Lecture – 13
Particle in a One-dimensional Box: Part III
Expectation Values and
Postulates in Quantum Mechanics

Prof. Mangala Sunder Krishnan
Department of Chemistry
Indian Institute of Technology Madras

Welcome back to the lecture, we continue from what was there in the last lecture on the Heisenberg's uncertainty principle, and I introduced a simple quantity called the average value or the expectation value.
(Refer Slide Time: 00:31)

Media Offline

New Template.HD

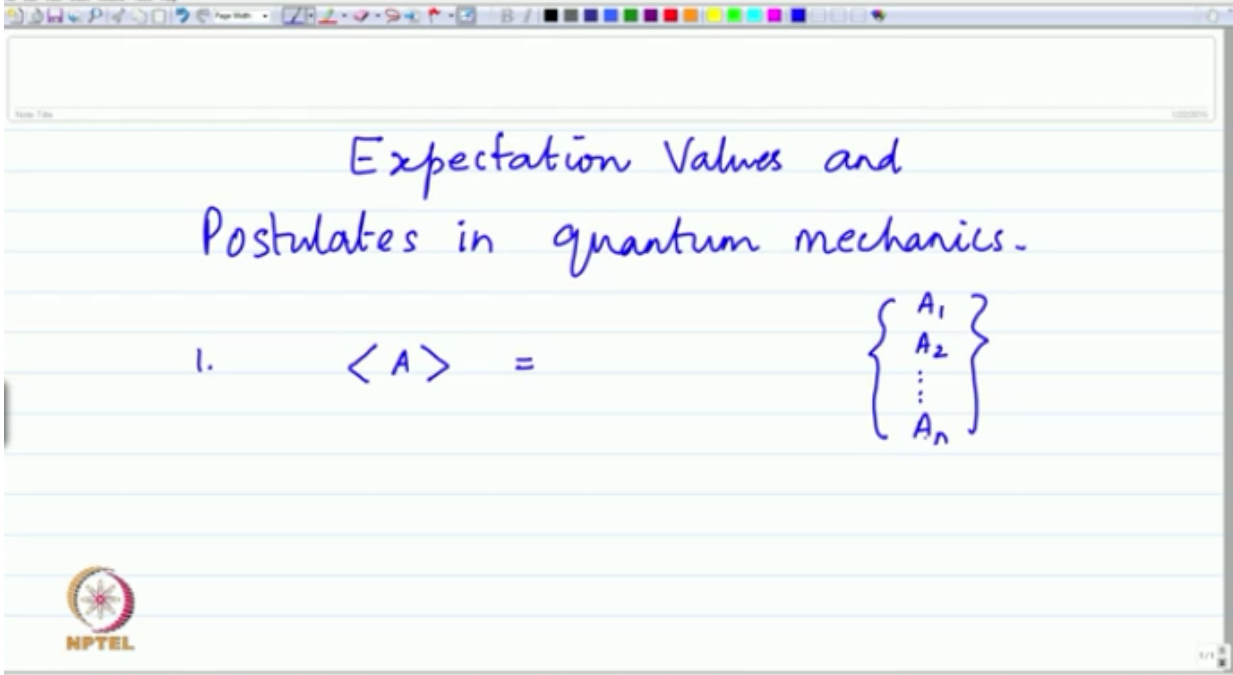

A screenshot of a digital notepad application. The notepad has a white background with light blue horizontal lines. The text "Expectation Values and Postulates in quantum mechanics." is written in a blue, cursive font. The NPTEL logo is visible in the bottom left corner of the notepad window. The window's title bar and toolbar are also visible at the top.

So in this part of the lecture we will consider the formal definition for expectation values in quantum mechanics, and if time permits I shall talk more about the postulatory basis that is basis with which mathematically we can start that, these are the starting points and then quantum mechanics we can build, that's called the postulatory basis, and the postulatory basis in

quantum mechanics will also be stated in very simple terms. The postulates or mathematical in nature, but we will see simple explanations hopefully, okay.

First one is the expectation value, it is denoted by the average value bracket for any quantity, the average value is in general calculated according to the standard prescription that if there are N measurements, and these things happen with different outcomes for the measured quantity A with values A1, A2, AN

(Refer Slide Time: 01:52)

A digital whiteboard interface showing handwritten text in blue ink. The title is "Expectation Values and Postulates in quantum mechanics." Below the title, the first point is written as "1. $\langle A \rangle =$ " followed by a large curly brace containing a vertical list of values: A_1 , A_2 , a vertical ellipsis, and A_n . The whiteboard has a toolbar at the top and an NPTEL logo at the bottom left.

