Lecture No -28
Rotational Selection Rules

Hello, welcome to lecture number 28 of the course quantum mechanics and molecular spectroscopy. In the last class, we are looking at the transition moment integral for the rotational transitions.

(Refer Slide Time: 00:27)

So T M I was equal to $Y J \text{ prime } M \text{ prime } \theta \phi \mu_0$ and, μ it is $Y J \text{ double prime } M \text{ double prime } \theta \phi$. Now I told you that $Y J \text{ prime } M \text{ double prime}$, the double prime will belong to the initial state and $Y J \text{ prime } M \text{ prime}$ will belong to final state. So single prime represents a final state and double prime represents a initial state. Now, of course if you consider the molecule A B and this is some direction r , then it could be, r could be pointing in any direction along x, y, z .

So your μ_0 will be equal to μ_0 along x axis into i vector which is a unit vector along x axis + μ_0 into y along y axis where j is the unit vector + μ_0 z to k vector that is the unit vector. So this i, j, k are unit vectors along x, y, z axis. Now, so your TMI will now become $Y J M \theta \phi$

$\mu_0 x \hat{i} + \mu_0 y \hat{j} + \mu_0 z \hat{k}$ along the electric field vector $\hat{Y} \hat{J} \text{ double prime } M \text{ double prime}$ theta and phi.

Now the problem here is these are in Ys, these are in spherical polar coordinates and these are in Cartesian coordinates. So one has to express your μ_0 in terms of Cartesian, spherical polar coordinates.

(Refer Slide Time: 03:49)

$$\mu_0 = \mu_{0x} \hat{i} + \mu_{0y} \hat{j} + \mu_{0z} \hat{k}$$

$$= \mu_0 \left[\sin\theta \cos\phi \hat{i} + \sin\theta \sin\phi \hat{j} + \cos\theta \hat{k} \right]$$

$$\begin{cases} x = r \sin\theta \cos\phi \\ y = r \sin\theta \sin\phi \\ z = r \cos\theta \end{cases}$$

μ_0 in terms of spherical polar coordinates.

$$TMI = \mu_0 \left\langle Y_{J'}^m(\theta, \phi) \left[\sin\theta \cos\phi \hat{i} + \sin\theta \sin\phi \hat{j} + \cos\theta \hat{k} \right] Y_{J''}^m(\theta, \phi) \right\rangle$$

$$TMI = \mu_0 \int_{\theta, \phi} Y_{J'}^m(\theta, \phi) \left[\sin\theta \cos\phi \hat{i} + \sin\theta \sin\phi \hat{j} + \cos\theta \hat{k} \right] Y_{J''}^m(\theta, \phi) \sin\theta d\theta d\phi$$

Volume element in polar coordinates for $\theta, \phi = \sin\theta d\theta d\phi$

Therefore one can write μ_0 is equal to μ_0 into $x \hat{i} + \mu_0 y \hat{j} + \mu_0 z \hat{k}$ will be equal to μ_0 into, x is nothing but $\sin\theta \cos\phi$ in spherical polar coordinates x is equal to $\sin\theta \cos\phi$, y is equal to $\sin\theta \sin\phi$ and z is equal to $\cos\theta$, so this is from the conversion of spherical polar coordinates into Cartesian coordinates, $\cos\phi$ into $\hat{i} + \sin\theta \sin\phi \hat{j} + \cos\theta \hat{k}$. Now this is the modified μ_0 , μ_0 in terms of spherical polar coordinates.

Now therefore your TMI can now be written as $\hat{Y} \hat{J} \text{ prime } M \text{ prime } \theta \text{ phi}$. So your μ_0 is now $\sin\theta \cos\phi + \sin\theta \sin\phi \hat{j} + \cos\theta \hat{k}$, whole thing along the $\epsilon \hat{Y} \hat{J} \text{ prime } M \text{ prime } \theta \text{ and } \phi$. So that is your transition moment integral. Now, but this integral has to be integrated over spherical polar coordinates. So if I write the integral, this will become integral, actually double integral one over θ and one over ϕ .

