

Electrochemical Technology in Pollution Control
Dr. J. R. Mudakavi
Department of Chemical Engineering
Indian Institute of Science, Bangalore

Module IV
Lecture – 06
Properties of solution 3

We are meeting again to continue our discussion on the Electrochemical Technology. I have been trying to introduce you to solution chemistry as part of the course and we had discussed about activity and activity coefficient in the last class. We can look at the slide now.

(Refer Slide Time: 00:48)

Activity and Activity coefficient

A rigorous thermodynamic equilibrium constant for the reaction is given by

$$K_a = \frac{a_{A^+} \times a_{B^-}}{a_{AB}}$$

$a+b \rightarrow ab$
 $c_A \quad c_B \rightarrow c_{AB}$

Where a_{A^+} , a_{B^-} and a_{AB} represent the activities of A^+ , B^- and AB respectively. Activity may be defined as the effective concentration of a species

Activity = concentration $\times$ activity coefficient
= $[A^+] \cdot f_{A^+}$

Here I have written an equation it is a plus b going to a b; I am the concentrations are here and but instead of concentrations thermodynamically to be very correct; we should write a A plus

and a_B into a_B plus divided by a_{AB} . Here a_A represents the activity of A, a_B represents activity of B and a_{AB} represents the activity of AB product.

(Refer Slide Time: 01:34)

$$\text{Hence } K_a = \frac{[A^+][B^-]}{[AB]} \times \frac{f_{A^+} \times f_{B^-}}{f_{AB}}$$

$$\text{Ionic strength } I = 0.5 \sum_{i=1}^{i=n} c_i Z_i^2$$

Where c_i is the ionic concentration in gram - molar liter of solution and z_i is the valency of the ions.

The activity coefficient depends upon the total ionic strength of the solution. For weak electrolytes activity coefficient approaches unity. Hence K_a and K_a become equal.

So, Activity is defined as the concentration into activity coefficient. We had also discussed about the a little bit about the ionic strength, that is the activity is nothing but co activity coefficient into concentration. So, we are defined ionic strength as the total number of ions present and their product of ionic concentration and valency, some of that and approximately 50 percent as the ionic strength.

(Refer Slide Time: 02:07)

Acid - Base Equilibrium in water

For a weak electrolyte such as acetic acid we can write

If one gram equivalent of the acid is dissolved in V liters ($V=1/C$) and if α is the degree of dissociation at equilibrium then the amount of unionized electrolyte will be $(1-\alpha)$ gram equivalents and the amounts of ionized electrolytes will be α gram equivalents each. Hence

$$K = \frac{\alpha^2}{(1-\alpha)V} \quad \text{or} \quad \frac{\alpha^2 C}{(1-\alpha)}$$

So, then we discussed about the acid base equilibrium reaction, we have written say acetic acid plus H₂O going to H₃O⁺ plus and CH₃COO⁻ minus. We write an equilibrium reaction constant K is equal to CH₃COO⁻ minus and H⁺ plus into CH₃COO⁻ minus CH₃COOH. And if one gram equivalent is there and a small portion that is alpha dissociates into the products. I can write undissociated product would be 1 minus alpha.

(Refer Slide Time: 02:55)

The values of α can be determined experimentally by determining equivalent conductance (λC) of the analytical solution and conductance at infinite dilution.

The dissociation constants of weak acids are available in databases and for acetic acid it is 1.85×10^{-5}

For weak bases we can take ammonia as an example.

$$K_b = \frac{[\text{NH}_4^+][\text{OH}^-]}{[\text{NH}_3]}$$

$$K_b = K_w / K_a$$

So, I can write instead of H_3O^+ plus and CH_3COO^- minus I can write α α . So, $\alpha^2 C$ divided by $1 - \alpha$ into V that is $\alpha^2 C$ divided by $1 - \alpha$. So, this is the dissociation constant and the values of α can be determined experimentally by determining the equivalent conductance. Because, those things these H_3O^+ plus and CH_3COO^- minus contribute to the conductance this will not contribute.

So, I can determine the conductance and take 50 percent has H_3O^+ plus and 50 percent as CH_3COO^- minus of the total conductivity ok. So, that is λC of the analytical solutions and we assume that it is the conductance at infinite dilution. So, the dissociation constants of weak acids are available in the literature. And now up to this who had done earlier.

