Two- Dimensional Wave Equation, Bessel Functions Part 1

In the last lecture we saw a technique of solving partial differential equations, which we refer to as the separation of variables. And what we saw is that by using this technique a partial differential equation can be converted to a set of ordinary differential equations. Now what I want to do is an application of this method, and this method I will apply it to a problem which is called the wave equation.

And we will apply it in 2 dimensions. And what I want to emphasize through this method, is that, is that I mean first I want to illustrate how this method work. And then the next thing that I want to do is to really show you how do doing this 2 dimensions based on the boundary conditions, you will get solutions that look very different, even though they are solutions to the same physical problem that of a wave going in 2 dimensions.

So, what we will see is that by imposing the boundary conditions, we will change the nature of the solution, and we already saw in the first lecture that the geometry of the problem decides on the coordinates that you use. And the coordinates that you use we will actually affect the solutions. So, this is what I will show in today's lecture. So, today's lecture will be a slightly longer lecture. So, it will be actually substantially longer. So, it will be almost one hour lecture. So, after this we will go straight to the final lecture of the module. So, this module will have only 4 lectures and today's lecture will be a slightly longer lecture.

So, let us start this module will start by writing down the 2 dimensional wave equation. So, in general I can write the wave equation in the following form right.

(Refer Slide Time: 02:06)

Lecture 3: Two-dimensional Wave Equation, Bessel Functions
(LONG LECTURE)

$$\nabla^2 u(\vec{r}, t) = \frac{1}{v^2} \frac{\partial^2 u(\vec{r}, t)}{\partial t^2} \quad v = \text{velocity of wave}$$

$\vec{r} \equiv (x, y) \equiv (r, \theta)$

In Cartesian coordinates

$$\frac{\partial^2 u(x, y, t)}{\partial x^2} + \frac{\partial^2 u(x, y, t)}{\partial y^2} = \frac{1}{v^2} \frac{\partial^2 u(x, y, t)}{\partial t^2}$$

In Plane Polar coordinates $[x = r \cos \theta, y = r \sin \theta; 0 \leq r < \infty, 0 \leq \theta < 2\pi]$

$$\frac{\partial^2 u(r, \theta, t)}{\partial r^2} + \frac{1}{r} \frac{\partial u(r, \theta, t)}{\partial r} + \frac{1}{r^2} \frac{\partial^2 u(r, \theta, t)}{\partial \theta^2} = \frac{1}{v^2} \frac{\partial^2 u(r, \theta, t)}{\partial t^2}$$

Let me write u as the amplitude of the wave. So, if I write u as the amplitude of the wave. Then u is a function of I will just say r , r is a 2 dimensional vector and is a function of time. So, r has r is composed of coordinates x and y or equivalently you can write it in terms of r and θ , in terms of either polar coordinates or Cartesian coordinates. Then what the wave equation does is it relates the Laplacian, this is a Laplacian in 2 dimensions of u , u of r t it relates it to the second derivative with respect to time t square of u of r t and between these 2 there is a factor the factor is related to the velocity of the wave. So, v square v is the velocity of the wave ok.

So, this is the, this is a general 2 dimensional wave equation. Now in Cartesian coordinates this takes a form second derivative with respect to X of u of x y t by $\text{d}u$ x square, plus second derivative of u of x y t with respect $\text{d}u$ y square this is 1 by v square $\text{d}u$ square by $\text{d}u$ t square u of x y t .

So, this is what the wave equation looks like in Cartesian coordinates, in plane polar coordinates, where we say and just to remind you plane polar coordinates have x equal to r cosine of θ and y equal to r sin of θ and you know r , r goes from 0 to infinity and θ goes from 0 to 2π . So, this is the plane polar coordinate. And so in these coordinates what this becomes it takes a following form. So, it becomes $\text{d}u$ square u of r θ t divided by $\text{d}u$ r square plus 1 over r $\text{d}u$ u of r θ t divided by $\text{d}u$ r plus 1

over r square dou square u of r theta t divided by dou t square is equal to 1 over v square dou square u of r theta t divided by dou t square.