Expectation Values and
Postulates in quantum mechanics.

1. $\langle A \rangle =$ $\left\{ \begin{array}{c} A_1 \\ A_2 \\ \vdots \\ A_n \end{array} \right\}$

NPTEL

for different measurements then you know that the average is nothing but the sum over $I = 1$ to N A_I divided by N .

Now on the other hand suppose you have A_1 occurring N_1 times in an experiment repeated many many times, A_2 occurring N_2 times let me change N_1 , N_2 to something else which is standard, okay P_1 times P_2 times and likewise A_N and these are the only possible values, (Refer Slide Time: 02:37)

Expectation Values and Postulates in quantum mechanics.

1. $\langle A \rangle = \frac{\sum_{i=1}^n A_i}{n}$ $\left\{ \begin{array}{c} A_1 \\ A_2 \\ \vdots \\ A_n \end{array} \right\}$

$A_1 \dots p_1$ times
 $A_2 \dots p_2$ "
 \vdots
 $A_n \dots$

let's see these are the only outcomes that you have occurs PN times, then the average is calculated by adding all the A1,
 (Refer Slide Time: 02:57)

Expectation Values and Postulates in quantum mechanics.

1. $\langle A \rangle = \frac{\sum_{i=1}^n A_i}{n}$ $\left\{ \begin{array}{c} A_1 \\ A_2 \\ \vdots \\ A_n \end{array} \right\}$

$A_1 \dots p_1$ times
 $A_2 \dots p_2$ "
 \vdots
 $A_n \dots p_n$ times

so the average is calculated by adding all the A1, P1 times, and adding A2 which has happened P2 times, and likewise adding all the AN's which have occurred PN times dividing by P1, P2, P3 up to PN okay,
 (Refer Slide Time: 03:40)

$\frac{\sum A_i}{n}$

$\left(\begin{matrix} \vdots \\ A_n \end{matrix} \right)$

$A_1 \dots p_1 \text{ times}$
 $A_2 \dots p_2 \text{ "}$
 \vdots
 $A_n \dots p_n \text{ times}$

$$\langle A \rangle = \frac{(A_1 + A_1 + \dots) + (A_2 + \dots + A_2) + \dots + (A_n + \dots + A_n)}{p_1 + p_2 + p_3 + \dots + p_n}$$

this is also the standard way in which you can calculate the averages if some values repeat many times then you want to find out how many times that it is repeated, what's the probability that that value is repeated and so on.

Now the same thing can now be written by writing $A_1 \times P_1/P$, okay where P is the sum of all of the experiments P_i and therefore P_1/P gives you the probability that you got A_1 for the measurement of A and likewise $A_2 \times P_2/P$ which is the probability that you have the outcome A_2 and so on, therefore you have $A_n \times P_n/P$ okay, so this is a probability (Refer Slide Time: 04:50)

$A_n \dots p_n \text{ times}$

$$\langle A \rangle = \frac{(A_1 + A_1 + \dots) + (A_2 + \dots + A_2) + \dots + (A_n + \dots + A_n)}{p_1 + p_2 + p_3 + \dots + p_n}$$

$$= A_1 \times \left(\frac{p_1}{P} \right) + A_2 \times \left(\frac{p_2}{P} \right) + \dots + A_n \times \left(\frac{p_n}{P} \right) \quad P = \sum_i p_i$$

within brackets that a given value occurs and then what's the average when you do this experiment many many times, this is standard way of representing probabilities and in quantum mechanics. you remember $\psi^* \psi$ represents the probability density for the system at a given coordinate or at a given moment on the variable X in particle in a 1 dimensional box you talk about the $\psi^* \psi dx$ as the probability that the system is in the space between X and X + DX.

And in two dimensions $\psi^* \psi dx dy$ talks about the probability that the system is in the area DX DY which is enclosed between X and X + DX and Y and Y + DY that's what it is, and therefore $\psi^* \psi$ is a sort of a probability and then what you have is the measured value whatever that you measure, you measure the energy or you measure the position you measure the momentum does not matter some experimentally observable quantity for which the reason operator associated with that in quantum mechanics, the measured value gives you the value with that probability and then the average value is the sum of all of those things, the measured value times the probability that it happens summed over all such possible measured values, therefore technically if you are looking at A as a function of X, because please remember this is a continuous function, therefore A is defined for each and every value of X, so what you think is it's like $\psi^* \psi$ which is the probability times the value AX that happens with the X DX provided $\psi^* \psi$ represents the probability density which means this integral $\int \psi^* \psi dx$ should be equal to 1, okay, should be equal to 1, (Refer Slide Time: 07:01)