Y J prime M prime theta and phi of theta and phi deployed by sin theta cos phi i + sin theta sin phi j + cos theta k Y J double prime M double prime theta and phi sin theta d theta d phi. Because the volume element in polar coordinates for theta and phi will be volume element in polar for theta, phi will be equal to sin theta d theta d phi. So we have these transition momentum integral will look like this.

So this transient moment integral of course you know depending on whether your dipole moment is along x axis or y axis or z axis and the electric field could be along x axis, y axis, z axis, you will get 3 integrals.

(Refer Slide Time: 08:21)

$$T_{fi} = \mu_0 \int_0^\pi d\theta \int_0^{2\pi} d\phi \int Y_{J_1}^{M_1}(\theta, \phi) \begin{cases} \sin\theta \cos\phi i \\ \sin\theta \sin\phi j \\ \cos\theta k \end{cases} Y_{J_2}^{M_2}(\theta, \phi) \sin\theta d\theta d\phi$$

$$\hookrightarrow T_{fi} = \mu_0 \left\{ \int_0^\pi \int_0^{2\pi} Y_{J_1}^{M_1}(\theta, \phi) Y_{J_2}^{M_2}(\theta, \phi) \sin^2\theta \cos\phi d\theta d\phi \right. \\ \left. + \int_0^\pi \int_0^{2\pi} Y_{J_1}^{M_1}(\theta, \phi) Y_{J_2}^{M_2}(\theta, \phi) \sin^2\theta \sin\phi d\theta d\phi \right. \\ \left. + \int_0^\pi \int_0^{2\pi} Y_{J_1}^{M_1}(\theta, \phi) Y_{J_2}^{M_2}(\theta, \phi) \cos\theta \sin\theta d\theta d\phi \right\}$$

Out of the three integrals at least one of the integrals must be non-zero

So, TMI will be now be equal to, i will take mu0 as common, by the way there is a mu0, there is a mu0 that I forgot because you know everything this multiplier, so mu0, so this will be equal to mu0 into integral phi d phi integral theta, phi will go from 0 to 2 pi, theta will go from 0 to pi, Y J prime M prime theta and phi will have 3 integrals, one will be sin theta cos phi, there is an i but i is inconsequential;

sin theta sin phi j and cos theta whole thing multiplied by Y J M double prime sin theta d theta. Now what I am going to do is that, I am going to rewrite this as 3 separate integrals so that will be equal to TMI mu0 equals to phi 0 to 2 pi, theta is equal to 0 to pi Y J prime M prime theta phi Y J double prime M double prime theta phi, this sin theta d theta then theta will be sin square theta,

$\cos \phi \, d\theta \, d\phi$. So that is one integral + μ_0 will be ϕ theta 0 to π 0 to 2π Y J prime M prime theta phi Y J double prime M double prime theta phi.

This is $\sin \theta$, that $\sin \theta$, again $\sin^2 \theta$, $\sin \phi \, d\theta \, d\phi$ + the third integral ϕ is equal to 0 to 2π , θ is equal to 0 to π , Y J prime M prime theta phi Y J double prime M double prime theta phi, this is $\cos \theta$, that is $\sin \theta$, so $\cos \theta \sin \theta \, d\theta \, d\phi$. So you will have 3 integrals. Now the for the transient moment integral to become non zero or have a selection rule, any one of the integrals must be non zero. Out of the 3 integrals at least 1 of the integrals must be non zero.

(Refer Slide Time: 12:57)

$TMI = \mu_0 \int_0^\pi \int_0^{2\pi} Y_l^m(\theta, \phi) Y_{l'}^{m'}(\theta, \phi) \left\{ \begin{matrix} \sin \theta \cos \theta \\ \sin \theta \sin \theta \\ \cos \theta \end{matrix} \right\} \sin \theta \, d\theta \, d\phi$

$\Delta J = \pm 1 \quad \Delta M = 0 \Rightarrow$ Selection Rule

Spherical harmonics HOMR-work To evaluate

$\Delta J = \pm 1$ $J=0 \rightarrow J=1$ allowed $E_{n+1} = h^2 J(J+1)$
 $J=1 \rightarrow J=2$ allowed

