Homogeneous 2nd order ODEs, solution using basis functions

(Refer Slide Time: 00:19)

Module 6: Second Order ODEs
Homogeneous/Nonhomogeneous
equations

- Types of 2nd order ODEs, nature of solutions
- Homogeneous 2nd order ODEs, solution using basis functions
- Homogeneous and nonhomogeneous equations
- Nonhomogeneous equations – Variation of parameters
- Practice Problems.

So we talked about the different types of second order differential equations in the last class and we talked about what kind of solutions you can have. Now in this class I will be focusing on homogenous second order ODEs and writing solutions in terms of basis functions. We already saw a bit of this in the last class and what I will do today is actually formalize some of the things that you saw in the last class.

(Refer Slide Time: 00:43)

Homogeneous Second order
Differential Equations

NPTEL

$$y'' + A(x)y' + B(x)y = 0$$
$$y' = \frac{dy}{dx} \quad \text{and} \quad y'' = \frac{d^2y}{dx^2}$$

If $y_1(x)$ is a solution of DE

$$\Rightarrow y_1'' + A y_1' + B y_1 = 0$$

$C y_1(x)$ is also a solution

So, let us get back to our homogeneous second order differential equation. So, I will write it in the following form I will write y double prime plus A of x y prime plus B of x y equal to 0. So, this is our homogeneous second order differential equation and what you can see is that suppose you have this differential equation and let me remind you that y prime equal to $d y$ by $d x$ and y double prime equal to d square y by $d x$ square. So, suppose you have a differential equation like this and let us say if y_1 of x is a solution of differential equation. So, if y_1 of x is a solution of this differential equation; that means, this implies that y_1 double prime plus $A y_1$ prime plus $B y_1$ equal to 0 and I have suppressed the dependence on x , I have all these are functions of x , but I am not writing the explicit dependence on x . So, if y_1 is a solution then it must satisfy this that is why it is a solution then you can see that a constant times y_1 of x is also a solution; that means, that means I can multiply y_1 by a constant and I will get another solution which is also a valid solution and you can see this because. So, suppose I had $c y_1$.

(Refer Slide Time: 02:48)

The slide, titled "Properties of Solutions", features the NPTEL logo on the left and the Indian Institute of Technology Kharagpur logo on the right. The main content is handwritten in red ink and includes the following text and equations:

$$(cy_1)' = cy_1' \quad (cy_1)'' = cy_1''$$

clearly $cy_1'' + A(x) \cdot cy_1' + B(x)cy_1 = 0$
or cy_1 is a solution of DE.

(Refer Slide Time: 04:09)

This slide continues the "Properties of Solutions" topic. It includes the same NPTEL and IIT Kharagpur logos. The handwritten text in red ink shows the derivation of the superposition principle:

$$(cy_1)' = cy_1' \quad (cy_1)'' = cy_1''$$

clearly $cy_1'' + A(x) \cdot cy_1' + B(x)cy_1 = 0$
or cy_1 is a solution of DE

Suppose y_1 & y_2 are solutions
i.e. $y_1'' + Ay_1' + By_1 = 0$ $y_2'' + Ay_2' + By_2 = 0$
 $(y_1 + y_2)'' + A(y_1 + y_2)' + B(y_1 + y_2) = 0$
 $y_1 + y_2$ is also a solution.

Now, $c y_1$ the whole thing prime the derivative of this is nothing, but c times the y_1 prime and you have $c y_1$ double prime is nothing, but c times y_1 double prime.

So, now if I take this differential equation and instead of y_1 , I place it by c times y_1 then where I have y_1 double prime, I will have c times y_1 double prime where I have y_1 prime I will have c times y_1 prime and where I have y_1 , I will have c times y_1 . So, if I make this substitution then clearly c times y_1 double prime plus A of x into c times y_1 prime plus B of x into c times y_1 equal to 0 or $c y_1$ is a solution of differential equation.

So, what; that means, is that if y_1 is a solution then any constant multiplied by y_1 is also a solution so; that means, you can have many solutions with different constants.

Now, next suppose y_1 and y_2 are solutions that if that is. So, if both these are solutions; that means, you will have $y_1'' + Ay_1 + By_1 = 0$ and if y_2 is a solution. So, you have $y_2'' + Ay_2 + By_2 = 0$. So, you have both these conditions.

Now, you can see that if I just add them then I will get $y_1 + y_2$ double prime plus A times $y_1 + y_2$ prime plus B times $y_1 + y_2$ equal to 0 or in other words $y_1 + y_2$ is also a solution. So, basically if you have 2 functions y_1 and y_2 which are solutions of the differential equations of this homogeneous differential equation you add them up you will get another solution and we already saw that you will multiply any of them by a constant you get another solution. So, this leads us to the important idea that that my solution.

(Refer Slide Time: 05:51)

Solution as a linear combination

$C_1 y_1 + C_2 y_2$
is also a solution of DE (provided y_1, y_2 are solutions)

General solution
 $y(x) = C_1 y_1(x) + C_2 y_2(x)$
 2 arbitrary constants

Q: Is this valid for any $y_1(x)$ & $y_2(x)$ that solve DE?

