Critical Points of Functions

In today's lecture, I will be talking about the classification of critical points of functions and I will be elaborating on some of the topics that we did in the last two lectures. We saw how to understand maxima and minima of functions in very simple terms. Now, you might have functions that are slightly more complicated than the simple functions that we looked at. So, it is good to have a general idea of how to classify the critical points of functions. So, I will first talk about functions of a single variable and then I will talk about functions of two variables, but you can extend these arguments to functions of more than two variables also, ok.

(Refer Slide Time: 01:03)

Lecture 3: Critical Points of functions

$f(x)$ Critical Point $\Rightarrow f'(x_0) = 0$
 x_0

If: $f''(x_0) > 0$, x_0 is a minimum (local)
 $f''(x_0) < 0$, x_0 is a maximum (local)
 $f''(x_0) = 0$, look at $f'''(x_0)$
 $f'''(x_0) > 0 \Rightarrow$ minimum
 $f'''(x_0) < 0 \Rightarrow$ maximum

$\frac{\partial f}{\partial x} \Big|_{x=x_0}$

The image shows a handwritten note on a digital whiteboard. The title is "Lecture 3: Critical Points of functions". Below the title, it defines a critical point as where the first derivative is zero: $f'(x_0) = 0$. It then lists conditions for local minima and maxima based on the second derivative: $f''(x_0) > 0$ implies a local minimum, and $f''(x_0) < 0$ implies a local maximum. For the case where $f''(x_0) = 0$, it instructs to look at the third derivative: $f'''(x_0) > 0$ implies a minimum, and $f'''(x_0) < 0$ implies a maximum. To the right of the text is a graph of a function with multiple peaks and valleys. Dashed vertical lines connect the local maxima and minima on the graph to the x-axis. The NPTEL logo is visible in the bottom left corner of the whiteboard.

So, let us look at a function of a single variable. So, if you have f of x now a critical point. So, critical point implies f prime of x_0 equal to 0. So, then x_0 is a critical point. So, x_0 becomes a critical point if the derivative at x_0 equal to 0. So, f prime of x_0 is a short notation for $\frac{df}{dx}$ evaluated at x equal to x_0 . Now, that is a critical point. Now, there can be different critical points. So, to know nature of critical point, you look

at $f''(x_0) > 0$. So, if $f''(x_0)$ is greater than 0, then x_0 is minimum and we should emphasize that this is local minimum suppose to a global minimum. So, suppose you have a function what we said is that your function can have several minima.

So, it can have a function like this. So, now each of these points is a local minimum. So, each of these points, the derivative is 0. Similarly you can have local maxima also. So, each of these is local maxima. Now, the global minimum of this function is right here. This is the minimum value of the function, but the first derivative will be 0 for each of these. Each of these points will also satisfy minimum conditions. If $f''(x_0)$ is less than 0, then x_0 is maximum and again local maximum if $f''(x_0)$ equal to 0, then there are a lot of things that are possible.

What you have to do is look at $f'''(x_0)$, ok. Then, you use the same condition. So, what you will see is $f'''(x_0) > 0$ implies minimum, local minimum. $f'''(x_0) < 0$ implies local maximum. This is if the second derivative is 0. If the second derivative is 0, then you have to look at the third derivative. If the third derivative is 0, you look at the fourth derivative, ok.

(Refer Slide Time: 03:54)

If $f'(x_0) = 0$,
 Look at sign of 1st nonzero
 derivative at x_0

What about $f(x, y)$?
 CRITICAL POINT $\Rightarrow f_x(x_0, y_0) = \frac{\partial f}{\partial x} \Big|_{x_0, y_0} = 0$
 $f_y(x_0, y_0) = \frac{\partial f}{\partial y} \Big|_{x_0, y_0} = 0$

$f(x) = x^3$
 At $x = 0$
 $\frac{\partial f}{\partial x} = 0$
 $\frac{\partial^2 f}{\partial x^2} = 0$
 $\frac{\partial^3 f}{\partial x^3} = 6 \neq 0$
 Local minimum

So, now what are the kind of functions that can have a second derivative 0, but a third derivative. So, you could have a function something like that comes down and then, it

goes almost flat for sometime. So, it goes flat enough that the second derivative is 0 and then, it goes up again. Suppose you just take a function like x minus x cube, ok.

