Nonhomogeneous equations - variation of parameters

So in today's class, I am going to talk about non homogeneous second order differential equations and how you can write a general solution of a non homogeneous second order differential equation. We have already seen how to solve homogeneous differential equations or at least get solutions of homogeneous differential equations if one solution is known how you can get the second solution and so on. So, today I will talk about non homogeneous equations.

(Refer Slide Time: 00:48)

Nonhomogeneous 2nd Order ODEs

$$y'' + A(x)y' + B(x)y = C(x)$$

General Solution → 2 arbitrary constants

For corresponding homogeneous equation

$$y'' + A(x)y' + B(x)y = 0$$

General Solution is denoted as y_h (2 arbitrary constants).

So, just to remind ourselves, this non homogeneous second order differential equation looks like this $y'' + B(x)y = C(x)$ this is the general non homogeneous second order differential equation and we want the general solution. So, a general solution means we will have 2 arbitrary constants.

So, you will have 2 arbitrary constants and this is what we want to get. So, we want to get a general solution of this equation now for the homogeneous case. So, for corresponding homogeneous equation and I will just; so the corresponding homogeneous

equation is will look like $y'' + A(x)y' + B(x)y = 0$. So, for this homogenous equation the solutions have denoted as $y_h(x)$ and or simply y_h and what I should say is that this is the general solution the general solution is denoted as y_h .

So, I will use y_h as the general solution of the corresponding homogenous equation. So, y_h this will have 2 arbitrary constants we saw, how we can get y_h using linear combination of basic functions, now what we want to do is to write a general solution for this non homogeneous equation and that will also involve 2 arbitrary constants.

(Refer Slide Time: 03:12)

The slide is titled "General Solution" and features the NPTEL logo on the left and a circular institutional seal on the right. The central equation is $y(x) = y_h(x) + y_p(x)$. Handwritten annotations in red ink explain each term:

- An arrow points from $y(x)$ to the text "General Solution of Nonhomogeneous DE", with a downward arrow pointing to "2 Arbitrary constants".
- An arrow points from $y_h(x)$ to the text "General Solution of homogeneous DE", with a downward arrow pointing to "2 Arbitrary constants".
- An arrow points from $y_p(x)$ to the text "Any particular Solution of nonhomogeneous equation", with a downward arrow pointing to "No arbitrary constants".

So, I will just at the way you write the general solution of the non homogenous equation. So, if y is the solution of the non homogenous equation then you can write y as $y_h(x) + y_p(x)$. I will just put $y(x)$ as $y_h(x) + y_p(x)$, so, $y_h(x)$. So, $y_h(x)$ is a general solution of non homogeneous differential equation this is a general solution of $y_h(x)$ is the general solution of homogeneous differential equation and $y_p(x)$ is any particular solution of non homo of the non homogeneous equation and when I say it can be any particular solution the word any is very important you can choose any particular solution and you can write the general solution is that.

Now, if you remember when we did homogeneous equations we said that you know you can write you can write different basis for the same equation you can write it in terms of different bases. So, same way I mean there are different ways to write the general

solution and therefore, you can choose any particular solution of the non homogenous equation and that will give a; that we give a general solution of the non homogenous equation.

So, just an example of this; so what is important is that we are getting a general solution of the non homogenous differential equation which will have this will have 2 arbitrary constants. Now the general solution of the homogenous differential equation will also have 2 arbitrary constants, but this particular solution will have no arbitrary constants. So, I think it is best if we look at an example just to illustrate this point. So, the 2 arbitrary constants for this for y came entirely from y h.

(Refer Slide Time: 05:55)

The slide is titled "General Solution" and features the NPTEL logo on the left and a circular institutional logo on the right. The handwritten content includes:

- The differential equation: $y'' + 4y = 4$
- The homogeneous solution: $y_h = C_1 \cos 2x + C_2 \sin 2x$
- The general solution: $y = C_1 \cos 2x + C_2 \sin 2x + 1$
- The particular solution found by inspection: $y_p(x) = 1$
- A note: "How to choose $y_p(x)$? Try based on $C(x)$ (RHS of Nonhomogeneous Equation)"
- The general form of a non-homogeneous equation: $y'' + A(x)y' + B(x)y = C(x)$
- A table for choosing trial functions $y_p(x)$ based on the form of $C(x)$:

$C(x)$	e^{ax}	x^n	$\sin wx$ $\cos wx$	$e^{ax} \sin(wx)$ $e^{ax} \cos(wx)$
Trial $y_p(x)$	Ce^{ax}	$C_0 + C_1x + C_2x^2 + \dots + C_nx^n$	$C_1 \sin wx + C_2 \cos wx$	$e^{ax} [A \sin wx + B \cos wx]$
- A concluding note: "Practical and useful method."