So, we have these 2 forms one is in Cartesian coordinates and one is in plane we in plane polar coordinates. Now let us first look at the case. So, the wave equation we have we have this xy coordinates.

(Refer Slide Time: 05:47)

Rectangular membrane
 $u(x,y,t) = 0$ if
 $x \geq +\frac{L_x}{2}$ or $x \leq -\frac{L_x}{2}$
 $y \geq +\frac{L_y}{2}$ or $y \leq -\frac{L_y}{2}$

$\frac{\partial^2 u}{\partial x^2} + \frac{\partial^2 u}{\partial y^2} = \frac{1}{v^2} \frac{\partial^2 u}{\partial t^2}$

$u(x,y,t) = U(x,y)T(t)$ Separation of spatial and temporal coordinates

$\frac{1}{U} \left[\frac{\partial^2 U}{\partial x^2} + \frac{\partial^2 U}{\partial y^2} \right] = \frac{1}{v^2 T} \frac{\partial^2 T}{\partial t^2} = k$ (constant)

$\frac{\partial^2 T}{\partial t^2} = kv^2 T = -\lambda^2 T$ $\lambda = kv^2$
 ↳ Basic phy

This is the 2 dimension of space. So, 2; so this is a 2 dimensional space and the wave equation is something that is satisfied in this 2 dimensional space.

Now we look at 2 examples the first example, we look at where the boundary conditions are along x and y . So, what will say is that you have a rectangular region where the wave equation is satisfied and just for convenience I will take this rectangular region to be symmetric about the over the axis you do not have to. So, we have this rectangular region. Let me call this minus L_x to plus L_x , L_x by 2. Therefore, the length along the x direction is L_x . And let me call the y coordinate is minus L_y by 2 this becomes plus L_y by 2. So, this is minus L_x by 2 L_y by 2. This is L_x by 2 L_y by 2. So, these are the coordinates of these 2 points.

So, what I am saying is that this distance along the Y direction is L_y along the x direction is L_x . So, this is L_x and this is L_y . So, what I want to do is I want to say that the wave equation is only satisfied in this region and outside this region the wave

equation is not satisfied. In other words what I am going to say is that $u(x, y, t) = 0$ if x is greater than or equal to $-L_x/2$ or x is less than or equal to $L_x/2$. And y is greater than or equal to $-L_y/2$ or y is less than or equal to $L_y/2$.

So, in all these cases the u goes to 0. So, basically outside this region outside this rectangular region u is exactly equal to 0. So, this is for the rectangular membrane. And the why I call it a membrane is because there is a wave equation. So, if you just had a 1 dimensional wave equation that would look like a string that would look like oscillations like the vibrations of a string. If you have a 2 dimensional region that is like a rectangular membrane. So, in this case we have fixed the boundary. So, we have fixed the edges of the rectangle. So that the u goes to 0 at those edges and now we want to solve what is the equations of these waves of these waves inside this region.

So now let us let us look inside the region we have we have $\nabla^2 u = \frac{1}{v^2} \frac{\partial^2 u}{\partial t^2}$. So, what will do first is $u(x, y, t) = U(x, y) T(t)$ this is a first separation of variables that we are going to use. So, separation of spatial and temporal coordinates. So, in other words the t is the time and these 2 are spatial coordinates.

So, we separated the spatial and temporal coordinates. And when you do this then when you make the substitution in the equation then what you will get is you will get $\nabla^2 u = \frac{1}{v^2} \frac{\partial^2 u}{\partial t^2}$. So, we did the substitution we divided by $u T$ and accordingly you will get such an equation. Now the right hand side is a function only of t the left hand side is a function only of x and y .

So, therefore, each of these should be equal to a constant. And so we will just call this k constant. So now, the temporal part is very straightforward. So, we have $\frac{\partial^2 T}{\partial t^2} = -k v^2 T$. And we will call we will set this equal to $-\lambda^2 T$ where λ is equal to $k v$. So, we assume that k is negative and $k v^2$ is we write it as $-\lambda^2$. This is I mean there is a there is a very intuitive reason why this should be true. There is a basic physical reason. And you can you can sort of understand this because this looks like a harmonic oscillator. And if you if your harmonic oscillator had had it has to have it has to have the it has to have a

frequency then this should be a negative sign. So, if it is not a negative sign it just becomes exponential function. So, then this t will just be exponential functions it would not represent a wave. So, there is a basic physical reason why this should be negative.