Now we are going to discuss about the weak basis that is dissociation of weak basis. Just like acids we also have basis, basis can be strong bases and weak basis; sodium hydroxide,

potassium hydroxide they are all strong basis, ammonia is a weak base. So, you can smell ammonia very easily you know, because it is a weak base.

So, ammonia will react with water to give you ammonium hydroxide, the reaction is represented like this NH_3 plus H_2O going to NH_4^+ plus and OH^- minus. There is another equilibrium that is present in aqua solutions, that is water itself can dissociate as H^+ plus and OH^- minus going to H_2O .

So, I can write K_b is nothing but $\frac{[\text{NH}_4^+][\text{OH}^-]}{[\text{NH}_3]}$ that is the product. We do not write the concentration of water, because it is very large compared to NH_3 . So, it is we assumed that it is 1 all others are very small. So, we have K_b where dissociation constant of ammonia is nothing but $\frac{[\text{NH}_4^+][\text{OH}^-]}{[\text{NH}_3]}$ plus.

And I can write an equilibrium constant there will because this is equilibrium equally available. Simultaneously going on I can write K_b is equal to K_w by K_a ; this is the equivalent concentrations of water is written as K_w . I can write here similar equation H^+ plus into OH^- minus divided by H_2O that is K_w .

(Refer Slide Time: 05:48)

Since values of K_b and K_a vary over several powers of 10

We use $pK = -\log_{10} K$

Larger the pK_a weaker is the acid and stronger is the base.

Larger the pK_b weaker is the base and stronger is the acid.

Common ion effect

The concentration of a particular ion can be increased by the addition of another compound which produces the same cation or anion.

e.g. $CH_3COOH \rightleftharpoons CH_3COO^- + H^+$

To this solution if we add sodium acetate we have another equilibrium in the same solution.

$CH_3COONa \rightleftharpoons CH_3COO^- + Na^+$

So, since values of K_b and K_a vary over several powers of 10, that is you remember what is the value of K_a that is for acetic acid? It is 1.85×10^{-5} who will remember so much, you know 10^{-5} times 10^{-6} for day to day life it does not make much sense to remember all these.

So, what we do is, we write use a value that is logarithms. So, 10^{-5} is 5 minus 5 and $\log$ of 10^{-5} . So, we use pK as we defined pK has negative $\log$ of K to the power of to the base of 10. So, here if I write 10^{-5} , it will be larger there it will be 5 point something; 4.87×10^{-5} that is what it means pK .

So, larger the pK weaker is the acid and stronger is the base; this is the ultimate conclusion of the pK value. So, if you see the value of pK in it means you are seeing the value of negative $\log$ of $10 K$. So, if pK is larger the acid is weak and base is strong. So, larger pK_b weaker is

the base and stronger is the acid very simple to understand. And this is about the dissociation constant.

Now, I will discuss about the common ion effect, that is concentration of a particular ion in a solution can be increased by the addition of another compound which produces the same cation anion. I want you to imagine that we are having a particular solution of acetic acid. Now acetic acid will dissolve into acetate ion and H plus ion, we have written the equation earlier, you can see the previous slides.

So, what we have written, CH_3COOH going to CH_3COO^- and H^+ ok. Now, to this solution containing CH_3COO^- and H^+ and CH_3COOH and dissociated acetic acid. To this if we add I want to add sodium acetate additionally from myself, then what happens we have another equilibrium means in the system is not it. So, look at the slide now, that is what I am going to explain to you.

Here I am writing CH_3COOH going to CH_3COO^- and H^+ ; to this solution we are going to add sodium acetate and we have another equilibrium for sodium acetate are separately. What is that equilibrium? Sodium acetate will decompose into CH_3COO^- and Na^+ .

So, if I add this there will be two equilibriums in their same solution; one is acetic acid another is sodium acetate. But, look at this; this CH_3COO^- is common here in this equation and CH_3COONa is also produce going to produce CH_3COO^- and Na^+ . In general you have to understand that 99 percent of the salts are ionized sodium salts are ionized 100 percent. All sodium salts and potassium salts 99 percent of them are totally ionized 100 percent ionize been solution.