If I take $c_1 y_1$ plus $c_2 y_2$ is this will also be a solution of DE that is provided y_1, y_2 are solutions. So, what; that means, is that if I have one solution y_1 if I have another solution y_2 then I can write a third solution which is a linear combination of these 2 and in fact, in fact you can say that the general solution y of x can be written as a linear combination of y_1 of x plus $c_2 y_2$ of x . So, you can write a general solution as a linear combination of as these 2 solutions. So, if you have 2 solutions you can write a general

solution as the linear combination and this you notice has 2 arbitrary constants. So, we already learnt that if we have a second order differential equation the general solution will have 2 arbitrary constants. So, if you know 2 solutions y_1 and y_2 you can write a general solution and what I mean by these 2 solutions do not have any arbitrary constants. So, if y_1 and y_2 do not have any arbitrary constants then I can write a general solution as a linear combination of these and I will have my 2 arbitrary constants.

So, the question is this valid for any y_1 of x and y_2 of x that solve DE. So, that means, can you use any 2 solutions and write the general solution as a linear combination of those 2 solutions and the answer is no. So, you can take any 2 solutions you can take a linear combination you will get a solution, but in order for this solution to be a general solution in order to get a general solution the important thing is that y_1 and y_2 should be linearly independent.

(Refer Slide Time: 08:31)

Basis functions

In order for $y = c_1 y_1 + c_2 y_2$ to be a general solution of DE, $y_1(x)$ & $y_2(x)$ should be linearly independent. i.e. $y_2(x) \neq \alpha y_1(x)$

Many possible solutions \rightarrow Vector space of solutions
 $y_1(x)$ & $y_2(x)$ are basis for this vector space

$y'' + Ay' + By = 0$
ONLY for Homogeneous D.E.s

So, in order for y equal to $c_1 y_1$ plus $c_2 y_2$ to be a general solution of DE and when I say a general solution of DE I what I what I imagine is that any other solution of the DE can be written by choosing c_1 and c_2 . So, you can write any other solution by choosing c_1 and c_2 appropriately. So, in order for this to be a general solution of the of the differential equation y_1 of x and y_2 of x should be linearly independent or in other words y_2 of x is not equal to some constant α times y_1 of x . So, y_2 should not be

proportional. So, these 2 are functions and 2 functions are linearly independent if you cannot write 1 as a multiple of the other then you say that they are linearly independent.

So, now these 2 solutions, what we have right here is you have many possible solutions. So, you can think of a; this as a vector space of solutions and why are you; why are we using the vector space because you can take you can add solutions you can multiply them by a constant and you will still get a solution. So, the set of solutions will form a vector space and y_1 of x and y_2 of x e k can be a basis for this solution basis for this vector space. So, if they are linearly independent if y_1 and y_2 are linearly independent then they can be a basis for this space of solutions.

So, this is a vector space of solutions of the differential equation. So, it is a vector space of functions which solve the differential equation and this vector space of functions will have a basis of 2 functions which are also solutions of the differential equation, but which are linearly independent. So, just to show you again we had the differential equation y double prime plus A times y prime plus B times y equal to 0 and this is a homogeneous linear second order differential equation and I said A and B are functions of x . So, they can be any functions it is still a homogeneous linear second order differential equation and this has a feature that if you know 2 if you have 2 linearly independent solutions y_1 of x and y_2 of x then you can write A_j , you can write any solution as a linear combination of those 2 solutions.

So, this is extremely nice because you see a connection between the; what we were talking in terms of basis vectors for a vector space and solutions of a differential equation and remember this is only valid for this is only for homogeneous equations. So, you can only do this if the equation is homogeneous if the equation is not homogeneous you cannot suppose I suppose y_1 is a solution there is no guarantee that $c y_1$ will be a solution. So, this is not true for any equation. So, for any arbitrary equation you cannot you would not have that $c y_1$ is also a solution if y_1 is the solution this is only for homogeneous differential equation.

So, now let us illustrate another interesting idea for homogeneous equations. So, sometimes we may find we may find one solution. So, you have a differential equation.

(Refer Slide Time: 13:34)

From one solution to the other

Sometimes, we may find one solution

$$y'' + Ay' + By = 0$$

y_1 is a solution ; Can we find y_2 which is a linearly independent solution

Try $y_2(x) = u(x)y_1(x)$

$$y_2' = uy_1' + u'y_1$$

$$y_2'' = uy_1'' + u'y_1' + u'y_1' + u''y_1 = uy_1'' + 2u'y_1' + u''y_1$$

$$uy_1'' + 2u'y_1' + u''y_1 + \underline{Auy_1'} + \underline{Au'y_1} + \underline{Buy_1} = 0$$

$$u(y_1'' + Ay_1' + By_1) = 0$$

Let me let me just write the differential equation. So, you may find one solution. So, our differential equation is y double prime plus $A y$ prime plus $B y$ equal to 0 and y_1 is a solution. Now the question is can we find y_2 which is a linearly independent solution. So, we want to find another solution you want to find. So, you have one solution you want to find the second linearly independent solution. So, that you can write any solution a general solution as a linear combination of these 2 solutions and the answer is yes, you can find it, the method that you do is called variation of parameters. So, what you say is. So, you try y_2 is equal to u which is a function of x times y_1 . So, remember all these are functions of x . So, y_2 is a function of x u is a function of x and y_1 is also a function of x .