Now, what you will get if you solve this equation this is a straightforward equation, you will get t is equal to.

(Refer Slide Time: 12:02)

Handwritten mathematical derivation on a whiteboard:

$$T(t) = a_0 e^{i\lambda t} + a_1 e^{-i\lambda t}$$

or

$$T(t) = a_0 \cos(\lambda t) + a_1 \sin(\lambda t)$$

$$\frac{\partial^2 U}{\partial x^2} + \frac{\partial^2 U}{\partial y^2} = -\lambda^2 U$$

$$U(x,y) = X(x) Y(y) \quad \text{2nd Separation}$$

$$\frac{1}{X} \frac{d^2 X}{dx^2} + \frac{1}{Y} \frac{d^2 Y}{dy^2} = -\lambda^2$$

$$\frac{d^2 X}{dx^2} = -\lambda_1^2 X \quad ; \quad \frac{d^2 Y}{dy^2} = -\lambda_2^2 Y \quad \lambda_1^2 + \lambda_2^2 = \lambda^2$$

$$X = b_0 \cos \lambda + b_1 \sin \lambda t \quad ; \quad Y = d_0 \cos \lambda t + d_1 \sin \lambda t$$

So, let me put the time explicitly, T at time 0 and t more because you can have either plus or minus lambda. So, I can write as $a_0 e^{i\lambda t} + a_1 e^{-i\lambda t}$ or $T(t) = a_0 \cos(\lambda t) + a_1 \sin(\lambda t)$. Now these two are not the same. You can write it in either of these forms. But it is basically either a sum of sines and cosines or a sum of exponentials with imaginary coefficients.

Now, let us look at the other equation. So, the other equation has the form $\frac{\partial^2 u}{\partial x^2} + \frac{\partial^2 u}{\partial y^2} = -\lambda^2 u$. Now this is not separated yet. So, you assume that $u(x,y) = X(x) Y(y)$. So, this is the next second separation of variables. So, we are separating the x and y parts. And now what you will get is you will get if you substitute this and you again divide by $X Y$, what you will get is $\frac{1}{X} \frac{d^2 X}{dx^2} + \frac{1}{Y} \frac{d^2 Y}{dy^2} = -\lambda^2$.

So, each of these is each of these has to be con this give the first term depends only on x next second term depends only on y, a right hand side is a constant. So, if you have a function of x that depends and a function of y and they add up to give a constant then each of these should be independent of x and y each of these should be a constant. So, what you have is 1, what I can write is I can write 2 equations I can write $d^2 x$ by $d^2 x$ square is equal to minus $\lambda^2 x$ and I can write $d^2 y$ by $d^2 y$ square is equal to minus $\lambda^2 y$. So, I have these equations.

Now, each of these I can I can solve this. So, I can write X is equal to $a \cos \lambda t + b \sin \lambda t$ and y is equal to let me call it $d \cos \lambda t + e \sin \lambda t$. So, these are the equations that you have and no sorry. So, this there is there is one point I should I should I am mention I will call this λ_1 . And I will call this λ_2 and what I will say is that $\lambda_1^2 + \lambda_2^2 = \lambda^2$. So this.

So, this has to be a constant it need not be equal to λ . So, it has to be a constant it can be λ_1 . So, I will just call it λ_1 . And this has to be a constant it can be λ_2 : so $\lambda_1^2 + \lambda_2^2 = \lambda^2$ and so λ_1 and λ_2 should satisfy the relation that $\lambda_1^2 + \lambda_2^2 = \lambda^2$ should be equal to λ^2 . And further we are saying that x should be of this form. So, if x is of this form then will have $d^2 x$ by $d^2 x$ square should will give you minus $\lambda_1^2 x$. Similarly if y has this form then we will have $d^2 y$ by $d^2 y$ square equal to minus $\lambda_2^2 y$ ok.