So, if I add sodium acetate to acetic acid, what I am going to add 100 percent ionization. So, I am going to add CH_3COO^- ions to the same solution and a little bit 100 percent of sodium ions plus whatever they it can come from acetic acid in this case. So, in the solution, we have CH_3COO^- coming from this reaction another CH_3COO^- coming from this reaction Na^+ and H^+ . So, this is common so this is what we are discussing this is

what effect this addition of CH_3COO^- will have on the dissociation constant of CH_3COOH .

(Refer Slide Time: 11:27)

Unlike acetic acid sodium acetate is 100% ionized in solution. Therefore the concentration of $(\text{CH}_3\text{COO}^-)$ will be much more. This induces the backward reaction of acetic acid with the result that more acetate ions will be converted to acetic acid consequently (H^+) concentration also decreases.

So, unlike acetic acid sodium acetate is 100 percent ionized, therefore the concentration of CH_3COO^- will be much more than what is produced by the dissociation of acetic acid. So, this induces the backward reaction of the acetic acid, with a result that the acetate more acetate ions will be converted into acetic acid go back now.

Here I consider this now I have more of this and less of this more of this. So, remember Le Chatelier's principle, if I add additional CH_3COO^- into this system, the system should try to remove the addition. So, how will it remove the addition of CH_3COO^- it will combined more with H^+ and go back to CH_3COOH . That means, the dissociation of

acetic acid will become less to the extent of the effect of CH_3COO^- coming from sodium acetate.

So, this effect is known as common ion effect. So, Le Chatelier's principle is at work here and it will induce more of the acetate ions to get converted into acetic acid. So, this is the principle of common ion effect.

(Refer Slide Time: 13:26)

Solubility product

For sparingly soluble salts (<0.01 g.mol per litre) we can write

$$\text{AB(s)} \rightleftharpoons \text{A}^+ + \text{B}^-$$

e.g. $\text{AgCl(s)} \rightleftharpoons \text{Ag}^+ + \text{Cl}^-$

We can write an equilibrium constant involving both forward and reverse reactions just like dissociation constant.

$$S_{\text{AgCl}} = K_1/K_2 = \frac{[\text{Ag}^+][\text{Cl}^-]}{[\text{AgCl}]}$$

A large data base exists for the solubility products of various sparingly soluble salts.

Handwritten notes:

$$K_1 = \frac{[\text{Ag}^+][\text{Cl}^-]}{[\text{AgCl}]}$$

$$K_2 = \frac{[\text{AgCl}]}{[\text{Ag}^+][\text{Cl}^-]}$$

Forward

So, now we are going to talk about the solubility product. I have so far I have been trying to introduce you to different concepts of the aqueous chemistry. So, now we have discussed about activity, concentration, dissociation and then common ion effect and all those things.

Now, I am going to introduce to you one more one more property of the aqueous solutions. That means, they contain solutes dissolved in the solvents. So, we earlier we had talked about

solubility, now I am going to talk about the solubility product. Now look at the slide now, the I have a product salt AB, it is S I have written here, it is it represents sparingly soluble salt S means salt solid it can also represent solid.

So, for sparingly soluble salts what is sparingly soluble salt mean? It means you it is very soluble very less extent that means, even if you take the solid put it in water it will remain as such but water will be saturated with the ions of the salt. So, but very little salt will be dissolved in water, their such a thing is known as sparingly soluble salt.

For example, I can choose silver chloride; all students of chemistry or high school students, PUC student's, college students use it as a chemical test for the chloride. That is, if you add silver nitrate solution to a solution silver nitrate solution to a solution containing chloride, silver chloride will precipitate.

So, why silver chloride will precipitate? Because the solubility of silver chloride is very less in water, such a substance whenever there is a precipitation reaction happening it means the solubility is very less. Such product like silver chloride is known as sparingly soluble salt. It may be of the order of few milligrams per liter, milligrams few milligrams per liter or it may be few grams per liter. But definitely not more than that ok, it may be few micrograms per liter.

So, we are going to talk about such salts which are very sparingly soluble in water. So, for earlier you also remember that I have talked to you about the dissociation; all salts dissolved salts in water they dissociate into their corresponding anion and cations. Positively charged cations and negatively charged anions, sodium chloride will give you positively charged sodium negatively charged chloride ion.

