

## Spectroscopic Techniques for Pharmaceutical & Biopharmaceutical Industries

Prof. Shashank Deep

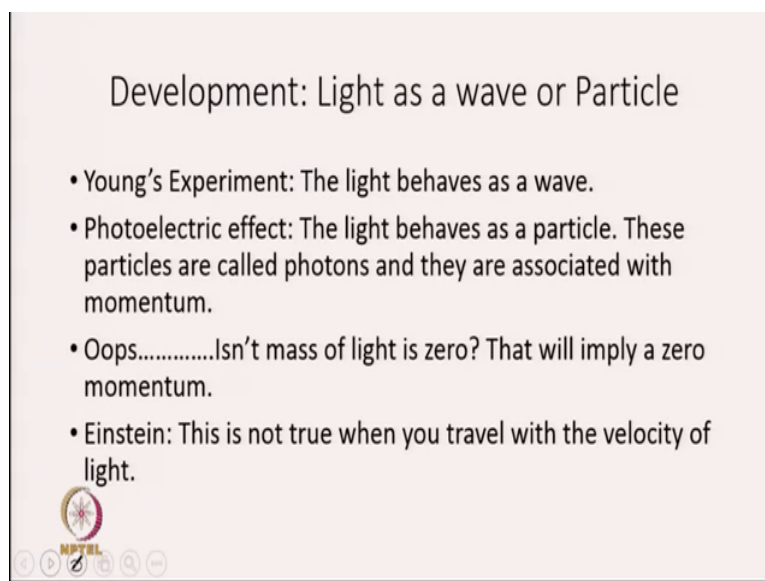

Department of Chemistry, Indian Institute of Technology, Delhi

Lecture 04:-

### Introduction to Spectroscopy 4

Hello students welcome back we will continue to discuss basics of spectroscopy. So what we discussed in the last two lectures is that light can behave as both wave or a particle.

(Reference Slide Time: 00:-56)

Development: Light as a wave or Particle

- Young's Experiment: The light behaves as a wave.
- Photoelectric effect: The light behaves as a particle. These particles are called photons and they are associated with momentum.
- Oops.....Isn't mass of light is zero? That will imply a zero momentum.
- Einstein: This is not true when you travel with the velocity of light.

NPTEL

So we did see that during Young's experiment light behave as a wave so when light is passed through two pinholes a diffraction pattern was obtained which is a peculiar property of a wWave but then during the photoelectric effect what we saw is (light behaves as a particle) light behaves as a particle these particles are called photons and they are associated with momentum.

Now this was a bit surprising considering that mass of light is zero what does that mean that photon should have a 0zero momentum if photon has 0zero momentum and how we can say it is a particle. I still explained this by suggesting that momentum is not 0zero when a particle travel with the velocity of the light.

-This was very important contribution by Einstein and for that he got a Nobel Prize so Young suggested that light behaves as a wave photoelectric effect showed that light can also behave as particle and Einstein still explained this behaviour by suggesting that a particle will not have 0zero momentum when it travels with the velocity of light.

(Reference Refer Slide Time 02:54)

Momentum of a photon

$$E = mc^2 = \sqrt{p^2 c^2 + m_0^2 c^4}$$

Rest mass = 0

$$E = hv = \frac{hc}{\lambda}$$
$$p = \frac{E}{c}$$
$$\lambda = \frac{h}{p}$$

Light can behave as wave or particle depending on the experiment, and photons can have momentum.

Now, let me explain this in detail, so this is the equation given by Einstein for the energy of the particle energy is given by  $mc^2$  square and that is basically equal to a square root of  $p^2 c^2$  square plus  $m_0^2 c^4$  square.

So if rest mass is zero that is what we expect for particles like photon then this term will be zero this term will be zero what does that mean is your  $p$  will be given by  $\frac{E}{c}$ ,  $p$  will be given by  $\frac{E}{c}$ .

Now we know that  $E$  is equal to  $h\nu$  by lambda  $E$  is equal to  $\frac{hc}{\lambda}$  by lambda what does this say is that if we calculate  $E$  by  $\frac{hc}{\lambda}$  it will get  $\frac{h}{\lambda}$  by lambda will get  $h$  by lambda and just now I showed you that  $p$  is equal to  $\frac{E}{c}$  and since  $E$  by  $\frac{hc}{\lambda}$  is equal to  $\frac{h}{\lambda}$  by lambda what does that mean is lambda is equal to  $\frac{h}{p}$  or  $p$  is equal to  $\frac{h}{\lambda}$  so now momentum is not 0 it will be given by  $\frac{h}{\lambda}$  by lambda and that's how particle and wave is correlated.

So these two experiments, experiments by young an experiment done by Einstein y I steam which is photoelectric effect showed that light can behave as wave of particle depending on the experiments and photons can have momentum.

(Reference Slide Time 05:2:0354)

Development: Particle as a wave

- De Broglie: Electrons, which is supposed to be a particle, can behave as a wave, and they are associated with wavelength.
- Everything in a universe can behave as a wave or as a particle.
- Davisson and Germer: Electron diffraction experiment proved inconclusively that electrons behave as a wave.
- All the microscopic particles behave as a wave.

So till now we are talking about light now let us see what development took place on the particle front, it was De Broglie which suggested that electron which is supposed to be a particle can behave as a wave and they are associated with wavelength they are associated with wavelength.

So he thought that if light which a kind of wave can behave as a (particle), particle also should behave as a wave of it this is basically work of his PhD theory and when we will be surprised that de Broglie got Nobel Prize for his PhD work he also suggested that everything in universe can behave as a wave or as particle wave or as a particle and they this was a big statement which was proved by Davisson and Germer and Thomson.

What they saw that electron can behave as a wave by doing electron diffraction experiments and what does that mean is that electron apart from being a particle can behave as a wave and de Broglie also explained or De Broglie equation also suggest that all the microscopic particle can behave as a wave.

I discussed to you in the last lecture why a baseball cannot behave as a wave because wave length of a baseball with some velocity is very small very small whereas wavelength associated with electron is of the same order the size of atom size of atom and that is why

electrons ~~behave~~ as a wave where as baseballs do ~~not~~ behave as a wave P do ~~not~~ behave ~~as a wave either way the~~ spin does ~~not~~ behave as a way so these are the two important observations two important finding that both light and particle can behave as a wave and particle both can behave as wave or particle ~~the next important theory came about quantization of energy.~~

(Reference Refer Slide Time: 07:56)

~~The next important theory came about quantization of energy.~~ So, I discuss how the concept of quantization of energy came this scheme when people ~~tried~~ to explain blackbody radiation atomic spectra and heat capacity of mono atomic gas now what do we mean by quantization of energy it is very important to understand.

~~Quantization of energy means electrons cannot have all value of energy or electron can only have certain value of energy so here is a diagram of here is a electron distribution in a hydrogen atom.~~

~~So now you can see that electrons can have energy minus 13.6thirteen point six it can electrons of hydrogen can have energy minus 13.6thirteen point six minus 3.4three point four minus 1.5one point 5 electron volt minus 0.zero point 9 electron volt.~~

~~So in hydrogen atom electron can only exist with energy minus 13.6thirteen point six electron volt minus 3.4three point 4 electron volt and 1. point 5 electron volt and so on. It cannot take a value between minus 13.6thirteen point six electron volt and minus three point 3.4 electron volt and similarly it cannot take value between minus 3.three point 4 electron volt and minus 1.one point 5 electron volt. so electron can have certain value of energy when.~~

So electron can have certain value of energy when electron of atom of hydrogen atom has energy minus ~~13.6 thirteen point six~~ electron volt it is said to be in ground state. So if it is here then it is said to be a ground state when it has energy minus ~~3.4 point~~ 4 electron volt it is said to be in first excited state and electron cannot exist between these energy levels so it cannot exist between minus ~~13.6 thirteen point six~~ electron volt and minus ~~3.4 three point 4~~ electron volt it can be either have minus ~~13.6 thirteen point six~~ electron volt energy or minus ~~3.4 three point four~~ ~~electronight or~~ volt energy that is's what we mean by quantization of energy.