$(0 \rightarrow 1) \Delta E_{n+1} = E_{J=1} - E_{J=0} = h^2(2 - 0) = 2h^2$

$(1 \rightarrow 2) \Delta E_{n+1} = E_{J=2} - E_{J=1} = 6h^2 - 2h^2 = 4h^2$

$(2 \rightarrow 3) \Delta E_{n+1} = E_{J=3} - E_{J=2} = 12h^2 - 6h^2 = 6h^2$

Now when you evaluate these integrals in terms of spherical harmonics, so your transient moment integral TMI in a compact form will be μ_0 integral over ϕ integral over θ Y J prime M prime theta phi Y J double prime M double prime theta phi multiplied by $\sin \theta \cos \phi \sin \theta \sin \phi \cos \theta$ into $\sin \theta \, d\theta \, d\phi$. Now one of this integral must be non, so there are 3 integrals 1, 2 and 3 and one of them must be non zero;

And when you evaluate what appears is you get ΔJ is equal to ± 1 and ΔM is equal to 0. So that is the selection rule. So essentially one has to put the in a wave functions or these YJM are nothing but your spherical harmonics and once you plug in the spherical harmonics one can

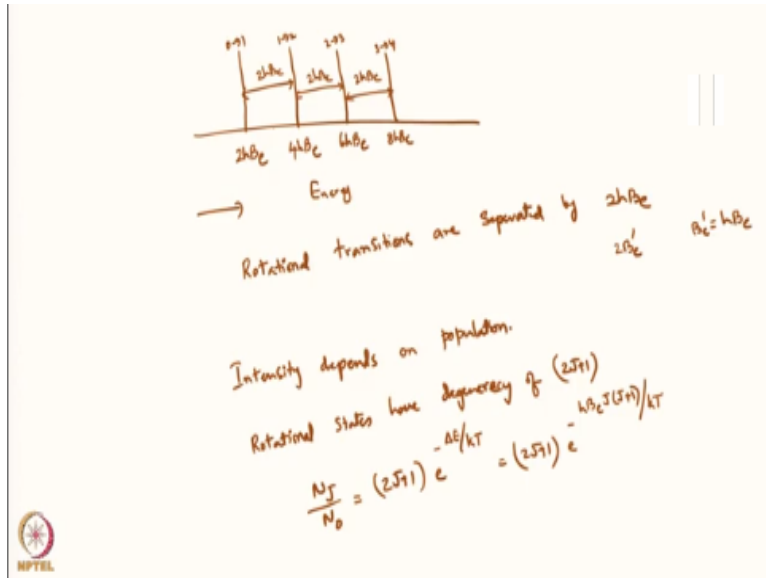

evaluate this integral. Evaluation of this integral is tedious but not, it is possible to evaluate, it will take about no an hour or so to evaluate each of these integrals.

So which is a, which you can do it as a homework. Let us just look at 1 integral, 2 integrals. So at the end when you have that, when you have the selection, so what you will get is ΔJ is equal to ± 1 , that means transition from J is equal to 0 to J is equal to 1 will be allowed. Similarly from J is equal to 1 to J is equal to 2 will be allowed etcetera and your ΔE rotation will be equal to, what was our ΔE ? E rotation, E rotation was nothing but $h B J$ into $J+1$.

You can go back and check or we call it as B equilibrium. So this will be now equal to $E J$ is equal to 1 $- E J$ equal to 0. So if I do that, this will be $h B e$, when J is equal to 1 you will get 1 into $1+1$ 2, so this will be 2^- , when J is equal to 0, this will go to 0, so that will be 0, that will be nothing but $2h B e$. So similarly if you have ΔE rotation is equal to $E J$ is equal to 2 $- E J$ is equal to 1. So this will be equal to, when J is equal to 2, this will be $2+1$ 3, 3 into 2, 6, so this will be $6h B e - 2h B e$, so this is equal to $4h B e$.