So, let us look at an example now. So, suppose you have the differential equation $y'' + 4y = 4$ it is a simple differential equation and in this case you can see that the general solution of this is given by y is equal to. So, this is y double. So, if you look at the homogeneous equation. So, y_h now this is homogeneous equation you have $y'' + 4y = 0$ and the general solution of that will be a sum of $\cos 2x$ and $\sin 2x$. So, I can write it as $C_1 \cos 2x + C_2 \sin 2x$. So, this is my y_h , it has 2 arbitrary constants.

Now, you need to find a y_p , you need to find one particular solution and you see that there is a 4 on the right. So, if y equal to 1 then this term will become 4 and y'' of 1 is 0. So, you will get 4 equal to 4. So, particular solution y_p of x just choose

as one just by inspection we will come later to show you how it is possible to choose this in a more reasonable way, but if you just use this just by inspection we can choose this as the particular solution

So, the general solution y looks like $C_1 \cos 2x$ plus $C_2 \sin 2x$ plus 1 that is the general solution of this of this differential equation and you can verify this. So, suppose you just suppose you just substitute this in this equation what you will get is exactly that you can see that this will clearly satisfy this differential equation. So, what we have shown is that how you can get a general solution of a non homogeneous differential equation from the general solution of the homogeneous differential equation and one particular solution.

Now, how do you choose? So, in this case we just saw we and we decided what y_p was. So, how do you choose y_p in general now the idea here is that you try based on C of x based on C of x which is the right hand side of non homogeneous equation? So, what I mean is if you; your equation looks like $y'' + a y' + b y = C(x)$ this thing equal to 0 if your homogeneous equation and it and when it is not equal to 0 you have to worry about the non homogeneous equation.

So, your choice of y_p depends on what $C(x)$'s and a general recipe to calculate y_p is to choose it based on C or based on $C(x)$. So, I will just make a small chart here. So, I will write $C(x)$ out here and I will write trial y_p of x . So, so what I will show you, I will just make a chart with various choices.

So, suppose my $C(x)$ looks like e^{ax} then my trial will also be some $C e^{ax}$. So, you just take e^{ax} multiplied by some constant that would be my trial function suppose on the other hand is my $C(x)$ looks like x^n then my trial function will be will look like a polynomial in x . So, I take it as I take it as $C_0 + C_1 x + C_2 x^2 + \dots + C_n x^n$ if my $C(x)$ is just a power of x I try with these constants and then I substitute in the equation and then I will find out what the values of these constants should be.

Similarly if you have $\sin \omega x$ or $\cos \omega x$ in either case you just take your trial function as $C_1 \sin \omega x + C_2 \cos \omega x$ and then you substitute in the differential equation and then you find out the values of C_1 and C_2 , if you had a product of e^{ax} times $\sin \omega x$ or $\cos \omega x$. Then again your trial function will also look like will look like e^{ax} and then you have a $\sin \omega x$

x plus $b \cos \omega x$. So, you try this form can you substitute in this equation and then you calculate your; you calculate the values of A and B . So, what I am showing you here is a recipe of how you choose your particular solution just by looking at looking at what your form of $C x$'s.

Now, this is this works often, but there is also a more and we will see examples this is a very practical method. So, I will emphasize that this is a very practical and useful method then because then when it works quite well; however, a formal method of calculating y_p is, what is called variation of parameters. So, this is a formal method of no trial. So, no trial function, so, you do not use any trial function you just take whatever your C of x s and you solve this.

(Refer Slide Time: 12:31)

Variation of parameters
 Formal method \rightarrow No trial function

Homogeneous DE $y_h(x) = c_1 y_1(x) + c_2 y_2(x)$

Nonhomogeneous DE solution $y(x) = u(x) y_1(x) + v(x) y_2(x)$

$$y' = u y_1' + u' y_1 + v y_2' + v' y_2$$

$$y'' = u y_1'' + 2u' y_1' + u'' y_1 + v y_2'' + 2v' y_2' + v'' y_2$$

$$[u y_1'' + 2u' y_1' + u'' y_1 + v y_2'' + 2v' y_2' + v'' y_2] + A(x) [u y_1' + u' y_1 + v y_2' + v' y_2] + B(x) [u y_1 + v y_2] = C(x)$$

$$u(y_1'' + A(x)y_1' + B(x)y_1) = 0$$

$$2u' y_1' + u'' y_1 + 2v' y_2' + v'' y_2 \neq A(x)(u' y_1 + v' y_2) = C(x)$$

So, let us take an example or let us see what the formal method is, so the formal method is your suppose your y_h of x is equal to this is solution of homogeneous equation the corresponding homogeneous equation suppose this solution you wrote it as a form $C_1 y_1(x) + C_2 y_2(x)$ then the non homogeneous equation de solution what you write it is you write it as y of x is equal to u of x times y_1 of x plus v of x times y_2 of x .