(~~ReferenceRefer~~ Slide Time: ~~-11:09~~)

Now, what is this why this is important so suppose we bombard light on and light on a hydrogen atom light can give all the energy to electron or it gave none of the energy of electron so what does that mean so if I bombard a hydrogen atom with energy 10.2 electron volt are ~~12.01 twelve point zero one~~ electron volt ~~or are~~ ~~12.75 twelve point seven five electron~~ volt it will absorb that energy but it will not absorb below 10.2 electron volt or suppose ~~11 electron volt eleven electron water~~.

~~I~~ it will only absorb energy if electron if photon have energy 10.2 electron volt ~~or are~~ ~~12.01 twelve point zero one~~ electron volt how does this 10.2 electron volt comes so this is the basically difference between these two energy levels.

~~S~~o if electron in an hydrogen atom ~~observe~~ ~~absorbe~~ 10.2 electron volt energy then it will go from ground state to first excited state ~~ground state to first excited state~~ if it absorb energy

equal to ~~12.01~~ ~~twelve point zero one~~ electron volt then it will go from ground state to second excited state.

It cannot absorb energy for example here in between so they are ~~re~~ like five point one electron volt it cannot absorb that because it cannot have energy equal to minus ~~13.6~~ ~~thirteen point six~~ electron volt plus ~~5.1~~ ~~five point one~~ electron volt it cannot have that energy and that is what we mean by quantization so if a light of 10.2 electron volt is struck that ~~atom~~ the electron will jump from ground state to first excited state.

(~~Reference~~ ~~Refer~~ Slide Time 13:16)

Now, let us go and try to understand quantization a bit more in the last slide we did see that electron absorbs light of certain energy now what we are going to see that if it absorbs light of certain energy what can happen if it tries to meet the energy.

So see here this electron takes energy and goes to suppose ~~excited~~ ~~site a~~ state of ~~6~~ ~~six~~ excited ~~state~~ ~~yesterdaof~~ ~~sixy top six~~ n is equal to 6. So it is going from n is equal to 2 energy level to n is equal to 6.

Now suppose it comes back then what happens so if suppose it comes back from 6 to ground state the energy of 4-10 nanometer will be emitted or light of 410 nanometer will be emitted if he comes back from 5 to n is equal to 2 then for 434 nanometer will be emitted

If it comes from 4 to your n is equal to 2 then your 486 nanometer light will be emitted and when it comes from 3 to 2 656 nanometers light will be emitted so a ~~partic~~ ~~particulare~~ light will be emitted what you can see here is that this all wavelength belongs to this all

wavelength belongs to your visible region visible region and this is well known ~~bom~~ber series.

~~so~~So in ~~bombers~~ is what you are doing an electron is excited from excited from level 2  $n$  is equal to 2 to higher energy levels and when it comes back and it comes back to 2, when it comes back to energy level 2 then the light in the visible region will be absorbed ~~absurd~~ light in the visible region will be absorbed ~~observed~~.

So for absorption for going from  $n$  is equal to 2 to  $n$  is equal to 3  $n$  is equal to 2 to  $n$  is equal to 4 a 2 to  $n$  is equal to 5  $n$  is equal to 2 to  $n$  is equal to 6 you will need light in the visible region light in the visible region ~~let us~~ suppose you are trying to go you are trying to make an electron of hydrogen atom in the ground state to go to higher energy levels you will have to supply energy in UV region not in visible region.

~~not in visible region~~So electrons from state  $n$  is equal to 1 cannot go I cannot go when electron is in  $n$  is equal to 1 it will not absorb visible light and when it is coming back to  $n$  is equal to 1 it will again not emit light of visible region so that is what we mean by quantization of energy.

So electron can only take certain value of energy and if you supply light which does ~~not~~ corresponds to the difference between the energies which electron can take there will be no transition there can be no transition.

(~~Reference~~Refer Slide Time 17:32)

Difference between a baseball and an electron

- Classical mechanics describes the motion of a baseball, the spinning of a top, and the flight of an airplane.
- Quantum mechanics describes the motion of electrons and the shapes of molecules such as trans fats, as well as electrical conductivity and superconductivity.

Now, there is important difference between macroscopic particle and an electron electron is a microscopic particle classical [Mechanics](#) describes the motion of baseball the spinning of a top and the flight of an airplane.

[So](#) I told you that baseball cannot behave as a wave and in that case it is classical mechanics which is going to describe the motion of a baseball but for particles like electrons particles like electrons which behave as a wave classical mechanics cannot describe its motion.

[This](#) quantum mechanics which will describe the motion of electrons and the shape of molecules such as [transfer](#) as well as electrical conductivity [in](#) and super conductivity so let us go and see how to describe motion of an electron.

[\(Refer Slide Time: 18:41\)](#)

[So](#) motion of an electron was described by [\(Schrodinger equation\)](#) Schrodinger equation he gave very important mathematical formulation to describe an electron trajectory. [an electron trajectory.](#)

([ReferenceRefer](#) Slide Time 19:21)

### Basis of Schrödinger Equation

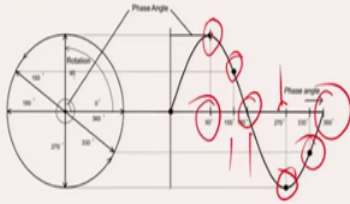

- Electrons behaves like wave.
- Momentum of electron is related to the wavelength by equation

$$\lambda = \frac{h}{p}$$

So, what is basis of his round injury question he basically was influenced by [Dee Broglie](#) he took this hypothesis that electrons behaves like a wave and momentum of electron is related to the wavelength by equation  $\lambda = \frac{h}{p}$  so since electrons behave like a wave so [a wave equation](#) our very question can equation of a wave can describe the trajectory of electron.

([ReferenceRefer](#) Slide Time 19:51)

### Equation of a standing wave

$$y(\theta) = A \sin \theta$$

<https://physics.stackexchange.com/questions/142888/wave-displacement-with-phase-difference-180>