Similarly when you have ΔE rotation $E J$ is equal to 3 $- E J$ is equal to 2, I am looking for, so this is from 0 to 1, this is from 1 to 2 and this is from 2 to 3, so when you have 3, this will be $3+1$ 4, 4 into 3; 12, so this will be $12h B e^-$, this is when is equal 2 is a $6h B e$, so the $6h B e$, so this will be nothing but $6h B e$. Now you can see a geometric progression. This is $2h B e$, this is $4h B e$, so this is $6h B e$.

(Refer Slide Time: 17:54)

So what appears is that, so when you have this one, so the first line will come at $2h B e$, the second line will come at $4h B e$ and third line will come at $6h B e$. Now we will see the difference between these lines and it is also possible to show that it is the fourth line will come at $8h B e$. So this is nothing but the energy. So this is will be from 0 to 1, this will be from 1 to 2, this will be from 2 to 3 and this will from 3 to 4, value of J s.

Now if you have this, now this will again be, this is $2h B e$, this also $2h B e$, this also $2h B e$. So the rotational transitions are separated by $2h B e$. By the way in some text books, this also written as this h is absorbed into $B e$ and then you can also you also get as $2 B e$, let us say $B e$ prime, where $B e$ prime is equal to $h B e$. So they are equally spaced rotational lines and each of them will be a geometric progression.

Now when you have such rotational spectrum, so you will think that you will get a rotational spectrum which is like this, but unfortunately the rotational spectrum does not look like this. What it looks is slightly different. Now this rotational spectrum will also, the intensity of the transition will also depend on the population. Now you know rotational states have a degeneracy of $2 J+1$. So the zeroth state, that is J is equal to 0 state has degeneracy of 1 is non degenerate while J is equal to 1 state has a degeneracy of 3 and so on, that $2 J+1$.

So now what happens is that your N_J by N_0 will be equal to population, will be equal to $2J+1$ multiply e to the power of $-\Delta E$ by $K T$. So this is nothing but $2J+1$, ΔE , now if I want to go from J into $J+1$, J is or 0 to J to the power of $-h B_e J$ into $J+1$ divided by $K T$, where T is your absolute temperature and K is the Boltzmann constant.

(Refer Slide Time: 22:05)

So in that scenario, now if I plot N_J by N_0 as a function of J , then this will look something like this. So this is 1 and this value I will call it as J_{max} , so this will be 0, 1, 2, in this case 3 could be J_{max} , 4, 5, 6. 3 happens to be J_{max} but this J_{max} will depend on two things. So J_{max} will depend on one temperature and two rotational constant or value of B_e . N_J by N_0 is given by $2J+1$ into e to the power of $-h B_e J$ into $J+1$ by $K T$.

Now you see this is e to the power of $-B_e$, so as B_e increases, this decreases and as so J_{max} decreases as B_e increases. Also J_{max} increases as T increases. So depending on the molecule and the temperature the J_{max} will keep changing because for different values of temperature and the rotational constant B_e will have different J_{max} . Therefore the rotational spectrum will look like, something like that.

So it will have intensities which will go up and come down something very similar to this. So this is 1, 0 to 1, 1 to 2, 2 to 3, 3 to 4, 4 to 5, 5 to 6, 6 to 7, 7 to 8, 8 to 9. So this profile will reflect population of rotational states. Now there is one more thing, we have to say that ΔJ is equal

to $+1$. So this is all will reflect to ΔJ is equal to $+1$, so increasing. But there is a another set of lines which is, which will have a mirror image, will go like that, will come to have ΔJ is equal to -1 .

So this will be from 1 to 0 , 2 to 1 , 3 to 2 , 4 to 3 etcetera. So there will be a mirror image. So this is called P branch, this is called R branch. And there is something right in the middle called Q branch where is ΔJ is equal to 0 is called Q branch. But this line is missing in the rotational spectrum. So that is 0 to 0 , 1 to 1 , 2 to 2 , so those transitions are not allowed. So they will be missing. So your rotation spectrum will look like this. We will stop it here and continue in the next lecture, thank you.