So, I am going to write an equation for the equilibrium between undissociated salt and dissociated salt in water, in the aqueous solution. So, I write here AgCl this is a specific example AgCl solid is in equilibrium with Ag^+ plus and Cl^- minus ions. In water, this is the actual example this is the general example; AB solid is going to A^+ plus B^- minus.

So, we can write an equilibrium constant for this reaction, involving both forward and reverse reactions just like a dissociation constant. So, I write $S \text{ AgCl}$ that is at the bottom I should write Ag^+ plus Cl^- divided by AgCl you know. I can write an equilibrium constant K is equal to Ag^+ plus Cl^- divided by AgCl , this is also concentration.

Now, you should remember that AgCl is a solid ok, because it is very sparingly soluble. The product AgCl at the bottom is a solid, so concentration of solid is always one remember that you must always remember, that the concentrations of solids in their solid form is 1. So, I do not write I can simply write K is equal to Ag^+ plus, if the denominator is 1 I can write Ag^+ plus Cl^- is equal to K because of AgCl is 1.

So, here I am I am writing $S \text{ AgCl}$ is equal to Ag^+ plus Cl^- forward reaction. For the reverse reaction I should write, AgCl divided by Ag^+ plus Cl^- ; this is for the forward reaction. And K_2 I can write this I can write it as K_1 K_2 will be AgCl divided by Ag^+ plus Cl^- .

So, this is the ratio K_1 by K_2 here also it should be K_1 only no no. So, K_1 so K_1 by K_2 is nothing but the product of Ag^+ plus and Cl^- minus here it should be Ag ; there is an error typographical error g^+ plus is there. So, here it should be Ag^+ plus Cl^- because AgCl is 1. So, a large database exists again for the solubilities of sparingly soluble salts in water and several other solvents.

(Refer Slide Time: 21:13)

The ionic product of water

We can write $\text{H}_2\text{O} + \text{H}_2\text{O} \rightleftharpoons \text{H}_3\text{O}^+ + \text{OH}^-$

Applying the law of mass action to this equation at a given temperature we get

$$\frac{a_{\text{H}^+} \times a_{\text{OH}^-}}{a_{\text{H}_2\text{O}}} = \frac{[\text{H}^+][\text{OH}^-]}{[\text{H}_2\text{O}]} \times \frac{f_{\text{H}^+} \times f_{\text{OH}^-}}{f_{\text{H}_2\text{O}}}$$

or $[\text{H}^+][\text{OH}^-] = K_w = 1 \times 10^{-14}$ → $\text{H}^+ = 10^{-7}$
 $\text{OH}^- = 10^{-7}$

K_w is known as ionic product of water expressed in gram ions per litre. Since in pure water $[\text{H}^+]$ and $[\text{OH}^-]$ concentrations are equal, ($= 10^{-7}$ g ions/litre) it is called as neutral solution.

If $[\text{H}^+] > 10^{-7}$ it is called as acid and if $< 10^{-7}$ it is base.

So, I will now discuss more about sparingly soluble salts but, you are introduced to the concept now is not it. Now I want to introduce you to another property of the solutions that is ionic product of water. What can do what can happen water do? One molecule of water may react with one more molecule of water to give you H_3O^+ plus and OH^- minus here it should be H_3O^+ plus positive charged it is a cation ok, so H_3O^+ plus into OH^- minus ion.

So, we can apply the same law of mass action or equilibrium constant to this reaction and I can write a H^+ plus activity of the hydrogen ion into activity of OH^- minus ion divided by activity of H_2O water molecules and I can write convert it into concentration because it is only pure water. So, the reaction can be written in terms of concentrations and activity products.

And activity products are one almost in all water solutions. So, I can write this is one H_2O the value of H_2O would be 1 and these are all 1×1 into 1 divided by 1. So, I can write the product of H^+ and OH^- ion is equal to the a constant; that is it known as K_w very popularly know people write this K_w . Every time you write our dissociation of water is simply write K_w .

So, the this value you should always remember that it is 1×10^{-14} sorry 10^{-14} . So, what would be the value of H^+ ? H^+ would be 10^{-7} and OH^- also should be equal to 10^{-7} . Then only K_w would be 1×10^{-14} .