Now, you know I will just say x plus x cube or just x cube for that matter. Now, at x equal to 0 $\frac{df}{dx}$ equal to zero, no space here. This is f of x equal to x minus x cube. So, at x equal to 0 $\frac{df}{dx}$ equal to 0 because $\frac{df}{dx}$ let say 1. I just say x cube. Let me just put it as x cube. So, let us just take x cube for example. So, at x equal to 0 $\frac{df}{dx}$ is equal to 0 $\frac{d^2f}{dx^2}$ equal to 0 and $\frac{d^3f}{dx^3}$ equal to 6 not equal to 0. This is at x equal to 0 at x equal to 0 at x equal to 0 $\frac{df}{dx}$ is $3x^2$ because x equal to 0 if that is 0 $\frac{d^2f}{dx^2}$ is $6x$ which is equal to 0 at x equal to 0, but the third derivative is not 0, ok.

So, clearly this is a local minimum. So, the point is you have to look at the first non-zero derivative. So, if $f'(x_0) = 0$, then look at a sign of first non-zero derivative at x_0 and then, you can identify maximum or minimum. That is a condition for identifying maximum or minimum. Of course, if all derivatives are 0, then the function is just constant. So, that is a trivial case which I won't bother about.

So, this is what you do with functions of single variables. Now, what about functions of many variables functions of 2 variables? So, the definition of critical point implies f_x of x_0, y_0 equal to 0 and f_y of x_0, y_0 equal to 0 and this is very important. Both the condition should be satisfied. So, this is very important which is $\frac{df}{dy}$ at x_0, y_0 equal to 0. So, that is the condition for the critical point.

(Refer Slide Time: 07:43)

The image shows a digital whiteboard with handwritten mathematical notes. At the top, the Hessian determinant is defined as $D(x_0, y_0) = f_{xx} f_{yy} - f_{xy}^2$ evaluated at (x_0, y_0) , labeled as (HESSIAN). Below this, the second partial derivative $\frac{\partial^2 f}{\partial x^2}$ is written in red. A list of four cases for classifying critical points is provided:

- (i) If $f_{xx} > 0$ and $D(x_0, y_0) > 0 \rightarrow$ Minimum
- (ii) If $f_{xx} < 0$ and $D(x_0, y_0) > 0 \rightarrow$ Maximum
- (iii) If $D(x_0, y_0) < 0$, saddle point
- (iv) If $D(x_0, y_0) = 0$, look at higher derivatives

Now, you can ask the same question when is it a maximum, when is it a minimum? So, in order to identify maximum or minimum of a function of many variables, what you do is you define $f_{xx} f_{yy}$ minus $f_{xy} f_{xy}$ square and call this as d of $x_0 y_0$. So, you are evaluating this at $x_0 y_0$. All this each of these derivatives. So, this is nothing, but double square f by double x square evaluated at $x_0 y_0$. So, this quantity D , this object D is sometimes called the Hessian. Now, the way you classify the critical points is you say you look at the first case and if f_{xx} is greater than 0 and d of $x_0 y_0$ is greater than 0, then this is minimum and it is a local minimum again. Everything is local minima.

Now, the second case is if f_{xx} is less than 0 and d of $x_0 y_0$ is greater than 0, then it is a local maximum. The third case is, if d is greater than 0, you can have two cases where f_{xx} is greater than 0 or it is less than 0. Now, notice the second term in d xy . This is always greater than 0, this is greater than 0, greater than or equal to 0 because it is a square. So, if $x x$ if d is greater than 0 and f_{xx} is greater than 0, then automatically f_{yy} has to be greater than 0. Similarly, if d is greater than 0, again if f_{xx} is negative, then f_{yy} also has to be negative. So, you can use the same condition even for f_{yy} . This is only if d is greater than 0. The third case is if d of $x_0 y_0$ is less than 0, then it is a saddle point. If this is less than 0, then this point is a saddle point.