$$\langle A \rangle = \frac{(A_1 \rightarrow A_1 + \dots) p_1 + (A_2 + \dots + A_2) p_2 + \dots + (A_n + \dots + A_n) p_n}{p_1 + p_2 + p_3 + \dots + p_n}$$

$$= A_1 \times \left(\frac{p_1}{P} \right) + A_2 \times \left(\frac{p_2}{P} \right) + \dots + A_n \left(\frac{p_n}{P} \right) \quad P = \sum_i p_i$$

$$\psi^* \psi \rightarrow \langle A(x) \rangle = \int \psi^* \psi A_x dx$$

$$\int \psi^* \psi dx = 1$$

so if you represent this by probability density in quantum mechanics the average value A is the probability times the value that happens with that probability summed over but with one small technical difference namely that the operator corresponding to A acting on ψ giving you the measured value, and therefore the measured value times the $\psi^* \psi$ is represented by this quantity divided by integral $\int \psi^* \psi dx$, which of course is set to 1 if we think of $\psi^* \psi$ as the probability, so this is the formal definition for the expectation value and this A is the

operator associated with the measured quantity, the physical property called A, this is the physical property.

And this quantity is the mathematical representation or a quantum mechanical representation, quantum mechanical representation of that physical property, okay, you already know because the case of momentum for example the operator associated with P is $-\hbar \frac{d}{dx}$ for one dimension, and what is the operator for the position? It is just the X itself.

What's the operator for the energy? You have already seen that it is the Hamiltonian operator or C operator associated with angular momentum it's a vector and has 3 components in 3 dimensions or in N components in N dimensions so if you write to that in say 3 dimensions you have 3 components and each one of them is represented by a corresponding operator which is (Refer Slide Time: 09:06)

The image shows a whiteboard with handwritten notes. At the top, the average value of a physical property $\langle A \rangle$ is defined as $\frac{\int \psi^* (\hat{A} \psi) dx}{\int \psi^* \psi dx = 1}$. The numerator is labeled 'Formal definition' and the denominator is labeled 'Mathematical (q.m) representation'. Below this, the average value of momentum $\langle p \rangle$ is shown to be represented by the operator $\hat{p} = -i\hbar \frac{d}{dx}$. The average value of position $\langle x \rangle$ is represented by the operator $\hat{x} = x$. The average value of energy E is represented by the operator \hat{H} . The average value of angular momentum $\langle L \rangle$ is represented by the operators L_x, L_y, L_z , with arrows pointing up from each component.

slightly different from the notation that we have here it will be all the derivatives, so the point is every measured quantity has a mathematical representation in quantum mechanics, and the average value that we expect by definition, the average being, the average of an infinitely large number of measurements, the average value that we expect of that system that you see here, (Refer Slide Time: 09:45)

$\langle A \rangle = \frac{\int \psi^* (\hat{A} \psi) dx}{\int \psi^* \psi dx = 1}$

Physical property \uparrow $\langle A \rangle$

Mathematical (q.m) representations \uparrow $\int \psi^* \psi dx = 1$

$\langle p \rangle \Rightarrow \hat{p} = -i\hbar \frac{d}{dx} \quad \hat{E} = \hat{H}$
 $\hat{x} = x \quad \hat{L} \Rightarrow L_x, L_y, L_z$
 $\uparrow \quad \uparrow \quad \uparrow$

NPTEL 3/3

the average value is the $\langle A \rangle$, $\langle A \rangle$ operator \hat{A} dx this is a fundamentally important thing to remember and again when we introduce the postulates of quantum mechanics this will be introduced as one of the postulates of quantum mechanics itself.

Therefore in the last lecture when I said that the average value of the position logically turns out to be somewhere right in the middle of the box for a box of length L you can calculate for one dimension, the average value $\langle x \rangle$ to be $\int x |\psi(x)|^2 dx$ if the state of the system is $\psi(x)$ then the average value in that state is $\langle x \rangle$, the position operator \hat{x} and $\psi(x)$. And $\psi(x)$ being normalized to $1/\sqrt{L}$ whatever you have that is $1/\sqrt{L}$ times $\sin(n\pi x/L)$, you have for the integral 0 to L $\int_0^L \sin(n\pi x/L) x \sin(n\pi x/L) dx$ okay, so this gives you when you do the integral this gives you the answer $L/2$,
 (Refer Slide Time: 11:02)

$$\langle x \rangle_{\psi_n} = \int_0^L \psi_n(x) x \psi_n(x) dx$$

$$= \frac{2}{L} \int_0^L \sin\left(\frac{n\pi x}{L}\right) x \sin\left(\frac{n\pi x}{L}\right) dx = L/2$$

so very simple integral it is $X \sin^2 X$, and the $\sin^2 X$ is of course you can write it as $1 - \cos 2X/2$, and then you do the simple integral on X and $X \cos X$ it's very easy to do.

