Lecture – 13
Interaction Hamiltonian – Part 3

Hello, welcome to lecture number 13 of the quantum mechanics and molecular spectroscopy course. We will quickly go through the contents of lecture number 12 before we proceed with lecture number 13.

(Refer Slide Time: 00:49)

$$F_L = q(E + v \times B) \Rightarrow \text{Lorentz force}$$

↑ ↑ ↑
charge of the particle electric field magnetic field
velocity of the particle.

$$F = m \cdot a = \frac{d}{dt} \hat{p}$$
$$\hat{p}' = (\hat{p} - qA)$$

↑ ↑
original momentum vector field.

$$\hat{H} = \frac{\hat{p}'^2}{2m} + V(x)$$

In the last class, I told that a charge particle when placed in electromagnetic radiation or the light will experience what is known as Lorentz force okay and Lorentz force $F_L = q$ times $E + vB$ okay, where q is the charge of the particle, so this is the Lorentz force okay where q is the charge of the particle and E is the electric field, B is the magnetic field and v is the velocity.

And this in terms of classical mechanics force is given as mass into acceleration which could be written as d by dt of momentum okay. So, we use the analogy of this and converted the momentum P or P prime = $P - qA$ where P is the original momentum and A is the vector field okay. Having done this, then we cast the total Hamilton H as P prime square by two $2m + V$ of x , we consider only in the V_x direction.

(Refer Slide Time: 03:01)

$$\hat{H}'(t) = \frac{i\hbar q}{m} \hat{A} \cdot \nabla \quad -i\hbar \nabla = \hat{p}$$

$$\Downarrow$$

$$\hat{H}'(t) = \frac{+q E_0}{\omega m} \cos(\omega t) \hat{\epsilon} \cdot \hat{p}$$

$$= \frac{+q}{\omega m} \cos(\omega t) E_0 \hat{\epsilon} \cdot \hat{p}$$

$$\hat{H}'(t) = \frac{q}{\omega m} \cos(\omega t) \hat{E} \cdot \hat{p} \quad \text{--- one charge}$$

$$\hat{H}'(t) = \frac{+E_0}{\omega} \cos(\omega t) \sum_n \frac{q_n}{m_n} \hat{\epsilon} \cdot \hat{p}_n$$

Collection of charges

After doing the necessary math, we came across the equation in which H prime of t is given by $i\hbar q$ by $m A \cdot \nabla$ okay that is your but $-i\hbar \nabla$ is nothing but operator P okay. Then we could condense this equation to finally H prime of $t = -q E_0$ by $\omega m \cos \omega t E \cdot P$ okay. So, this could be written as $-q$ by, sorry plus, there was a $+$ $\omega m \cos \omega t$ and you know E_0 into $E \cdot P$ and this E_0 into E can be written as E .

So q by $\omega m \cos \omega t E \cdot P$. So, this is H prime of t okay, but in the case of particles which are atom or a molecule which has large number of particles, so which all of the charge particles will interact with the light. So this H prime t , this is for one charge, and when for collection of charges will turn out to be minus, sorry $+ E_0$ by $\omega m \cos \omega t$ $\sum_n \frac{q_n}{m_n}$.

Sorry this is not needed because m is changing, going to be different for different particles $m_n P$ okay because p is going to be momentum of the associated particle. So this is for collection of charges okay. So, we will start this lecture with this equation.

(Refer Slide Time: 05:57)

$$\hat{H}'(t) = \frac{E_0}{\omega} \cos(\omega t) \sum_n \frac{q_n}{m_n} \hat{\epsilon} \cdot \hat{p}_n$$

q_n, m_n, \hat{p}_n are charge, mass, momentum of the n th particle

$$P_f(t) = \frac{1}{\hbar^2} \left| \int_0^t e^{-i\omega_f t'} \langle f | \hat{H}'(t') | i \rangle dt' \right|^2$$

$$\langle f | \hat{H}'(t) | i \rangle = \langle f | \frac{E_0}{\omega} \cos(\omega t) \sum_n \frac{q_n}{m_n} \hat{\epsilon} \cdot \hat{p}_n | i \rangle$$

So what we have? At the end of the last class we had just H' of $t = E_0$ by $\omega \cos \omega t \sum_n \frac{q_n}{m_n} \epsilon \cdot p_n$ where q_n, m_n, p_n are charge, mass, momentum of the n th particle okay. So this is what we have. Now if you go back to the coefficient or the probability, your P of t that is the probability of $f = 1$ over \hbar square integral or modulus of integral 0 to t prime e to the power of $-i \omega_f t$ integral f prime of t i dt modulus square okay.