So, sometime I will not write the explicit dependent on x , but here I want to emphasize that u is a function of x just as y_1 and y_2 are also functions of x . So, suppose you try a solution of this form. So, then what is y_2 prime is $u y_1$ prime plus u prime y_1 y_2 double prime. So, that is the second derivative of y_2 now again. So, that is the derivative of this of this quantity of the first derivative. So, so if you take the derivative of the first term you will get $u y_1$ double prime plus u prime y_1 prime and then if you take the derivative of this second term you will get plus u prime y_1 prime plus u double prime y_1 . So, you have these four terms and you can see that these 2 terms are identical. So, so I can write this as $u y_1$ prime double prime plus $2 u$ prime y_1 prime plus u double prime y_1 . So, all I did was I had y equal to u time y_2 is u times y_1 then y_2 prime I

write by the usual product rule and y_2 double prime also I right by the usual product rule and now I substitute in the differential equation because y_2 has to be a solution of this differential equation.

So, when you substitute in the differential equation what do you get? So, for y_2 double prime I will put all these terms. So, I will have $u y_1$ double prime plus $2 u$ prime y_1 prime plus u double prime y_1 plus A times $u y_1$ prime plus A times u prime y_1 plus B times $u y_1$ equal to 0. So, since it has to satisfy the differential equation since we want y_2 to satisfy the differential equation we just substitute y_2 into this equation and you will get and you will come up with this equation, now you look at these terms I will just highlight them in blue. So, I look at this term then I look at this term and I look at this term. So, if I add; if I look at each of these terms as $A u$.

So, if I write the sum of these terms I have u times y_1 double prime plus A times y_1 prime plus B times y_1 and you can immediately see that the term in the brackets has to be equal to 0. So, therefore, these 3 terms will add up to 0 and if you if you set these 3 terms to 0 then you are left with only the 3 remaining terms. So, what are the 3 remaining terms?

(Refer Slide Time: 18:10)

From one solution to the other

$$2u'y_1' + u''y_1 + Au'y_1 = 0$$

$$u''y_1 = -(Ay_1 + 2y_1')u'$$

det $U = u'$ $U' = u''$

$$\frac{U'}{U} = -\frac{Ay_1 + 2y_1'}{y_1}$$

$$\ln U = -\int \left(A + \frac{2y_1'}{y_1}\right) dx$$

Can solve for $U \rightarrow u = \int U dx \rightarrow y_2 = u y_1$

So, you have $2 u$ prime y_1 prime plus u double prime y_1 and you have plus $A u$ prime y_1 equal to 0 and what I see is that there is no u term in this. So, there is no u term. So, I can just write it as u double prime y_1 is equal to minus of; now I will write it as $A y_1$

plus $2y_1'$ into u' . So, what I can do is I can bring the u'' to the left hand side and what I will get is; so I will say let capital U is equal to u' . So, I will just call it capital u and the reason will become obvious because now a capital U prime equal to u'' . So, then you will get u' I have write this as u' by u is equal to minus $A y_1 + 2 y_1'$ divided by y_1 .

Now, now you can immediately see the where we are going with this I do not want to do too much further you have a essentially separated u and x . So, remember y_1 is a function of x that you know. So, so we know we know the solution. So, y_1 is a solution that we know and from y_1 we wanted to find y_2 and what we did was we used a trial form of y_2 is u times y_1 and what we said is that when you substitute in this and then you get this relation now you can immediately write this as. So, if you integrate both sides you will get A , you will get the relation that looks like looks like the following.

So, integral of this is natural log of u is equal to minus integral $A y_1 + 2 y_1'$ by $y_1 dx$ A is a function of x remember A is a function of x . So, I just integrate it both sides with respect to x and I got this. So, I just wrote these terms explicitly, but the point is that you know y_1 . So, we can calculate y_1' and you can do this integral and you know A . So, essentially you can find out u . So, we can find out u and then u from capital U, you can find out small u and from small u you can find out y_2 . So, I will just write it. So, can solve for u and from u you go to from capital U, you go to small u which is just integral of $u dx$ and then and then from u you can go to y_2 is equal to $u y_1$.

So, what does this show? This shows that if you have one solution of the homogeneous differential equation you can go to you can get to the second solution. So, what this shows is that you know the power of homogeneous equations is that even if you just have one solution you can get to a second solution and that second solution will be linearly independent because u is not a constant u is some function of x . So, the second solution is by design it is linearly independent and the second solution being linearly independent you can write the general solution as a linear combination of y_1 and y_2 . So, what this says is that all you have to do for a second order for a second order homogeneous differential equation is to find one solution and then you can find the general solution of this second order homogeneous differential equation.

So, in the next class, I discuss second order homogeneous differential equation with constant coefficients and then I will tell what are the strategies when your second order differential equation is not homogeneous. So, I will stop here for today.