So, So, instead of just C_1 and C_2 being constants for the non homogeneous equation you imagine that you replace it by some function u and this by some function v . So, again once you do this then you have to calculate what is u and v . So, this is just like the variation of parameters that we used in the case of in the case of first order differential

equations. So, if you will take this and substitute in the original differential equation what you will get. So, let us just work out what happens when you substitute. So, you will get y' is equal to $u y' + u' y + v y'' + v'$ and then you calculate y'' say that will be $u y'' + 2 u' y' + u'' y + v y'' + 2 v' y' + v'' y$.

So, you have this and when you substitute this in your non homogeneous equation then what you will get is that your instead of y'' you have you have all these terms. So, you have $u y'' + 2 u' y' + u'' y + v y'' + 2 v' y' + v'' y$. So, this is your y'' and then you have you have plus a of x into y' y' is nothing, but $u y' + u' y + v y'' + v'$.

So, remember this whole thing was your $y'' = a$ of x times y' and then you have plus b of x times y , y is nothing, but $u y' + v y'' = C$ of x . So, what we did was we just took this trial form of y and we substituted in this differential equation now you have to look at it term by term, but what you will see is the following what you can see immediately remember y_1 and y_2 are solutions of the homogeneous equation. So, y_1 and y_2 satisfy the homogenous differential equation. So, you can see that if you look at this term look at b times y_1 . So, there is a u in front then you have y_1'' with a u in front and then you have a times y_1' with a u in front.

So, these 3 terms are just u times. So, if I just write this as u times $y_1'' + a$ of x $y_1' + b$ of x y_1 . So, that is what you get when you add these 3 terms these 3 terms that are underlined in light blue colour and now you can see that the term in the bracket is equal to 0 because y_1 satisfies the homogeneous equation. So, these 3 terms add up to 0.

Similarly, you can look at you can look at this term and then you can look at the corresponding terms here which looks like this and here you will have a term $v y_2''$. So, those 2 also add up to 0. So, then what you are left with after this is the following you are left with an equation that looks like this. So, you have $2 u' y_1' + u'' y_1 + 2 v' y_2' + v'' y_2$ this is equal to plus a of x times $u' y_1' + v' y_2'$ equal to C of x .

(Refer Slide Time: 19:21)

Handwritten notes on a whiteboard showing the derivation for variation of parameters:

Homogeneous DE: $y_h(x) = c_1 y_1(x) + c_2 y_2(x)$

Nonhomogeneous DE solution: $y(x) = u(x) y_1(x) + v(x) y_2(x)$

$y' = u y_1' + u' y_1 + v y_2' + v' y_2$

$y'' = u y_1'' + 2u' y_1' + u'' y_1 + v y_2'' + 2v' y_2' + v'' y_2$

$[u y_1'' + 2u' y_1' + u'' y_1 + v y_2'' + 2v' y_2' + v'' y_2] + A(x)[u y_1' + u' y_1 + v y_2' + v' y_2] + B(x)[u y_1 + v y_2] = C(x)$

$u(y_1'' + A(x)y_1' + B(x)y_1) = 0$

$2u' y_1' + u'' y_1 + 2v' y_2' + v'' y_2 \neq A(x)(u' y_1 + v' y_2) = C(x)$

Look for solutions that satisfy $u' y_1 + v' y_2 = 0$

'1

At the bottom of the slide, there is a logo on the left and a circular logo on the right. The text "Variation of parameters" is partially visible at the bottom center.

So, notice what we when we did this we got entirely rid of the b term and we are just left with this now actually even this itself is not that straightforward to solve because you have you have u and v and in general you cannot solve this straightforwardly, but you can do one thing you can look for solution. So, here is a trick that we use. So, we look for solutions for solutions that satisfy $u' y_1 + v' y_2 = 0$. So, this term that multiplies a will go to 0.

So, we look for solutions that satisfy this identity and now. So, what this gives you is the following 2 equations.