That means we still have to evaluate this integral f H' prime of t i . So unless this integral is evaluated, of course you cannot evaluate this P of t okay. Now to evaluate this integral, now we know the Hamiltonian, so we need to plug in this value of H' prime of t okay. So your integral f H' prime of t i is given by f E_0 by $\omega \cos \omega t \sum_n \frac{q_n}{m_n} \epsilon \cdot p_n$ i . So this is the integral that I need to evaluate okay.

(Refer Slide Time: 08:48)

$$\langle f | \hat{H}'(t) | i \rangle = \frac{E_0}{\omega} \cos(\omega t) \langle f | \sum_n \frac{q_n}{m\omega} \hat{p}_n | i \rangle$$

Commutator of operators \hat{r} and \hat{H}_0

$$[\hat{r}, \hat{H}_0] = \frac{i\hbar}{m} \hat{p}$$

\hat{r} and \hat{H}_0

$$\hat{r} = r, \quad \hat{H}_0 = -\frac{\hbar^2}{2m} \nabla^2 + V(r) = -\frac{\hbar^2}{2m} \nabla_r^2 + V(r)$$

$$[\hat{r}, \hat{H}_0] f(r) = r \left(-\frac{\hbar^2}{2m} \nabla^2 \right) f(r) - \left(-\frac{\hbar^2}{2m} \nabla^2 \right) r f(r)$$

$$= -\frac{\hbar^2}{2m} r \nabla^2 f(r) + \frac{\hbar^2}{2m} \left\{ 2 \nabla f(r) + r \nabla^2 f(r) \right\}$$

$$= -\frac{\hbar^2}{2m} r \nabla^2 f(r) + \frac{\hbar^2}{2m} \nabla^2 f(r) + \frac{\hbar^2}{2m} r \nabla^2 f(r)$$

$$= \frac{\hbar^2}{m} \nabla f(r) = \frac{i\hbar}{m} \frac{\partial}{\partial r} f(r)$$

$$[\hat{r}, \hat{H}_0] = \frac{i\hbar}{m} \hat{p}$$

Now, I am going to slightly rewrite this equation or this integral $\langle f | \hat{H}'(t) | i \rangle = \text{now } E_0 \text{ by } \omega \cos \omega t$. I will take it outside integral f because E_0 is a constant, ω is a constant, $\cos \omega t$ is a constant as far as this integral is concerned f because f and i are the eigen function of the time-independent Hamiltonian okay f times sigma over n q_n by $m\omega$ epsilon P_n okay.

Now to begin with we will start with slightly some other equation. So if I take a quantity called r , H_0 commutator, that is the commutator of operators r and H_0 okay, right. Now this can be evaluated at this commutator r , H_0 can be evaluated to be $i\hbar \hat{p}$ by m okay. Now, I am going to take a small detour and try to evaluate this commutator, but always remember the commutators are evaluated with respect to some function.

So if there is an r operator and there is H_0 operator okay, H_0 is along the direction of r , so this will be equal to $-\hbar^2$ by $2m$ d^2 by dr^2 with some potential V of r okay that is your H_0 okay. Now, then all of this will act on a function f of r . So let us evaluate the commutator. By the way this is also called $-\hbar^2$ by $2m$ ∇^2 + V of r okay. So now what you have to evaluate?

You have to evaluate r , H_0 commutator with respect to f of r function okay. So this will be equal to r times $-\hbar^2$ by $2m$ ∇^2 f of r minus $-\hbar^2$ by $2m$ ∇^2 $r f$ of r okay. Now take the first term, so that this is going to be $-\hbar^2$ by $2m$ because that is constant r time ∇^2 f of r okay. Now the second one is this is minus of this minus, this will be plus, \hbar^2 by $2m$ ∇^2 $r f$ of r okay.

Now if you take this, I am just going to evaluate this, so $\nabla^2 r f(r)$ this is equal to, but ∇ is nothing but ∇ , ∇^2 , so that is nothing but ∇ of $\nabla r f(r)$. So one can first evaluate this, so this is nothing but ∇ times, now this is a differential, ∇ is nothing but d by dr , so the differential function, so first acts on r so it will give you 1, so we will get $f(r)$ okay.

Now second this will act on $\nabla f(r)$ okay, so what you will get is $+r$ times $\nabla f(r)$. Now again the second ∇ acts on it or the second differential acts on, so you will get $\nabla f(r)$ plus, now you have again a function, so this is one function and this is another function ∇ of r is 1 okay. So we will get $\nabla f(r)$ because that is $1 + \nabla$ acting on $\nabla f(r)$ giving me r into $\nabla^2 f(r)$ okay.