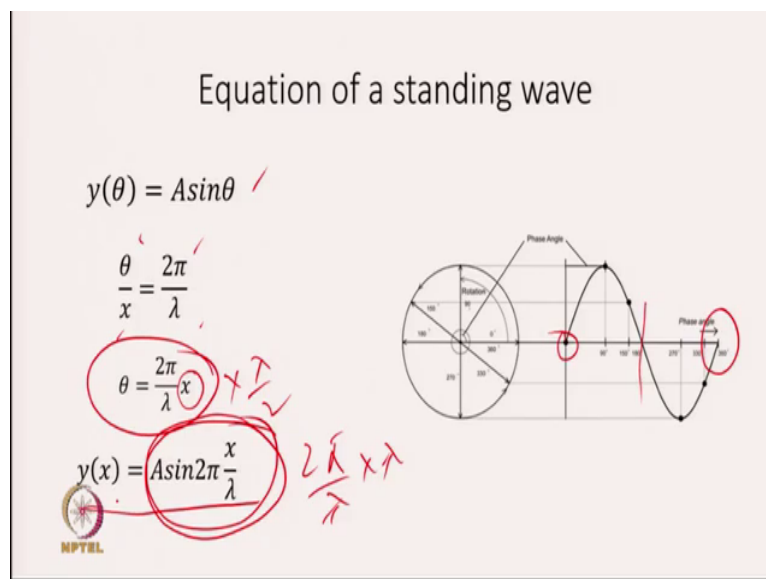

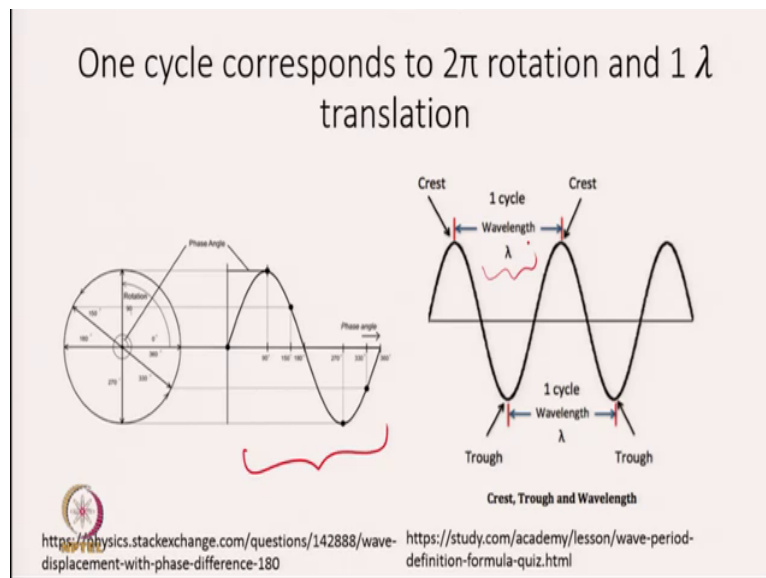

So let's think about how we can [show](#) a question of a stationary or which is not moving okay so this is your wave and I have already explained what I mean by face and this is this corresponds to zero phase this position corresponds to 90 degree phase this position corresponds to 150 degree this position corresponds to 180 degree this position corresponds

to 270 degree phase and this position corresponds to 330 degree phase and this position corresponds to 360 degree phase.

So what is the relation between  $y$  and this phase  $\theta$  is basically vertical displacement so you see when theta is 0,  $y$  is 0 when theta is 90 degree, your  $y$  is maximum, theta is 90 degree then  $y$  is maximum so this wave must be defined by the sine function.

So  $y$  is your function of this phase and that is given by a sine theta it is given by a sine theta so when theta is 0,  $y$  is 0 when theta is 90 degree,  $y$  is maximum when theta is 180 then sine 1 it is 0 so again vertical displacement is 0. So equation of a stationary wave is function of theta and it will be given by  $y \theta$  is equal to ae sine theta.

(Reference Refer Slide Time 21:27)

Now let's convert this theta or try to express the equation as a function of distance so what you will see is we know that one cycle is equal to 360 degree phase and we also know that one cycle the distance covered is lambda distance covered is lambda. So basically 360 degree phase is equal to one lambda

in them (Refer Slide Time: 22:14)

~~so basically 360 degree phase is equal to one lambda~~ so the relationship between theta and  $x$  which is your horizontal displacement theta by  $x$  is equal to  $2\pi$  by lambda theta by  $x$  is equal to  $2\pi$  divided by lambda.

So you can see that theta goes to  $2\pi$  then  $x$  will go to lambda and theta is given by  $2\pi$  by lambda into  $x$  now you can see if  $x$  is 0 theta is 0 so at this position at this point when  $x$  is equal to lambda by 2 if you put here then  $2\pi$  by lambda into lambda by 2 lambda lambda R cancels out so this will be  $\pi$  and you see 180 degree.

When  $x$  is equal to lambda then what will happen  $2\pi$  by lambda into lambda so theta is equal to  $2\pi$  ~~theta is equal to  $2\pi$~~  so the relation between theta and  $x$  is  $\theta$  by  $x$  is equal to  $2\pi$  by lambda which tells you that theta is equal to  $2\pi$  by lambda into  $x$  and when you put in this equation when you plug in this equation what you will get is  $y = A \sin \frac{2\pi}{\lambda} x$  is equal to a sine  $2\pi \frac{x}{\lambda}$  a sine  $2\pi \frac{x}{\lambda}$  by lambda now here you see this equation is this term is function of  $x$  and so now we are writing  $y$  as a function of  $x$   ~~$y$~~  as a function of  $x$ .

(Reference Slide Time 24:02)

Equation of a wave

- If wave travels in positive x-direction with velocity v

Distance travelled by the wave in time  $t = vt$

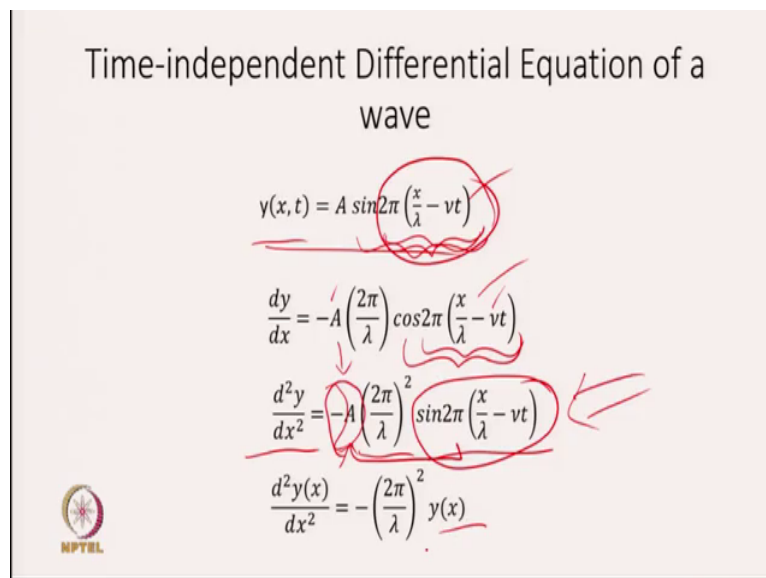

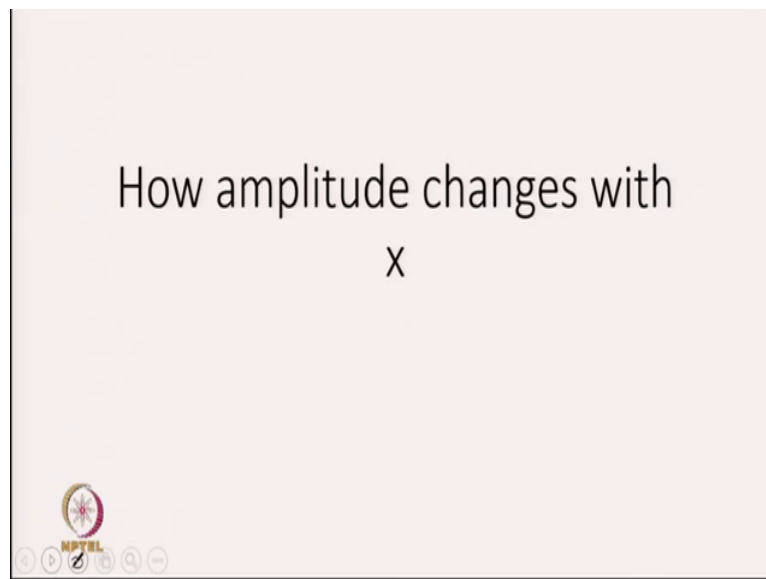

$$y(x, t) = A \sin 2\pi \left( \frac{x}{\lambda} - \frac{vt}{\lambda} \right) \quad y(x, t) = A \sin 2\pi \left( \frac{x}{\lambda} - vt \right)$$

So first we described how to write  $y$  as a function of  $\theta$  now we described how to write  $y$  as a function of  $x$  till now we have looked at what will be the equation of wave which is standing or which is just stationary wave but suppose if wave travels in positive x direction with velocity  $v$  then what you expect that distance travelled by the wave and the  $x$  direction will be  $v$  into  $t$ .