So, this K_w is known as ionic product of water because it is the multi product two values are two values are there which is 10^{-7} and 10^{-7} . So, H^+ is equal to 10^{-7} OH^- ion concentration is equal to 10^{-7} . So, it is called as neutral solution. So, H^+ is greater than 10^{-7} we call it as acidic and if H^+ K_w H^+ is less than 10^{-7} then it is called as basic solution base solution. So, this concept of ionic product of water is a very important concept.

(Refer Slide Time: 25:01)

The pH

To express the hydrogen ion concentrations S.P.L. Sørensen proposed that the logarithm to the base of 10 of the reciprocal of the hydrogen ion concentration be called pH.

$$\text{pH} = -\log_{10}[\text{H}^+] = \log_{10} 1/[\text{H}^+] \text{ or } 10^{-\text{pH}} = 10^{-\text{pOH}}$$

If $[\text{H}^+] = 10^{-7}$, $[\text{OH}^-] = 10^{-7}$, $K_w = 10^{-14}$ and $\text{p}K_w = 14$

So, that brings us to the discussion of what is a pH. So, you should remember that we are writing almost all things in the negative log domain. So, to express the hydrogen ion concentration again, in pure water it is H^+ is 10 raised to minus 7 and then in acidic solutions it may be 10 raised to minus 2 10 raised to minus 5 , it may be 10 raised to minus 1 it can be anything.

So, again this 10 raised to minus 7 exponential terms are difficult to handle difficult to remember. So, the concept of log value has been introduced and even to write the H^+ concentration. We this gentlemen he is a great scientist actually S.P.L. Sørensen proposed that instead of writing 10 raised to minus so much so much so much etcetera, he simply used write it has negative log of concentration that will be very simple number.

So, he is suggested that use logarithm to the base of 10. So, according this is very widely accepted all over the world. So, p H it is called as p H is negative log of H plus ion that is $\log$ of one plus 1 divided by H plus; this is nothing this expression can also be written like this or 10 raise to minus p H or 10 raise to minus p OH.

So, if H plus is 10 raise to minus 7, OH is 10 raise to minus 7, K w 10 raise to minus 14 p K w is 14. It becomes instead of 10 raise to minus 14, it becomes 10 raise to 14 this is this becomes 10 raise to minus 7. But in pH scale it becomes 7 this becomes this is concentration is 7. And if there is no OH plus, it becomes 10 raise to minus 7.

So, K w is 10 raise to minus 7. So, there are 7 regions of OH minus 7 numbers up to 7 and 7 numbers for hydrogen. So, we say p H 7 do we divide p Kw 14 exactly so half of this is 7. So, pH 7 is a neutral solution anything above that 8, 9, 10, 11 etcetera. Then it is a basic solution and if it is less than that it is acidic solutions.

(Refer Slide Time: 28:20)

The hydrolysis of salts

There are four main classes of salts.

- i. Salts of strong acids and strong bases. NaCl, KCl, KNO₃ etc
- ii. Salts of strong acids and weak bases. NH₄Cl
- iii. Salts of weak acids and strong bases. CH₃COONa
- iv. Salts of weak acid and weak bases. COONH₄, (CH₃COO)₃Al

Interaction with water may change it neutral or acidic or alkaline.

So, we have this expression, the next thing we want to discuss is about the hydrolysis of the salts. So, what kind how many salts are there? There are n number of salts thousands of salts. But many of the salts dissolve in water and that process is known as hydrolysis. So, I can have there are four kinds of salts, salts of strong acid hydrochloric acid you all know.

So, a salt of strong acid like sodium chloride, potassium chloride, potassium nitrate etcetera. And, that is sodium chloride they are all salts of strong acid and strong basis ok. And then salts of strong acids and weak basis are there ammonium chloride, ammonia is a weak base chloride is a salt of strong base. So, I have here salt of strong acid and weak base ammonia is a weak base.

So, sodium chloride weak base and strong acid strong base sodium sodium hydroxide is a strong base, hydrochloric acid is a strong base. So, NaCl is a strong base salt of strong acid

and strong base. So, KCL also ditto KNO₃ it is salt of nitric acid here I have salt of strong acid and weak base you remember like this. And then, salt I can have salt of weak acid and strong base CH₃COONa; this is a strong base if I make a base out of this add a OH it becomes a very strong base, CH₃COO minus is a weak base weak acid.