So now we can do more. So now you impose boundary conditions. So, when we impose the boundary conditions, so what will say is that X of minus L x by 2 equal to X of plus L x by 2 equal to 0.

(Refer Slide Time: 16:32)

Impose boundary conditions

$$x\left(-\frac{Lx}{2}\right) = x\left(\frac{Lx}{2}\right) = 0 \Rightarrow \begin{aligned} b_0 \cos\left(-\frac{\lambda_1 Lx}{2}\right) - b_1 \sin\left(\frac{\lambda_1 Lx}{2}\right) &= 0 \\ b_0 \cos\left(\frac{\lambda_1 Lx}{2}\right) + b_1 \sin\left(\frac{\lambda_1 Lx}{2}\right) &= 0 \end{aligned}$$

$$\Rightarrow 2b_0 \cos\left(\frac{\lambda_1 Lx}{2}\right) = 0 \quad \text{Either } b_0 = 0 \text{ or } \cos\frac{\lambda_1 Lx}{2} = 0$$

If $b_0 = 0$, $b_1 \sin\left(\frac{\lambda_1 Lx}{2}\right) = 0 \Rightarrow \sin\left(\frac{\lambda_1 Lx}{2}\right) = 0$

$$\frac{\lambda_1 Lx}{2} = n\pi \quad n = 0, \pm 1, \pm 2, \pm 3, \dots$$

$$\Rightarrow \lambda_1 = \frac{2n\pi}{Lx} \quad n = 0, \pm 1, \pm 2, \pm 3, \dots$$

$$X_n(x) = b_1 \sin\left(\frac{2n\pi}{Lx} \cdot x\right)$$

If $b_0 \neq 0$, $\cos\frac{\lambda_1 Lx}{2} = 0$; $\lambda_1 Lx = \frac{(2n+1)\pi}{2} \quad n = 0, \pm 1, \pm 2, \pm 3, \dots$

So, when we impose this condition what will find is the following. So, first let us So, what we will get is that this implies $b_0 \cos$ minus $\lambda_1 L x$ by 2 plus $b_1 \sin$. So, sin of minus I can write as minus sign. So, I will write minus $\sin \lambda_1 L x$ by 2 equal to 0, and the other equation will get so this is from putting at minus l ; if you put at plus l then you will get $b_0 \cos$ of $\lambda_1 L x$ by 2 plus $b_1 \sin$ of $\lambda_1 L x$ by 2 equal to 0. And if you add these 2 equations we will immediately if you if you add these 2 equations. So, you will get $2 b_0 \cos$ of $\lambda_1 L x$ by 2 equal to 0.

So, either you can have b_0 equal to 0 or $\lambda_1 L x$ by 2 equal to 0, you can have you can have a higher of these cases. Now So, either or cosine of $\lambda_1 L x$ by 2 equal to 0. So, these are the 2 possibilities.

Now, if b_0 equal to 0, then we have then we should have $b_1 \sin \lambda_1 L x$ by 2 should be equal to 0. We should all have this additional condition; so if b_0 equal to 0 now b_1 cannot be 0. So, if b_0 equal to 0 b_1 cannot be 0. So, this implies \sin of $\lambda_1 L x$ by 2 equal to 0 or what you will get is. So, this implies. So, \sin equal to 0 when $\lambda_1 L x$ by 2 is a multiple of π $n \pi$ n equal to 0 plus minus 1 plus minus 2 plus minus 3 and so on. So, whenever this is equal to a integral multiple of π then the \sin of that goes to zero.

So, in this case So, what this implies is that λ_1 is equal to $2 n \pi$ by $L x$, where n can be 0 plus minus 1 plus minus 2 etcetera. So, then the u of or rather X of x is equal to

$b_1 \sin 2n\pi x/L$ into x . So, this is what it looks like. So, λ can take only these values and x can take any of these values, what will do is now this is indexed by n ; so will just put an n here. So, n is 0 plus minus 1 and so on.