In that case your  $y$  which is vertical displacement will be given by a sine  $2\pi$   $X$  by  $\lambda$  minus  $v t$  by  $\lambda$   $X$  by  $\lambda$  minus  $vt$  by  $\lambda$  now you see this  $vt$  velocity into time is your distance.

So basically this is  $x$  by  $\lambda$  minus another distance  $v t$  by  $\lambda$  so now  $y$  is a function of  $x$  and  $t$   $y$  is a function of  $x$  and  $t$  and  $v$  by  $\lambda$  is equal to frequency  $v$  by  $\lambda$  is equal to frequency so  $y$  as a function of  $x$  and  $t$  will be given by a sine  $2\pi$   $x$  by  $\lambda$  minus frequency multiplied by  $t$  so both are  $x$  by  $\lambda$  is unit less and frequency into time is unit less now we want to know how this vertical displacement which is  $y$  changes with  $x$ .

(Reference Slide Time 25:43)

So how this amplitude changes with  $x$  so this is the same equation taken from earlier slide if I differentiate  $y$  with respect to  $x$  what I am going to get is a multiplied by we know that differential of sine  $x$  with respect to  $x$  will be minus cos x all right and here it is sine  $2\pi \frac{x}{\lambda} - vt$  by lambda minus nu  $T$  so what I am going to get is minus  $A$  into cos  $2\pi \frac{x}{\lambda} - vt$  by lambda  $\frac{2\pi}{\lambda}$  frequency multiplied by time and then we need to differentiate this term which is with sign and that will be equal to  $2\pi$  by lambda since  $T$  is constant  $C$ .

since T is constant Here we are assuming that it is that time is constant in that case this will not change when we differentiate with respect to  $x$  so minus a  $2\pi$  by lambda so differential of this  $2\pi \frac{x}{\lambda} - vt$  by lambda minus nu into  $T$  will be equal to  $2\pi$  by lambda  $2\pi$  by lambda okay.

If I differentiate again with respect to  $x$  what I am going to get is minus  $a$  as like this for  $\cos$  I will get sine ~~term~~ so sine term now again we have to differentiate this function  $2\pi x/\lambda$  by  $\lambda$  minus frequency into  $T$  and then what I am going to get is  $2\pi$  by  $\lambda$  again and so this will be  $2\pi$  by  $\lambda$  square and if you look at this wave function what you will find out is that this has minus  $A$  term and this has this term which basically combined is equal to  $y(x,t) = A \sin(2\pi(x/\lambda - vt))$  and you can simply write here by  $x$  in place of this multiplied by  $2\pi$  by  $\lambda$  square with minus sign.

~~with~~ and so minus does not come in here so minus sign ~~so~~  $d^2 y(x,t) / dx^2$  is equal to minus  $2\pi$  by  $\lambda$  square  $y(x,t) = A \sin(2\pi(x/\lambda - vt))$  so this is time independent differential equation of a wave since we have taken  $t$  as a constant  $t$  as a constants so this is applied to any kind of wave this equation is applied to any kind of wave that means it is applied to water waves it will we applied to a sound wave and also it is applied to light wave now till this point we were not considering about we are just considering the motion of a wave.

(Reference Slide Time 29:05)

### Differential Equation of a wave associated with electron

- The de Broglie wave for a particle is made up of a superposition of an infinitely large number of waves of the form

$$\psi(x,t) = A \sin 2\pi \left( \frac{x}{\lambda} - vt \right)$$

$$\frac{d^2 \psi(x)}{dx^2} = - \left( \frac{2\pi}{\lambda} \right)^2 \psi(x)$$

Now, let us come to see how we can write a differential equation of a wave associated with electron associated with electron so here the proposition made by ~~Dede~~ Broglie comes into picture what he told that ~~Dde~~ Broglie wave for a particle is made up of a superposition of infinitely large number of waves of this form and for this kind of wave you have this differential equation now only thing what we have done is in place of  $y$  we are now writing  $\psi(x,t)$  where  $\psi$  of a function the  $\psi$  of wave function okay so this is your wave function associated with electron.

(Reference Slide Time 29:59)

$$\frac{d^2\psi(x)}{dx^2} = -\left(\frac{2\pi}{\lambda}\right)^2 \psi(x)$$
$$\left(\frac{\partial^2}{\partial x^2} + \frac{\partial^2}{\partial y^2} + \frac{\partial^2}{\partial z^2}\right) \psi(x, y, z) = -\left(\frac{2\pi}{\lambda}\right)^2 \psi(x, y, z)$$
$$\nabla^2 \psi(x, y, z) = -\left(\frac{2\pi}{\lambda}\right)^2 \psi(x, y, z)$$

The combination of second partial derivatives is called Laplacian

NPTEL

Now, what next so at this point what we are talking is one dimensional movement of the wave so this is your the equation for an electron when the wave associated with electron is moving in  $x$  direction but suppose if wave is moving in three dimensional space ~~three dimensional space~~ then this equation can be written like this.

So now differential the double differential or second differential will be not only with respect to  $x$  but it will also be with respect to  $y$  and with respect to  $z$  so your light del square by del  $x$  square plus del square by del  $y$  square plus del square by del  $z$  square in place of d square by  $x$  square and now size is your function of  $x, y, z$ .

So same equation just only written in three dimension and to make things sort you replace this sum of three second order derivative by del square and this combination of second partial derivative is known as Laplacian so this only simplifies the thing so now this is your equation of a wave associated with electron in three dimension.

(Reference Slide Time 31:51)

For a particle with Energy E in a region of potential energy V

$$\nabla^2 \psi(x, y, z) = - \left( \frac{2\pi}{\lambda} \right)^2 \psi(x, y, z)$$

$$\lambda = \frac{h}{[2m(E - V)]^{1/2}}$$

$$\left( \frac{2\pi}{\lambda} \right)^2 = \frac{4\pi^2 \times 2m \times (E - V)}{h^2} = \frac{8\pi^2 m(E - V)}{h^2}$$

$$E = \frac{1}{2}mv^2 + V = \frac{p^2}{2m} + V$$

$$p = [2m(E - V)]^{1/2} \quad p = (E - V) \cdot 2m$$

$$\lambda = \frac{h}{p} = \frac{h}{[2m(E - V)]^{1/2}}$$

Now, what Schrodinger did is he replaced this lambda by  $\frac{h}{p}$  so he was influenced by the hypothesis of De Broglie we're deep Broglie predicted that lambda is equal to  $\frac{h}{p}$  so lambda associated with an electron is  $\frac{h}{p}$ .