Then I can have salts of weak acid and strong base weak acid and weak base, ammonium acetate CH₃ COONH₄ or CH₃COO thrice aluminum acetate; these are all aluminum is also very weak base acetic acid is also a weak acid. So, I have salt of weak acid and weak base. So, interaction with water of all such salts of all the salts may change it to neutral or acidic or alkaline any of these things is not it. Because, they all they are all going to dissociate in water.

(Refer Slide Time: 31:33)

Case 1 : Strong acid - strong base [H⁺] and [OH⁻] equilibrium is not disturbed and the solution remains neutral.

Case 2 : Weak acid-strong base

$$pK_h = pK_w - pK_a$$

$$pH = 1/2 pK_w + 1/2 pK_a + 1/2 \log C$$

Case 3 : Strong acid - weak base

$$pH = 1/2 pK_w - 1/2 pK_b - 1/2 \log C$$

Case 4 : weak acid - weak base

$$pH = pK_a + \log (\text{Salt/Acid}) \text{ or}$$

$$pOH = pK_b + \log (\text{Salt/Acid})$$

So, I have a case 1 here strong acid and strong base, that is H plus and OH minus ion equilibrium is not disturbed and the solution remains neutral. If I take a strong acid and strong

base salt of a strong acid and strong base, I have only H plus and OH minus ions are not disturbed.

So, NaCl where is H plus and where is OH minus in NaCl? Nothing so, Na plus and Cl minus will be there so, the pH will remain constant it will not change if I put it in water. So, but if I take weak acid and strong base salt then what happens? pH would be the half of this pK_w that is dissociation constant of the water and dissociation constant of the acid plus $\frac{1}{2} \log$ of concentration of the salt. So, there is a certain amount of derivation of this equation in the book by Vogel third edition quantitative inorganic chemistry. And this expression is usually used to determine the pH of a solution containing a salt of a weak acid and strong base.

Here if I know the concentration of the salt, I can this is the this data pK_w and pK_a are available from database, pK_w is always 14 you know, so half of pK_w is 7. So, I can always calculate what is the pH. pH measurement is a day to day affair in all chemistry labs and pollution control labs.

So, it is in whatever you do you whatever salts you have the one of the activities to find out the pH of the solutions. So, if I have a salt of strong acid and weak base, I can write an equation expression like this $\frac{1}{2} pK_w - \frac{1}{2} pK_b - \frac{1}{2} \log C$ that will give me the pH. That is if I know the concentration of the salt I can simply calculate the pH and check whether it is correct or wrong.

So, I do not have to go to a laboratory to check the pH, if you are tell me that you have dissolved so much salt, we a salt of strong acid and weak base. So, it is a another way of putting it, then I have case the 3; that is weak acid and weak base, here also I can write pH is nothing but pK_a logarithm of the ratio of salt to acid. Weak acid weak base you know or salt to acid that will give me pOH. That is just like pH we can write pOH and pK_b , if I know I can write pOH find out what is pOH whether it is 9 or 8 or something like that.

(Refer Slide Time: 34:59)

Hydrolysis

The equilibrium between hydrogen and OH^- in water can be written as

The A^- ions will react with H^+ ions present in water to produce

Since part of H^+ ions are consumed, $[\text{H}^+]$ ion concentration will decrease disrupting the equilibrium in eqn 1. To compensate for this decrease more water will dissociate producing H^+ and OH^- ions. Since OH^- ions increase the solution becomes more alkaline. Hence we can write

So, we are going to discuss about Hydrolysis. What is Hydrolysis? I am writing H_2O plus has H plus and OH minus and I can write a salt MA as M plus and A minus M represents metal, it maybe sodium potassium or anything A maybe acetic acid or any other salt. So, the A minus ions will react with H plus to give me H A, since part of H plus ions are consumed H plus ion concentration will decrease, part of H plus is consumed so, HA is 1 this is undissociated so, the pH should decrease.

So, disrupting the equilibrium in equation 1; so, to compensate for this decrease more water will dissociate producing H plus and OH minus ions. Since that Le Chatelier principle again since OH minus ions decrease the solution increase the solution, solution becomes more alkaline. Hence we can write A minus plus H_2O going to OH minus plus HA. The reverse reaction in this case is more predominant that is what I am trying to drive.