So, this is one kind of solution you can get. Now the other solution you will get is if b_0 not equal to 0. So, if b_0 is not equal to 0 then what you get is that, you will get you have to have cosine of $\lambda Lx/2$ equal to 0. And if you have cosine of $\lambda Lx/2$ equal to 0 then what you can get is you will get $\lambda Lx/2$ is equal to $2n + 1/2$ pi. So, it has to be n it has to be a multiple of it has to be an odd integer multiple of pi/2 ok.

So, you will get at $\pi/2, 3\pi/2, 5\pi/2$ and so on. So, n is equal to plus minus 1 plus minus 2 plus minus 3 etcetera. Now in this case in this case I can write so b_0 is not equal to 0. I have I have this additionally and We should have $b_1 \sin \lambda Lx/2$ equal to 0.

(Refer Slide Time: 22:21)

So, this implies we can choose b_1 equal to 0.

Now, now since we already had a condition, since we already had a restriction for λ , we would not have λ satisfy this other relation. So, λ we already chose to be an odd multiple of pi/2. So, it cannot be it cannot be an even multiple of pi. So, therefore, what you will get is the solution X

of x looks like $b_0 \cos\left(\frac{2n\pi x}{L}\right)$. So, what you will get is λ has to be $\frac{2n\pi}{L}$ and so, and so you will get such a relation ok.

So, what are the possibilities? So, in general and then we can write and let me make this in blue. So, X of x is equal to either it is will call it $b_1 \sin\left(\frac{2n\pi x}{L}\right)$ and so on. Or easy or is it equal to or same if you go to $b_0 \cos\left(\frac{2n\pi x}{L}\right)$. So, all these are possible. So, what does say what do these waves look like. So, if I just plot them. So, let me basis minus L , L . So, first let us consider the case lay let us consider the first equation. So, will consider the sin terms let me show it in red and I will just take b_1 and d_0 I will just consider them as one just for convenience. So, this is 1 and minus 1.

So, what does sin if n equal to 0 $\sin\left(\frac{2n\pi x}{L}\right)$ looks like this in this region, it looks like this is when n is sorry, any n equal to 0 is not is not valid. So, n equal to 0 will make the wave function make this function go to 0. So, n equal to 0 should not be taken. In this case you can take n equal to 0. So, for the sin case you cannot take n equal to 0, because n equal to 0 means the function itself will go to zero. But in the case of cosine you can take n equal to 0 because n equal to 0 will still give me π by 2.

So, this is n equal to 1. So, this is a sin with n equal to 1, and then let us, what about sin with n equal to 2? With n equal to 2 the sin will look will look like this, this is the equation. So, this is $\sin\left(\frac{4\pi x}{L}\right)$ $\sin\left(\frac{2\pi x}{L}\right)$ and this is $\sin\left(\frac{4\pi x}{L}\right)$ and so on you can take. So, $\sin\left(\frac{6\pi x}{L}\right)$ will have will have 3 will have 3 completed, I mean I mean 3 oscillations in the x direction and 3 in the Y direction or 3 in the minus x direction.

Now, let us look at the cosine. So, what does the cosine look like? So, I will draw this in blue; so the cosine if you again assume b_0 equal to 1. So, when n equal to 0 then you have cosine of $\frac{\pi x}{L}$. So, when x equal to $\frac{L}{2}$ then this becomes cosine of $\frac{\pi}{2}$ equal to 0. Oh made a mistake, this will be minus $\frac{L}{2}$ plus $\frac{L}{2}$. Now, when x equal to 0 this equal to 1; so it goes so it starts this way and it goes to 0 here, starts this way and goes to 0 here. So, this is for cosine of $\frac{\pi x}{L}$. So, this is cosine of $\frac{\pi x}{L}$.

Now, when you take the next one when you take cosine of $3\pi x$ by Lx , then when x equal to Lx by 2 it goes to a cosine of 3π by 2. So, cosine of 3π by 2. And so what will happen is that it will go it will go to 0 and then it will become negative and then I will go back to 0. So, this will look like this. So, these are what the waves looked like and notice that they all go to 0 at minus Lx by 2 and plus Lx by 2.

Now, I do not need to do the same thing again for the Y direction. So, I will just write So, we will get very similar solutions for the Y directions in Y direction. Now let me just mention one small thing which, which you might recall from your quantum mechanics. So, I will just mention this.

