c + j_\theta$ at $\theta + \Delta \theta$ into Δr into $r \sin \theta$ into Δt and then I have the surfaces the front and the rear at ϕ and $\phi + \Delta \phi$.

I have to take the flux which is $u_\phi c + j_\phi$ at ϕ multiplied by the surface area the length in the r direction times the length in the theta direction $r \Delta \theta$ minus $u_\phi c + j_\phi$ at $\phi + \Delta \phi$ into Δr into $r \Delta \theta$. This the length, the surface area perpendicular to the phi direction is the length in the r direction times length in the theta direction perpendicular to the r direction is the length in the theta direction times the length in the phi direction and so on. And I have to multiply it by Δt here and now I have to divide throughout by volume and by time I have to divide by throughout by volume and by time, when I do that on the left side I will just get see at I should add the accumulation term here the accumulation term is just of the form total source times the volume $\Delta r r \Delta \theta r \sin \theta \Delta \phi$ times Δt .

Now, I have to divide throughout by volume and by time, on the left side the term will just be equal to c at $r \theta \phi$ $t + \Delta t$ minus c at $r \theta \phi$ t by Δt . On the right side I will have 1 over Δr into $r \sin \theta \Delta \theta$, I am sorry; $r \Delta \theta$, $r \Delta \theta$ into $r \sin \theta \Delta \phi$ into $u_\theta c + j_\theta$ at θ we will expand this at r into $r + \Delta r$ the whole square plus $u_\theta c + j_\theta$ at $\theta + \Delta \theta$ times Δr into $r \sin \theta \Delta \phi$ minus $u_\theta c + j_\theta$ at θ plus $\Delta \theta$ into Δr into $r \sin \theta$ plus $\Delta \theta \Delta \phi$ plus $u_\phi c + j_\phi$ at ϕ into Δr into $r \Delta \theta$ into just dividing throughout by volume and by time.

You can see that for each of these terms certain intervals will cancel out for example, in the first term $\sin \theta \Delta \theta$ and $\Delta \phi$ will cancel out, but I will have a 1 over Δr in the denominator. Similarly for the second term Δr and $\Delta \phi$ $r \Delta \phi$

will cancel out, in the third term Δr and $r \Delta \theta$ will cancel out. So, this is the difference equation now we have to reduce it to a differential equation.

So, I will continue the reduction of this now to a differential equation we will continue that in the next lecture. Please go through this and familiarize yourself with the way the differential volume is constructed, what are the lengths of all the size of the differential volume, but on the surface areas once you have done that correctly then you know what is the mass in and the mass out by just multiplying the flux times the surface area. We will continue this in the next lecture, I will see you then.