(Refer Slide Time: 36:25)

The interaction between the ions of the salt and ions of water is called as hydrolysis. Hydrolysis of weak acid and strong base produces a weak acid or a weak base or both a weak acid and a weak base as shown in equation 1. we can write

$$\frac{a_{\text{OH}^-} \times a_{\text{HA}}}{a_{\text{A}^-}} = \frac{[\text{OH}^-][\text{HA}]}{[\text{A}^-]} \times \frac{f_{\text{OH}^-} \times f_{\text{HA}}}{f_{\text{A}^-}} = K_h$$

K_h is known as hydrolysis constant.

The degree of hydrolysis is the fraction of each gram-molecule hydrolysed at equilibrium. Mathematically it is essentially same as dissociation constant.

$$\frac{x^2}{(1-x)^2} = \text{Degree of hydrolysis} = K_h$$

So, the interaction between the ions of the salt and ions of water is known as hydrolysis. So, the hydrolysis of weak acid and strong base produces a weak acid and or a weak base and or both a weak acid and weak base we can write a OH into a HA divided by a A minus that is concentration term this is f OH into f HA that is a activity coefficient, all these we had discussed earlier.

So, the degree of hydrolysis is the fraction of each gram molecule hydrolyzed at equilibrium this is the definition. The degree of hydrolysis is the fraction of each gram molecule hydrolyzed at equilibrium, mathematically I can write a similar expression like a dissociation constant; that is x square divided by 1 minus x or into V that is the degree of hydrolysis that is symbol is K_h .

(Refer Slide Time: 37:30)

Buffer solution

Consider a mixture of a weak base of dissociation constant K_b in which acid and its salt concentrations are equal. Hence we can write,

$$pH = pK_a + \log \frac{[\text{salt}]}{[\text{acid}]} \times K_b$$

Since $[\text{salt}]$ and $[\text{acid}]$ are equal $pH = pK_a$

Thus we add a small quantity of 0.1N acetic acid 0.1N acetic acid,

It will combine with acetate ions form undissolved acetic acid.

Similarly if we add a small concentration hydroxyl ions (OH^-) it will combine with H^+ ions to form undissolved water

So, degree of hydrolysis leads us to the situation of Buffer solutions. So, what is a buffer solution? We consider a mixture of weak acid or a weak base dissociation constant pH is equal to pK_a plus log of salt or acid into K_b . So, salt and acids are equal pH is equal to pK_a . So, we add a small quantity of 0.1 normal acetic acid, then K_a plus CH_3COO^- will become CH_3COOH here it should be H^+ plus please correct this. Here it should be H^+ plus.

So, it will combined with acetate ions from undissolved acetic acid. Similarly, if I add a small concentration OH^- ions it will combined with H^+ plus to form undissolved water. So, in affect the pH remains unaffected.

(Refer Slide Time: 38:51)

In either case the pH of the solution, will not change appreciably, since concentration of the acid will remain unchanged. Such solutions are called buffer solutions.

Buffer capacity is maximum when acid : salt is 1:1

For acid : salt, 1:3, $\text{pH} = \text{pK}_a - \log 1/3 = \text{pK}_a - 0.48$

For acid : salt, 3:1, $\text{pH} = \text{pK}_a + \log 1/3 = \text{pK}_a + 0.48$

The approximate pH range for buffer capacity is 1:10 of acid or salt

Buffer solutions find many applications in chemical preparations, quantitative analysis, precipitations, electro depositions etc.

So, in either case the pH of the solution will not change appreciably, since the concentration of the acid will remain unchanged such solutions are called buffer solutions. So, buffer capacity is maximum when acid to salt is 1 is to 1 ratio; for acid to salt 1 is to 3 pH is given by this expression $\text{pK}_a - \log$ of one third for acids it is $\text{pK}_a + 0.48$.

And the appropriate approximate pH range for buffer capacity is if you add 10 times acid or salt buffer solutions find the pH will not change appreciably. The buffer solutions find many applications in chemical preparations, quantitative analysis, precipitations, electro deposition etcetera. So, here we come to the end of our general chemistry introduction to electrochemical techniques. And from the next class we will start looking at the electrochemical techniques in particular.

So thank you very much. We will continue our discussion in the next class.