So what can be done is just replace this lambda by  $\frac{h}{p}$  so let us think so for a particle energy will be given by kinetic energy plus potential energy which is half  $m v^2$  square plus  $V$  is your potential energy and we know that the kinetic energy is also equal to  $\frac{p^2}{2m}$  square by 2\_m from that you can calculate what will be the value of  $p$   $p$  will be simply  $e$   $p$  square will be you  $e$   $p$  square will be  $e$  minus  $V$  into 2 m and so  $p$  is equal to  $2 m e$  minus  $V$  a square root and we know that from De Broglie equation lambda of an electron will be given by  $\frac{h}{p}$ .

So lambda can be replaced by  $\frac{h}{p}$  the square root of this so when you replace this lambda by this expression what you'll get is  $2 \pi e$  by lambda square will be  $8 \pi e$  a square m e minus  $V$  by  $h$  square so Schrodinger took your equation of wave and then he plugged in value of lambda.

(ReferenceRefer Slide Time 33:-48)

$$-\left(\frac{\hbar^2}{8\pi^2m}\right)\nabla^2\psi(x,y,z) + V(x,y,z)\psi(x,y,z) = E\psi(x,y,z)$$
$$-\left(\frac{\hbar^2}{8\pi^2m}\right)\left(\frac{\partial^2}{\partial x^2} + \frac{\partial^2}{\partial y^2} + \frac{\partial^2}{\partial z^2}\right)\psi(x,y,z) + V(x,y,z)\psi(x,y,z) = E\psi(x,y,z)$$

He plugged in value of lambda from [Dee broglieBroglie](#) equation and what he got is well-known Schrodinger equation well-known Schrodinger equation and that is your minus  $\hbar^2$  square by 8 pie square m the [\(34:02\)eeH-depletion](#) operator into wave function plus potential energy into wave function will give you energy into wave function and this is well known [Schrodinger throughout dinger](#) equation. So Schrodinger utilized the concept given by de Broglie to derive equation this can tell you about trajectory of electron.

(ReferenceRefer Slide Time 33:-48)

Schrödinger Equation

- Energies of different energy levels can be obtained by solving wave equation also known as “**Schrödinger equation**”.

$$-\left(\frac{\hbar^2}{8\pi^2m}\right)\frac{d^2\psi(x)}{dx^2} + V\psi(x) = E\psi(x)$$
$$\hat{H}\psi(x) = E\psi(x)$$

The solution of this equation can give wavefunctions and energy associated with different levels.

Good thing about this equation is if you solve this equation you can get the wave function and energy associated with the different quantized level. ~~energy associated with different quantized energy level~~ This is your Schrodinger equation and this whole term so this is your kinetic energy term this is a potential energy term and that is given by operator  $\hat{H}$ .

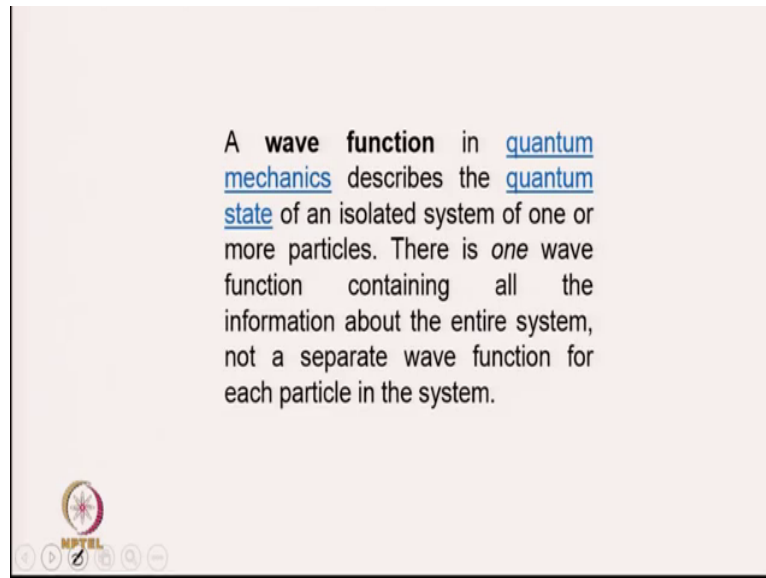

$\hat{H}\psi$  will just talk about operator  $\hat{H}$  or operators what are operators but this is your equation which is known as SI is equal to  $E$  side in this equation what you are doing is you are applying Hamiltonian operator which is given by this symbol and getting your energy value getting the energy value. so when you apply the Hamiltonian operator on the wave function what you are going to get is energy multiplied by the wave function energy multiplied by the wave function.

(Reference Refer Slide Time 36:06)

Now, there are two very important thing which comes into this ~~Schrodinger~~ equation one is wave function and another is operator in this case Hamiltonian operator so now let us discuss what are these parameters so wave function quantum mechanics acknowledges the wave particle duality of matter by supposing that rather than traveling along a definite path a particle is distributed through space like ~~wave away~~ and the wave that in quantum mechanics replaces the classical concept of particle trajectory is known as wave function so basically wave function describes the trajectory of your microscopic particles.

(ReferenceRefer Slide Time 37:00)

So, a wave function in quantum mechanics describes the quantum state of an isolated system of one or more particles there is one wave function containing all the information about the entire system not a separate wave function for each particle in the system that is very important part just by knowing the wave function you can tell all the information about the system all the information about the system.

-So what is momentum what is position what is your kinetic energy what is total energy this things the information about this parameter is contained in ~~is contained~~ in the wave function.

(Reference Refer Slide Time 38:02)

**Postulates of Quantum Mechanics**

**Postulate 1:**

**State and wave functions. Born interpretation**

The state of a quantum mechanical system is completely specified by a wave function  $\psi(r,t)$  that depends on the coordinates of the particles ( $r$ ) and time  $t$ . These functions are called wave functions or state functions.

For 2 particle system:

$$\Psi = \Psi(x_1, y_1, z_1, x_2, y_2, z_2, t)$$

Wave function contains all the information about a system.

wave function	↔	classical trajectory
(Quantum mechanics)		(Newtonian mechanics)

**Meaning of wave function:**

$$P(r) = |\psi|^2 = \int \psi^* \psi d\tau$$

=> the probability that the particle can be found at a particular point  $x$  and a particular time  $t$ . (Born's / Copenhagen interpretation)

Now, let us go and try to understand wave function a bit let us go and try to ~~this disappoint~~ of mechanics so quantum mechanics is described by different postulates different postulate what I mean by postulate is there are certain rules have been given there are certain rules have been given and you take it as a it has face value and what it has been seen is that if you accept the postulates of quantum mechanics then the information about a microscopic particle ~~information of a microscopic particle can be obtained~~ can be obtained.

So first postulate is the state of a quantum mechanical system is completely specified by a wave function which depends on the coordinates of the particle and time  $t$  so I have already talked to you that ~~sipsy isze~~ your wave function of ~~X x y z Y Z~~ and  $t$ .

So this is for one particle system for two particle system a wave function will be a function of position of the first particle position of the second particle  $n$  type so wave function will be a function of  $x_1 y_1 z_1 x_2 y_2 z_2$  and time  $T$ .

Wave function contains all the information about the system and wave function is similar to classical trajectory in Newtonian mechanics wave function tells you about trajectory in the quantum mechanics what is the physical significance, physical significance is that you can get the you can find probability of particle ~~in aena~~ or around a particular point ~~x X, particular point X~~ by using this equation.

So probability is given by your ~~side'phy~~ star into ~~sypsy~~ to ~~D tau D tau psySIA~~ star into size is known a probability density when it is multiplied by volume element and you integrate it you will get probability of finding an electron in a particular region in detail region.