Likewise the average value for the momentum of the particle was also argued out to be 0 based on the fact that the momentum is a vector and therefore it has a positive or a definite negative direction at any point in space, if you do that the average value of the momentum will turn out to be 0 for the particle in a 1 dimensional box and that's also easy to verify by writing this down as $2/L \sin N \pi X/L$.

Now you remember to put the operator in the middle $\hat{H} \psi = E \psi$ $\frac{d}{dx} \sin N \pi X/L$ times DX , okay, now the derivative of the sine will give you a cosine $N \pi X/L$, you can see mathematically and the sine cosine will give you a $\sin 2N \pi X/L$ times $1/2$, but that integral between 0 to L is a full sine wave and therefore that goes to 0 okay DX ,
(Refer Slide Time: 12:31)

$$\begin{aligned} \langle x \rangle_{\psi_n} &= \int_L \psi_n(x) \hat{x} \psi_n(x) dx \\ &= \frac{2}{L} \int_0^L \sin\left(\frac{n\pi x}{L}\right) x \sin\left(\frac{n\pi x}{L}\right) dx = L/2 \\ \langle p \rangle &= \frac{2}{L} \int_0^L \sin\left(\frac{n\pi x}{L}\right) \left(-i\hbar \frac{d}{dx}\right) \sin\left(\frac{n\pi x}{L}\right) dx \\ &= \cos\left(\frac{n\pi x}{L}\right) \int_0^L \frac{1}{2} \sin\left(\frac{2n\pi x}{L}\right) dx \\ &= 0 \end{aligned}$$

so it's easy to verify simple relations like the expectation values for position, expectation values for momentum and these are the two things that you can think about, and if you have the kinetic energy you already know that the particle in the box is only kinetic energy inside the box, therefore the total energy is the same as that of the kinetic energy and you can see that the average value E for the particle in the state ψ_n is $\frac{\hbar^2 n^2}{8mL^2}$ that also comes out. So these are simple prescriptions for doing calculations for the average values based on quantum mechanics.

(Refer Slide Time: 13:17)

$$\begin{aligned} \langle x \rangle_{\psi_n} &= \int_L \psi_n(x) \hat{x} \psi_n(x) dx \\ &= \frac{2}{L} \int_0^L \sin\left(\frac{n\pi x}{L}\right) x \sin\left(\frac{n\pi x}{L}\right) dx = L/2 \\ \langle p \rangle &= \frac{2}{L} \int_0^L \sin\left(\frac{n\pi x}{L}\right) \left(-i\hbar \frac{d}{dx}\right) \sin\left(\frac{n\pi x}{L}\right) dx \\ &= \cos\left(\frac{n\pi x}{L}\right) \int_0^L \frac{1}{2} \sin\left(\frac{2n\pi x}{L}\right) dx \\ &= 0 \\ \langle E \rangle_{\psi_n} &= \frac{\hbar^2 n^2}{8mL^2} \end{aligned}$$

Now please remember these are average values, expectation values that is these are what are expected when you do many, many measurements, but if I do a single experiment what value will I get? Is there a prescription in quantum mechanics? That's what this equation tells you, okay, if the state of the system is in this function, is in this state ψ_N for the particle in the one dimensional box it doesn't matter, how many times I make measurements on that state for the energy, doesn't matter all the times I will get only one answer namely $E_N = \int \psi_N^* H \psi_N dx$, it's like the simple analogy you have a dye at 6 phases and you print only one dot on all the 6 phases therefore the dye has only one state namely with an outcome of a single dot, no matter how many times you throw the dye, you get only one dot as the answer because that's how you prepared the state of the system, such states are called eigen states in quantum mechanics, okay.

In the case of a dye you have 6 possible things that you have for a single dye 1 dot, 2 dot, 3 dot, 4 dot, 5 dot, and 6 dots, therefore you have 6 possible outcomes. In the case of a particle in the box if I make a measurement and I do not know what the state of the system is, what result can I expect for a single measurement, I've already told you what the result we can expect for a very large number of measurements and then what's the average, that's what we did before what is it for a single measurement if you ask that question the answer is one of the eigenvalues of the system.