(Refer Slide Time: 30:20)

Suppose we had chosen the range of x and y as $0 \leq x \leq Lx$
and $0 \leq y \leq Ly$

Solutions: $X(x) = a_0 \cos(\lambda_1 x) + a_1 \sin(\lambda_1 x)$

B.C. $X(0) = 0 \Rightarrow a_0 = 0$
 $X(Lx) = 0 \Rightarrow a_1 \sin(\lambda_1 Lx) = 0 \Rightarrow \lambda_1 = \frac{n\pi}{Lx} \quad n = \pm 1, \pm 2, \pm 3, \dots$

$X(x) = a_1 \sin\left(\frac{n\pi}{Lx} x\right) \quad n = \pm 1, \pm 2, \pm 3, \dots$

Familiar form of Particle in a box in Q.M.

$U(x,y,t) = \left(a_0 \cos(\lambda_1 x) + a_1 \sin(\lambda_1 x) \right) \left(b_0 \cos(\lambda_2 y) + b_1 \sin(\lambda_2 y) \right) \left(d_0 \cos(\lambda t) + d_1 \sin(\lambda t) \right)$

$\lambda^2 = \lambda_1^2 + \lambda_2^2$ and $\lambda_1 = \frac{n\pi}{Lx} ; \lambda_2 = \frac{n\pi}{Ly}$

Now suppose we had chosen the range of x and y as 0 less than equal to x less than equal to Lx and 0 less than equal to y less than equal to Ly . Will just take x just to illustrate the point. The solutions would have been X of x equal to a_0 cosine of $\lambda_1 x$, x plus a_1 sin of $\lambda_1 x$. So, we will just look at the x direction and just I will just illustrate this point. Now boundary conditions X of 0 equal to 0 implies a_0 equal to 0 . Because when you put x equal to 0 the sin term goes to 0 . So, will just left b left at a_0 and that has to equal 0 . So that directly implies a_0 is 0 equal to 0 now X of Lx equal to 0 implies a_1 now a_1 cannot be 0 . So, sin of $\lambda_1 Lx$ equal to 0 and this implies λ_1 is equal to $n\pi$ by Lx n equal to n , n cannot be 0 in this case because n equal to 0 will

mean the function itself is $0 \leq n \leq 1, 2, 3, \dots$ and so on ok.

So therefore, we will directly get the solution in this form. So, we directly get the solution of X of x is equal to $a_1 \sin n \pi x / L$ plus $a_2 \cos n \pi x / L$ and so on. So, what we see is that this is this is this is familiar form, form of particle in a box particle in a 1 d box in quantum mechanics. So, what I want to say is that the wave equation is essentially the same as the Schrödinger equation. It is the wave equation if you look at the spatial part it looks same as the Schrödinger equation for particle in a box. And you can get the solutions in exactly this way ok.

So, the general solutions if we write; so let us just write. So, we will write the general solution $u(x, y, t)$ is equal to So, you have $a_0 \cos(\lambda_1 x) + a_1 \sin(\lambda_1 x)$, $b_0 \cos(\lambda_2 y) + b_1 \sin(\lambda_2 y)$. This is the x part multiplied by y part and multiplied by a time part; the time part is we just call it $d_0 \cos(\lambda t) + d_1 \sin(\lambda t)$. Where $\lambda^2 = \lambda_1^2 + \lambda_2^2$ and $\lambda_1 = n \pi / L_x$. If the domain is from if the domain is from 0 to L_x , $\lambda_2 = m \pi / L_y$. Again if the domain is from if the domain is from 0 to L_x $\lambda_2 = n \pi / L_y$. Again if the domain is if these are the domains, if these are not the domains then you have to you have to write you write the solutions in this other form.

So, what we have seen here is that is that the 2 dimensional wave equation is can be solved by the separation of variables, and the 2 dimensional wave equation is actually very familiar to us because when you do the particle in a 1 dimensional box in quantum mechanics, the solutions looks exactly like this. The equation that you get has exactly this form inside the box. And we are used to seeing these solutions.