S—so psysize stars I tells you about probability density and thatthere is synonymous to amplitude square amplitude square which is proportional to intensity and now you think of that what happens if volume element is small finding of an electron in a small volume element will be smaller.

S—so suppose in this room electron can be anywhere and suppose you choose youra very small space in this room okay in thenis room then probability of finding electron in this volume element will be very small and in comparison to this whole whole room this whole room and so probability is proportional to  $D \tau$   $D \tau$  is big then probability it will be B-b and that is's why  $P R$  is proportional to  $D \tau$   ~~$P R$  is proportional to  $D \tau$~~   $P R$  r is also proportional to psysize star psy€ which the probability density and I explained that by giving you or by giving an analogy to ~~(intensity dependence on amplitude)~~ intensity dependence on amplitude.

### Implications of Born's Interpretation

(1) Positivity:  
 $P(\mathbf{r}) \geq 0$

The sign of a wavefunction has no direct physical significance:  
The positive and negative regions of this wavefunction both correspond to the same probability distribution.

(2) Normalization:  
$$\int_{\text{all\_space}} \Psi^* \Psi d\tau = 1$$

i.e. the probability of finding the particle in the universe is 1.

### Physically acceptable wave function

➤ The wave function and its first derivative must be:

- 1) Finite. The wave function must be single valued. This means that for any given values of  $x$  and  $t$ ,  $\Psi(x,t)$  must have a unique value. This is a way of guaranteeing that there is only a single value for the probability of the system being in a given state.

So, there are a few things which is needed your  $P(\mathbf{r})$  must be greater than equal to zero-0 here sine of wave function has no direct physical significance the positive and negative region of this wave function both correspond to same probability distribution the second thing is that that if you integrate  $\Psi^* \Psi d\tau$  over all space it should be equal to 1 and that is not a very difficult thing to understand because probability of being an electron from minus infinity to plus infinity is going to be one going to be 1. Since probability of finding the particle in the inverse is 1 and that is what size should follow

(Refer Slide Time: 43:33)

## Physically acceptable wave function

- The wave function and its first derivative must be:
  - 1) Finite. The wave function must be single valued. This means that for any given values of  $x$  and  $t$ ,  $\Psi(x,t)$  must have a unique value. This is a way of guaranteeing that there is only a single value for the probability of the system being in a given state.

So there are certain rules for a acceptable wave function and that is based on the real things wave function and its first derivative must be finite or the wave function must be single valued what does that mean it means for any given value of  $x$  and  $t$  ~~psysigh~~ a wave function must have unique value and why this condition because this is way of guaranteeing that there is only a single value of probability of the system ~~(being in a given estate)~~ being in a given estate and that is quite ~~h~~logical.

(~~RefereneeRefer~~ Slide Time 44:22)

## 2. Square-integrable

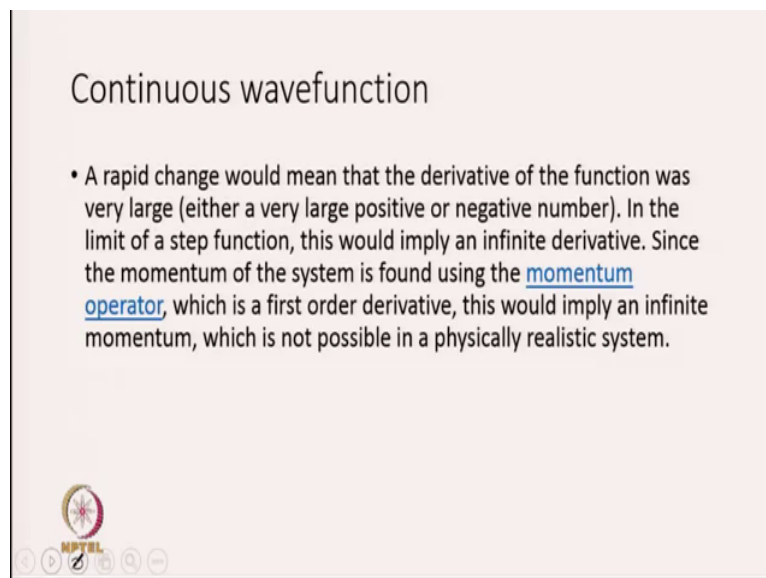

The wave function must be square-integrable. In other words, the integral of  $|\Psi|^2$  over all space must be finite. This is another way of saying that it must be possible to use  $|\Psi|^2$  as a probability density, since any probability density must integrate over all space to give a value of 1, which is clearly not possible if the integral of  $|\Psi|^2$  is infinite. One consequence of this proposal is that  $\Psi$  must tend to 0 for infinite distances.

The second thing is wave function must be square integrable so what does that mean is the integral of ~~psysy~~ square over all space ~~must be finite~~ must be finite what we are telling by this is it is also logically valid because what we are trying to say by saying that function must be a square integrable is that the probability density must integrate over all space to give a value

of 1 and which is not possible if the integral of  $\psi^2$  is infinite and this also gives you one very important consequence that  $\psi$  must tend to zero for infinite distance in finite distance.

(Reference Slide Time 45:28)

Continuous wavefunction

- A rapid change would mean that the derivative of the function was very large (either a very large positive or negative number). In the limit of a step function, this would imply an infinite derivative. Since the momentum of the system is found using the [momentum operator](#), which is a first order derivative, this would imply an infinite momentum, which is not possible in a physically realistic system.

NPTEL

The next criteria for acceptable wave function is that wave function must be continuous a rapid change would mean that the derivative of function was very large is very large in the limit of a step function this would imply an infinite derivative later we will find out that momentum of system is calculated using momentum operator which is first order derivative and if there is a rapid change it means the derivative of the function will be very large. It means in finite momentum which is not possible in a physically realistic system. ~~which is not possible in a physically realistic system.~~

([ReferenceRefer](#) Slide Time 46:21)

### Continuous First derivative

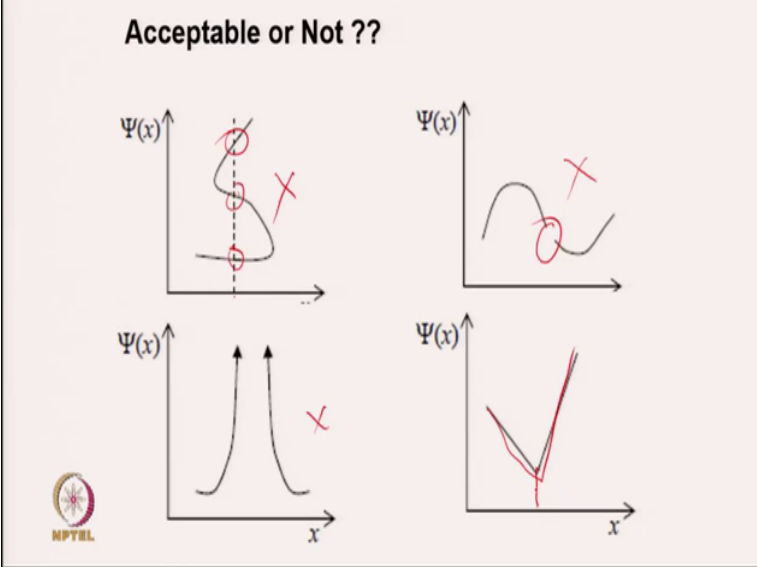

1. All first-order derivatives of the wave function must be continuous. Following the same reasoning as in condition 3, a discontinuous first derivative would imply an infinite second derivative, and since the [energy](#) of the system is found using the second derivative, a discontinuous first derivative would imply an infinite energy, which again is not physically realistic.