(Refer Slide Time: 19:54)

Variation of parameters

$$u'y_1 + v'y_2 = 0 \quad \text{--- (1)}$$

$$2u'y_1' + u''y_1 + 2v'y_2' + v''y_2 = C(x) \quad \text{--- (2)}$$

1st derivative of (1), $u''y_1 + u'y_1' + v''y_2 + v'y_2' = 0 \quad \text{--- (3)}$

$$(2) - (3) \rightarrow u'y_1' + v'y_2' = -C(x) \quad \text{--- (4)}$$

$$(1) \Delta (4) \quad u' = \frac{\begin{vmatrix} 0 & y_2 \\ C & y_2' \end{vmatrix}}{\begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}} \quad v' = \frac{\begin{vmatrix} y_1 & 0 \\ y_1' & C \end{vmatrix}}{\begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}}$$

Denominator = $W = y_1y_2' - y_1'y_2$
(Wronskian)

So, the first equation is $u' y_1 + v' y_2 = 0$ and the second equation looks like so. So, now, my second equation will have the form $2 u' y_1' + u'' y_1 + 2 v' y_2' + v'' y_2 = C(x)$.

So, this may look a little complicated, but actually the solution of this is fairly straightforward now once you give once you impose this condition if you take the first derivative of the of the first equation. So, let me call this equation one and let me call this equation 2. So, if you take first derivative of one then you get $u'' y_1 + u' y_1' + v'' y_2 + v' y_2' = 0$ and you can see that in this equation you have you though in the second equation you have $u'' y_1$ and instead of single $u' y_1$, you have twice $u' y_1$.

So, now, if you just subtract the second and third equation, so if you just subtract equation 2 minus 3 then you get $u' y_1' + v' y_2' = -C(x)$ and let me call this equation 4, now if you just look at 1 and 4, now this looks like $u' y_1 + v' y_2 = 0$ and $u' y_1' + v' y_2' = -C(x)$.

Now, you can immediately. So, this should be equal to sorry this is not 0 this is; this should be $C(x)$ this should be $C(x)$ this quantity remember what is equal to $C(x)$. So, and now from the first derivative what we will get on the right hand side is not 0, but we will get $d C(x) / dx$. So, finally, what you get is this is equal to $d C(x) / dx$.

and this is very nice because what if you look at one and 4 they if you if you just look at these 2 then using your matrix methods you can write u prime is equal to in terms of determinant. So, what you will get is 0, I will just call it C prime and then you have y 2 y 2 prime. So, this determinant divided by y 1 y 2 y 1 prime y 2 prime.

So, what I did was I just looked at 1 and 4 as 2, 2 as a system of linear equations for variables u prime and v prime. So, then you immediately get this and you also get v prime is equal to you will get y 1 y 1 prime 0 C prime and you will get y 1 y 2 y 1 prime y 2 prime should just be C of x, this should not be d C by d x it should just be C of x.

So, because we took a derivative of one, so what I wanted to emphasize is that is that this should be C of x and so and so I get my u prime and v prime in this form and you can write u as the integral of this whole thing this denominator this denominator.

(Refer Slide Time: 24:45)

Handwritten mathematical derivation for variation of parameters:

1st derivative of (1), $u''y_1 + u'y_1' + v''y_2 + v'y_2' = C(x)$ — (4)

(2) - (3) $\rightarrow u'y_1' + v'y_2' = -C(x)$ — (4)

(1) & (4)

$$u' = \frac{\begin{vmatrix} 0 & y_2 \\ C & y_2' \end{vmatrix}}{\begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}} \quad v' = \frac{\begin{vmatrix} y_1 & 0 \\ y_1' & C \end{vmatrix}}{\begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}}$$

Denominator = $W = y_1 y_2' - y_1' y_2$
(Wronskian)

$$u' = -\frac{C y_2}{W} \quad v' = \frac{C y_1}{W}$$

NPTEL

Variation of parameters

So, the denominator is referred to as w or the Wronskian and this is basically y 1 y 2 prime minus y 1 prime y 2 and so you can write your; you can write your u and v in the following form. So, what you will get is u prime is equal to minus C y 2 by w and v prime is equal to C y 1 by w and so what this variation of parameters gives you it gives you u equal to integral minus C y 2 by w d x and v equal to integral C y 1 by w d x.

(Refer Slide Time: 25:16)

Variation of parameters

$$u = \int -\frac{C y_2}{w} dx \quad v = \int \frac{C y_1}{w} dx$$
$$y = u y_1 + v y_2$$

SOLVED Non homogeneous DE

So, we can get; we calculated u and v and this basically so, once we have u and v we can write y is equal to $u y_1$ plus $v y_2$. So, we have solved non homogeneous differential equation. So, if you know y_1 and y_2 of the homogeneous equation then you can solve the non homogeneous differential equation using this method of variation of parameters.

So, in the next class, I will discuss some practice problems and then in the next module that is the following week, we will start looking at how to get the solutions of the homogeneous equation, how what is the general method of getting the solutions of the homogeneous equation and this will lead us to something called the power series method.