In case of the dye which is a normal dye or a regular dye which has 6 different phases with 1, 2, 3, 4, 5, 6 dots there are 6 possible outcomes, multiple outcomes, therefore in a single experiment of throwing the dye we get a dot, or 2 dot or 3 dot all with identical probabilities $1/6$ if the dye is a perfect cube, because the dye is not prepared in any other way.

Likewise in quantum mechanics if the probabilities for all outcomes are uniform, then in a single measurement one of these energies will be the outcome, for the particle in the box if you measure the energy only one of the E_N 's is possible. Which of the E_N ? Statistics, Einstein was very unhappy he said God doesn't play dice, and Niels Bohr told him don't tell god what to do okay, but there is an inherent statistical character built in the measurement outcomes according to what is called the Copenhagen School or the Niels Bohr School of quantum mechanics which is still practiced by most of us, a single measurement will give you one of the eigenvalues and will result in the state of the system being one of that eigen state, the eigen state corresponding to that eigenvalue therefore if we make a measurement for a particle in a one dimensional box in an arbitrary state that we do not know what it is, the result that we will get out is only one result and that result the measurement will give you an eigenvalue E_N and the state of the system will become ψ_N .

This is fundamental in quantum mechanics,
(Refer Slide Time: 17:47)

Average - Expectation expected.

$$H \psi_n = E_n \psi_n$$

$\uparrow \quad \uparrow \quad \quad \uparrow \quad \uparrow$
 energy measurement eigenstates

multiple outcomes.

$$\hat{H} \psi \longrightarrow E_n \psi_n$$

and if the state is already an eigen state then no matter how many times you make copies of that state and how many times you make the measurements you will always get the eigenvalue, that is why I mean I wrote the average value for E in the last slide or the few minutes ago if I go back to the screen I've written that already here, if the state of the system is ψ_n , the measurement of energy every time will give you the same value $H^2 \psi_n^2 / 8ML^2$ square, and since it's the same value in all measurements the average is also the same as the single measurement, if you know the state of the system very precisely that's what it is, if you don't know the state of the system to be an eigen state but an arbitrary ψ , okay, this is the result for an arbitrary ψ , now let me write down the tab ψ here that if the system is in the state ψ a measurement of a quantity, physically will give you $\int \psi^* A \psi dx$ integrated over the domains completely available to the system and for particle in a one dimensional box it's between 0 to L, that's the whole space available to the system therefore you take the average by adding all the probabilities, it's very easy to see that the same one is what you get because if you write $E(\psi_n)$ which is an eigen state of the Hamiltonian operator then you see that this relation is $\int \psi_n^* H \psi_n dx$ and you know between 0 to L, you know that $H \psi_n = E_n \psi_n$, and you know that ψ_n is normalized therefore the answer is $\int_0^L \psi_n^* \psi_n dx$ and with E_n this is equal to 1, and therefore the average value is the same as the eigen value for E_n .

(Refer Slide Time: 20:07)

The image shows a handwritten derivation on lined paper. The first line is $\langle E \rangle_{\psi_n} = \int_0^L \psi_n \hat{H} \psi_n dx$. A wavy underline is drawn under $\hat{H} \psi_n$, and a second line below it shows $E_n \psi_n$ with an arrow pointing from the wavy underline to it. The second line of the derivation is $= \left(\int_0^L \psi_n \psi_n dx \right) E_n = E_n$. A horizontal line is drawn under the integral term, with $= 1$ written below it. In the bottom left corner of the paper, there is a circular logo with a star-like pattern and the text 'NPTEL' below it.

$$\langle E \rangle_{\psi_n} = \int_0^L \psi_n \hat{H} \psi_n dx$$

$$= \left(\int_0^L \psi_n \psi_n dx \right) E_n = E_n$$

Let me stop here and we will continue these discussions over the next few weeks on various aspects, but it's important for us to remember that the expectation value is a fundamentally important quantity, and the fact that involves the wave function and its complex conjugate is a very meaningful reason, it's a very important reason why one is always interested in solving the Schrodinger equation to get the wave function first, that the wave function has an interpretation due to probability is one thing but the wave function is extremely important in the actual calculation for the expectation values and the measurements, and therefore you have a function which you cannot physically explain or visualize but it's very important and very useful for calculating average values as calculating other quantities called matrix elements, calculating the average values through various processes and so on, therefore the wave function has come to stay with all of us. We'll continue this in the next lecture, thank you.