So, now I am going to plug this in here, what you will get is, so what I am evaluating? I am evaluating $r H_0$ commutator. So this is equal to $-\hbar^2$ by $2m$ $\nabla^2 r f(r) + \hbar^2$ by $2m$, what do you have, $\nabla f(r) \nabla f(r)$, $2 \nabla f(r) +$ this is $r \nabla^2 f(r)$. Now if I expand this, this will be $-\hbar^2$ by $2m$ $\nabla^2 r f(r) +$ this 2 and this 2 will get canceled, we will get \hbar^2 by $2m$ $\nabla f(r) + \hbar^2$ by $2m$ $r \nabla^2 f(r)$.

I will see that this term and this term will get canceled. So this will be equal to \hbar^2 by $2m$ $\nabla f(r)$. So, this is nothing but this is $= -i\hbar$, so there is no 2 here just m , by m multiplied by $i\hbar$, so this is $+i - i\hbar$ by, so minus i square, minus into minus, plus $i\hbar$ $\nabla f(r)$, sorry finally you do not have $f(r)$ because it is evaluated with respect to $f(r)$. So then you have to put $f(r)$ here as well.

So then your r , but this is nothing but P of r okay. So what you get r , H commutator will be equal to $i\hbar$ by m P okay. So, because now I want to use this P operator here okay.

(Refer Slide Time: 17:32)

$$\begin{aligned}
\langle f | \hat{H}'(t) | i \rangle &= \frac{E_0 \cos(\omega t)}{\omega} \langle f | \sum_n \frac{q_n}{m} \hat{\epsilon} \cdot \mathbf{p}_n | i \rangle \\
[\mathbf{r}, \hat{H}^0] &= \frac{i\hbar \mathbf{p}}{m} \\
&= \frac{E_0 \cos(\omega t)}{\omega} \langle f | \sum_n q_n \hat{\epsilon} \cdot \frac{\mathbf{p}_n}{m} | i \rangle \\
&= \frac{-i E_0 \cos(\omega t)}{\hbar \omega} \langle f | \sum_n q_n \hat{\epsilon} [\mathbf{r}_n \hat{H}^0] | i \rangle \\
&= \frac{-i E_0 \cos \omega t}{\hbar \omega} \langle f | \sum_n (q_n \hat{\epsilon} \cdot \mathbf{r}_n \hat{H}^0 - q_n \hat{\epsilon} \cdot \hat{H}^0 \mathbf{r}_n) | i \rangle \\
&= \frac{-i E_0 \cos \omega t}{\hbar \omega} \left\{ \langle f | \sum_n q_n \mathbf{r}_n \hat{H}^0 | i \rangle - \langle f | \sum_n q_n \hat{H}^0 \mathbf{r}_n | i \rangle \right\} \\
&= \frac{i E_0 \cos \omega t}{\hbar \omega} \left\{ E_i \langle f | \sum_n q_n \mathbf{r}_n | i \rangle - E_f \langle f | \sum_n q_n \mathbf{r}_n | i \rangle \right\}
\end{aligned}$$

So let us continue. So what was the equation that we had, this one okay. So $f | H' \text{ of } t | i = E_0 \text{ by } \omega \cos \omega t$ acting on $f | \sum_n \frac{q_n}{m} \hat{\epsilon} \cdot \mathbf{p}_n | i$ and we found that \mathbf{r}, H^0 commutator is equal to $i\hbar \mathbf{p}$ by m okay. Now what I am going to do this? So I am going to plug in it here. So this now will be equal to $E_0 \text{ by } \omega \cos \omega t f | \sum_n \frac{q_n}{m} \hat{\epsilon} \cdot \mathbf{p}_n | i$ okay. So $\mathbf{p}_n \text{ by } m$ is i .

So this is nothing but $E_0 \text{ by } \omega \cos \omega t$, so $i\hbar$ go on the other side that will i will become $-i\hbar$. So you have $\hbar -i$ that is what you get okay. $\sum_n f | \sum_n \frac{q_n}{m} \hat{\epsilon} \cdot \mathbf{p}_n | i$ okay. So that is the new Hamiltonian when you have plugged in this value. So this will be equal to $-i E_0 \text{ by } \hbar \omega \cos \omega t$ into f okay. Now let us expand this commutator.

So this will be $\sum_n \frac{q_n}{m} \hat{\epsilon} \cdot \mathbf{p}_n H^0 - \sum_n \frac{q_n}{m} \hat{\epsilon} \cdot \mathbf{p}_n H^0$ okay, I have just expanded this commutator \mathbf{r}, H^0 because that it will be $\mathbf{r} H^0 - H^0 \mathbf{r}$. So this will be equal to $-i E_0 \text{ by } \hbar \omega \cos \omega t$ okay. I will write it as two. Because there are 2 terms here, we can write it as 2 separate integrals. So $f | \sum_n \frac{q_n}{m} \hat{\epsilon} \cdot \mathbf{p}_n | i$ okay because \mathbf{r} is just, now $\sum_n \frac{q_n}{m} \hat{\epsilon} \cdot \mathbf{p}_n H^0$ acting on $i - f | \sum_n \frac{q_n}{m} \hat{\epsilon} \cdot \mathbf{p}_n | i$ okay.