So, all first order derivative of the wave function must be continuous following the same reasoning as we did in the last [last](#) criteria a discontinuous first derivative would imply an infinite second derivative and generally energy of the system is calculated using second derivative so discontinuous first derivative will mean an infinite energy again which is not physically realistic.

### Acceptable or Not ??

The figure shows four graphs of wave functions  $\Psi(x)$  versus  $x$ . Each graph is marked with a red 'X' to indicate it is not acceptable. The first graph shows a wave function with a vertical jump discontinuity at  $x=0$ . The second graph shows a wave function with a sharp cusp at  $x=0$ . The third graph shows a wave function with a vertical asymptote at  $x=0$ . The fourth graph shows a wave function with a sharp cusp at  $x=0$ .

So, if you look at these wave functions this wave function is not acceptable since at this finite value of  $x$  you will have three different values of  $y$  of size  $x$  so it is the wave function is not a single valued function now the second one is also not accepted because it is a discontinuous wave function third again is not acceptable and fourth is also not acceptable

because you see there is a very sharp change in the wave function at this particular position of  $X$  so these wave functions are not acceptable.

(Reference Slide Time 47:45)

Acceptable or not acceptable ??

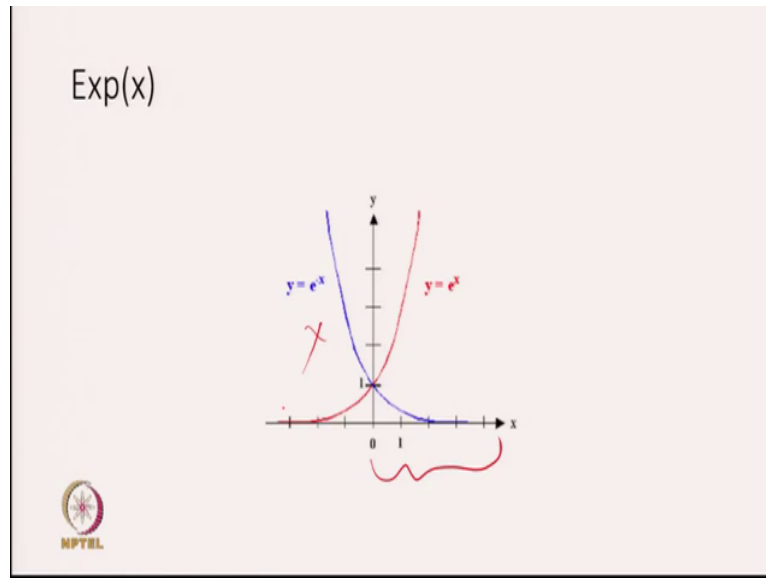

- (i)  $e^{-x}$  ( $0, \infty$ )
- (ii)  $e^{-x}$  ( $-\infty, \infty$ )
- (iii)  $\frac{\sin x}{x}$
- (iv)  $\sin^{-1} x$

The slide contains a list of four functions with a red curly bracket on the right side grouping them. The functions are: (i)  $e^{-x}$  ( $0, \infty$ ), (ii)  $e^{-x}$  ( $-\infty, \infty$ ), (iii)  $\frac{\sin x}{x}$ , and (iv)  $\sin^{-1} x$ . In the bottom left corner, there is a circular logo with a star and the text 'NPTEL' below it.

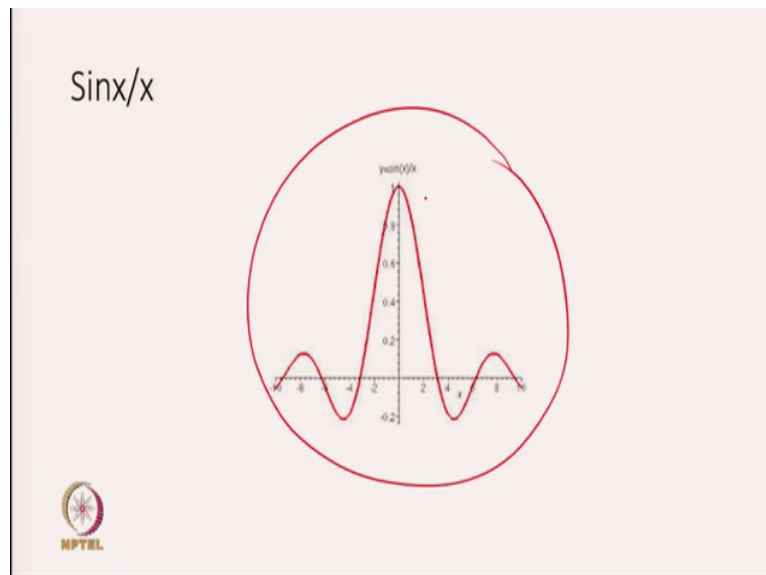

Now, let us think about these four different kinds of functions: exponential minus  $x$  from  $0$  to infinity, exponential minus  $x$  from minus infinity to infinity, sine  $x$  by  $x$ , and sine inverse  $x$ .

(ReferenceRefer Slide Time 48:00)

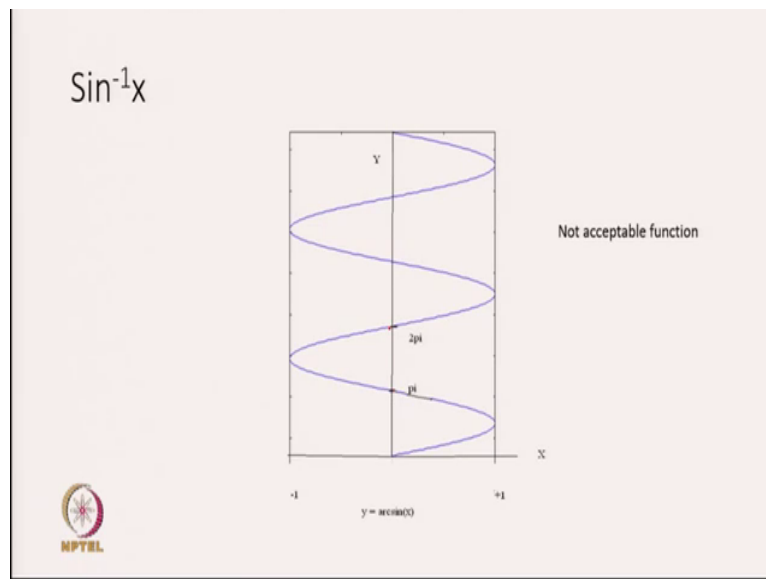

So in exponential  $\frac{e^{-x}}{e^x}$  this is exponential minus  $\frac{e^x}{e^{-x}}$  so you can see the plot between  $\frac{e^{-x}}{e^x}$  exponential minus  $\frac{e^x}{e^{-x}}$  as a function of  $\frac{e^{-x}}{e^x}$  now you see here this wave function is acceptable if we take from 0 to infinity if we remain in the region 0 to infinity but this is not acceptable in a reason when you go from  $\frac{e^{-x}}{e^x}$  (0 to minus infinity) 0 to minus infinity.

(ReferenceRefer Slide Time 48:44)

Sine  $\frac{\sin(x)}{x}$  by  $\frac{\sin(x)}{x}$  this is an acceptable wave function it meets all the criteria for an acceptable wave function.