Now, notice each of these can be greater than 0. $f_{xx} f_{yy}$ can all be greater than 0 and $f_{xy} f_{xy}$ can also be greater than 0, but if this d is less than 0, then it becomes a saddle point.

The fourth case is if d of x_0, y_0 is equal to 0, then we have to look at higher derivatives. So, what I want to say is that you know you have to look at various partial derivatives in order to decide what kind of critical point you have. So, now let me just illustrate this with a very simple example of a function and we will look at this function and we will identify and list all the critical points and then, we will classify them, ok.

(Refer Slide Time: 10:54)

Example: $f(x,y) = x^3 + y^3 - x - y$

$f_x(x_0, y_0) = 3x_0^2 - 1$ $f_y(x_0, y_0) = 3y_0^2 - 1$

$3x_0^2 = 1 \Rightarrow x_0 = \pm \sqrt{\frac{1}{3}}$ $y_0 = \pm \sqrt{\frac{1}{3}}$

4 CPs: $(\frac{1}{\sqrt{3}}, \frac{1}{\sqrt{3}}) \rightarrow D > 0, f_{xx} > 0$ Minimum

$(\frac{1}{\sqrt{3}}, -\frac{1}{\sqrt{3}})$ } $D < 0$ Saddle points

$(-\frac{1}{\sqrt{3}}, \frac{1}{\sqrt{3}})$ }

$(-\frac{1}{\sqrt{3}}, -\frac{1}{\sqrt{3}}) \rightarrow D > 0, f_{xx} < 0$ Maximum

$f_{xx} = 6x_0$ $f_{yy} = 6y_0$
 $f_{xy} = 0$
 $D(x_0, y_0) = 36x_0y_0$

Plotting Software: Matlab, Mathematica, Maple, origin etc

So, let us just take a simple example. So, suppose I take f of x, y is equal to x cube plus y cube minus x minus y . So, what are the critical points? So, if you want to identify the critical points, what we will say is f_x of x_0, y_0 is equal to x_0 square minus 1 and f_y of x_0, y_0 . So, the first term is independent of y . So, the second term will give $3y_0$ square and then, this term x won't contribute the derivative with respect to y be minus 1.

So, now at the critical points $3x_0$ square equal to 1 implies x_0 equal to plus or minus square root of 1 by 3 and y_0 equal to plus or minus square root of 1 by 3-4 critical points. What are the four? So, the first one is 1 by root 3, 1 by root 3, the second one is 1 by root 3 minus 1 by root 3, third one is minus 1 by root 3, 1 by root 3 and the fourth one is minus 1 by root 3 minus 1 by root 3. This is the value of x_0 and y_0 . So, you have these four critical points.

Now, let us try to classify them. So, let first calculate f_{xx} . So, I will write here and this f_{xx} . So, first I will write the general derivative and then, I will substitute the critical points. So, f_{xx} is equal to $6x_0$, f_{yy} is equal to $6y_0$, f_{xy} is equal to 0. So, therefore, now

you can calculate $d^2f(x_0, y_0)$ is equal to $36x_0y_0$. So, now in the first case and the fourth case, d^2f is greater than 0.

Now, if you look at the second if you look at f_{xx} for this, so f_{xx} is greater than 0. So, this is clearly minimum where f_{xx} is less than 0 and this is maximum and these two points have $d^2f < 0$ for these two points and these are saddle points. So, just by looking at the function and taking its derivatives, we identified where it is maximum, where it is minimum and which are the saddle points of this function, ok.

Now, you can go ahead and if you want you can actually plot this function using standard plotting software. So, you can use plotting software especially in multi-dimensional plots. So, full of plotting software such as Matlab Mathematica, Gnuplot, Origin etcetera; using any of these plotting software, you can actually plot this function and you can actually visualize some of these maxima and minima. So, I encourage you to do this and this will help you get a better understanding of these critical points. So, I will conclude this lecture here.

So, in the next lecture we will talk about Lagrange's method of undetermined multipliers.

Thank you.