So now this H^0 will act on i and give me $E_i i$. So this will now be equal to $i E_0 \text{ by } \hbar \omega \cos \omega t$ this H^0 acting on i give me $E_i i$, so $E_i f$ because E_i is a number $f | \sum_n \frac{q_n}{m} \hat{\epsilon} \cdot \mathbf{p}_n | i$ okay. Now this H^0 will act on the other side because you know H^0 is a Hermitian operator and we know the turnover rule. So if I use turnover, this H^0 can act on f and give me E_f okay, complex conjugate of it.

But energies are always real, so complex conjugate of E_f star will be only E_f . So this will be $-E_f$ integral f sigma over n $q_n r_n$ i . Now you will see the integral in both cases is the same.

(Refer Slide Time: 23:54)

$$\begin{aligned}
 \langle f | H'(t) | i \rangle &= \frac{-i E_0}{\hbar \omega} \cos(\omega t) \left\{ (E_i - E_f) \langle f | \sum_n q_n r_n \hat{z} | i \rangle \right\} \\
 &= \frac{-i E_0}{\hbar \omega} \cos(\omega t) \hbar \omega_{if} \langle f | \sum_n q_n r_n \hat{z} | i \rangle \quad E_i - E_f = \Delta E_{if} = \hbar \omega_{if} \\
 &= -i E_0 \cos(\omega t) \left(\frac{\hbar \omega_{if}}{\hbar \omega} \right) \langle f | \sum_n q_n r_n \hat{z} | i \rangle \\
 \langle f | H'(t) | i \rangle &= -i E_0 \cos(\omega t) \left(\frac{\hbar \omega_{if}}{\hbar \omega} \right) \langle f | \mu_z | i \rangle
 \end{aligned}$$

Selection rules: \Leftrightarrow { projection of dipole-moment along the electric field vector } $\sum_n q_n r_n = \mu$

So essentially your $f | H'(t) | i$ can be written as $-E_0$ i by $\hbar \omega_{if} \cos \omega t$ into $E_i - E_f$ into integral f sigma over n $q_n r_n$ \epsilonpsilon divided by i okay. Now what is $E_i - E_f$, E_f sorry, $E_i - E_f = \Delta E_{if}$, so this is nothing but $\hbar \omega_{if}$. So this is nothing but this is equal to $-i E_0 \hbar \omega_{if} \cos \omega t$, this will be $\hbar \omega_{if}$ if integral f sigma over n $q_n r_n$ \epsilonpsilon i okay.

Now this $\hbar \omega_{if}$ and this $\hbar \omega_{if}$ will get canceled, so what you will get is this $-i E_0 \cos \omega t$ ω_{if} by ω_{if} , so this is very important term okay remember, and f sigma over n $q_n r_n$ i . Now for if there are charges like this distributed over some this one okay, so this is charge q_1 , this is charge q_2 , this is charge q_3 , q_4 , q_5 , q_6 , q_7 , q_8 , q_9 , q_{10} , this is my center q_{11} and then you have radiuses r_1 , r_2 , r_3 , r_4 , r_6 , r_{11} , r_{10} , etc.

So what is this if I take, so this is a product of q and r_n sum over okay. If you have charges distributed like that that will give you the dipole moment. So for n charges sigma over n $q_n r_n$ should be equal to μ that is the dipole moment of the molecule okay. So that is nothing but is equal to μ that is the dipole moment of the molecule okay. So that is nothing but is equal to $-i E_0 \cos \omega t$ ω_{if} by ω_{if} $f \mu \epsilonpsilon$ i okay. Now, what is $\mu \cdot \epsilonpsilon$ or $\mu \epsilonpsilon$?

μ epsilon simply means that the μ has to have a dot product with along to the epsilon that is the electric field vector okay. So that is given by this equation. Now, one could understand okay if you forget these pre factors, this integral depends on the dipole moment of the atom or the molecule okay. By the way, dipole moment of atom I do not know because its permanent dipole moment is 0.

But dipole moment is not permanent dipole moment. You must understand μ is not equal to μ_0 , we will come to that it later sometime, but essentially the initial and final states will couple okay with respect to the projection of the dipole moment along the electric field vector. So this is nothing but the projection of dipole moment along the electric field vector okay.

And the projection of the dipole moment along the electric field vector determines the selection rules and this will lead to selection rules okay. We will stop it here for this class and continue in the next lecture.