(ReferenceRefer Slide Time 48:57)

Sine inverse  $x$  this is the plot of sine inverse  $x$  versus  $x$  is a plot of sine inverse  $x$  versus  $x$  now you can see that  $x$  will be 0 at  $y$  is equal to 0  $y$  is equal to  $\pi$   $y$  is equal to  $2\pi$  and so on so this wave function is not a single valued function and so it ~~cannot be a acceptable wave function~~ cannot be acceptable wave function.

(ReferenceRefer Slide Time 49:31)

**Postulate 2**

To every physical property, observable in classical mechanics, there corresponds a linear, hermitian operator in quantum mechanics.

The slide contains the text "Postulate 2" in red, followed by the statement: "To every physical property, observable in classical mechanics, there corresponds a linear, hermitian operator in quantum mechanics." The NPTEL logo and navigation icons are at the bottom.

Now, a postulate 2 tells you for every physical property observables in classical mechanics there corresponds a linear hermitian operator in quantum mechanics so there are three important part of this postulate money observable what we mean by observable and then the

second is operator third is your linear and fourth is hermitian so we will go to every this four of them one by one and try to understand what we mean by this.

([ReferenceRefer](#) Slide Time 50:-31)

### Observables

- Anything which is function of position or/and momentum

Position:  $x$  ✓  
Momentum:  $p_x$  ✓  
K.E.:  $\frac{p_x^2}{2m}$  ✓  
P.E.:  $V(x)$  ✓  
T.E.:  $\frac{p_x^2}{2m} + V(x)$  ✓

So, let's discuss about your observables what are observables, observables are anything which is a function of position or and momentum for example position is a function of X momentum which is function of p x kinetic energy which is a function of P momentum your potential energy which is a function of position and total energy which is a function of position and momentum so these are the observables.

([ReferenceRefer](#) Slide Time 51:-07)

### Operator

- A rule that transforms a given function into another function

$$\hat{O}f(x) = g(x)$$

What are operators? operator is a rule that transforms a given function into another function so if you apply operator  $\hat{O}$  on a function  $f(x)$  it will give you another function which is your  $g(x)$  so operator transforms a given function into another function so here operator  $\hat{O}$  is converting a function  $f(x)$  into another function  $g(x)$ .

(Reference Slide Time 51:50)

Operator

- Example. Apply the following operators on the given functions:
- (a) Operator  $d/dx$  and function  $x^2$ .
- (b) Operator  $d^2/dx^2$  and function  $4x^2$ .
- (c) Operator  $(\partial/\partial y)x$  and function  $xy^2$ .
- (d) Operator  $-i\hbar d/dx$  and function  $\exp(-ikx)$ .
- (e) Operator  $-\hbar^2 d^2/dx^2$  and function  $\exp(-ikx)$ .

Handwritten calculations:

$$\frac{d}{dx}(x^2) = 2x$$

$$\frac{d^2}{dx^2}(4x^2) = \frac{d}{dx}(8x) = 8$$

Now, let us understand by some examples so suppose either operator  $\hat{D}$  by  $d/dx$  when I apply that on function  $x^2$  square we will get another function  $2x$   $\hat{D}$  by  $d/dx$  is  $x^2$  square  $\hat{D}$  by  $d/dx$   $x^2$  square is equal to  $2x$ .

So this is first function when you apply this operator  $\hat{D}$  by  $d/dx$  it will give another function which is equal to  $2x$  similarly when we apply operator  $d^2/dx^2$  square on  $4x^2$  square what we will get will get first  $\hat{D}$  by  $d/dx$   $8x$  and then this will give you  $8$  this will give you  $8$ .

So when we apply this operator ~~this operator~~ double differential operator on the function  $4x^2$  square we are going to get  $8$  similar kind of operator you can see here and you can practice what you will get when you apply these operators on these functions on these functions this is about operator part.

(Reference Refer Slide Time 51:50)

Linear Operator

- A linear operator has the following properties

$$\hat{A}(f_1 + f_2) = \hat{A}f_1 + \hat{A}f_2$$
$$\hat{A}(cf) = c\hat{A}f$$

*PS here root operator*

$\sqrt{f_1 + f_2} \neq \sqrt{f_1} + \sqrt{f_2}$

What is a linear operator a linear operator has the following property if I take a combination of two function  $f_1$  and  $f_2$  and if I apply a linear operator you take that value and then what you do that apply this linear operator to function  $f_1$  and  $f_2$  separately then the two values must be equal to values must be equal.

Now you will see that it should be equal for every operator no it is not like that for example suppose you have a square root operator ~~a square root operator operator~~ okay so a square-root operator for example this one  $f_1 + f_2$ ,  $f_2$  will not be equal to a square root of  $f_1$  plus a square root of  $f_2$  s square root of Hecto.

So-so this condition does not hold true for every operator but this will be true for a differential operator this will be true for a differential operator so differential operator is a linear operator so when operator is applied to a combination of two different function and it is equal to then apply some of your when you apply operators separately to this two function then you have a linear operator.

The second condition which also should be maintained is when you apply this operator to a function multiplied by a constant you must get constant multiplied by ~~operator of that function constant x operator~~ of that function so two condition you apply operator to the combination of two wave functions if it is equal to operator of function  $f_1$  plus then plus operator of function  $f_2$  and the second is an operator is applied to a constant multiplied wave function that should be equal to constant multiplied by operator of this function. so we

discussed observables we discussed your operator I ~~discussed first~~ your linear operator so now we will go to hermitian operator.

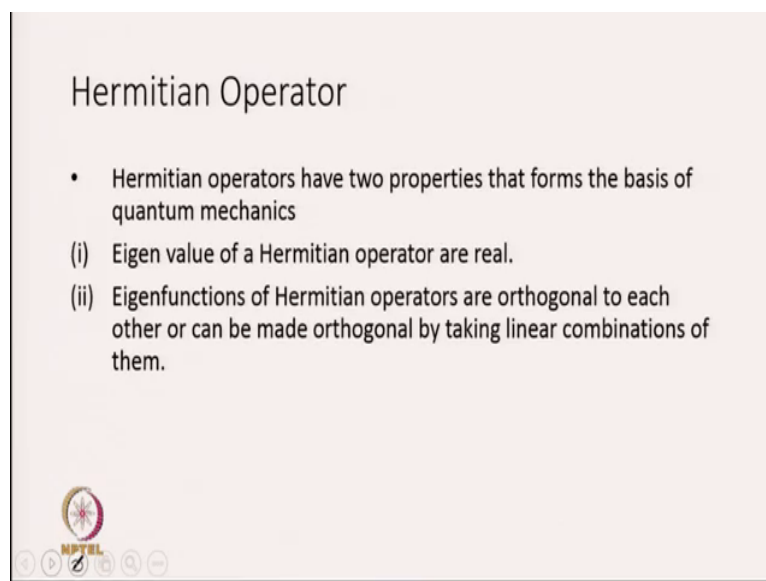

([Reference](#) Slide Time 56:4-5050)

Linear operator

- Derivative
- integrals
- log
- √

 NPTEL

Hermitian Operator

- Hermitian operators have two properties that forms the basis of quantum mechanics
  - (i) Eigen value of a Hermitian operator are real.
  - (ii) Eigenfunctions of Hermitian operators are orthogonal to each other or can be made orthogonal by taking linear combinations of them.

 NPTEL

But before that I will tell you to look at these four questions to look at these operators and tell whether these operators are linear or not so check whether derivative is a linear operator where integral is a linear operator the log is a linear operator where a square root is a linear operator I just discussed about a square root it is not a linear operator.
