Lecture – 22
Problems and Solutions for Harmonic Oscillator

Welcome to the lectures in chemistry on the topic of Atomic Structure and Chemical Bonding. My name is Mangala Sunder; I am a professor in the department of chemistry in the Indian Institute of Technology in Madras Chennai.

(Refer Slide Time: 00:31)

And my email ids are given in the screen here for you to contact. This is a video tutorial help for the lecture on simple harmonic oscillator which you have already seen.

(Refer Slide Time: 00:41)

And there are a few simple problems and I would solve these problems and these problems also illustrate elementary methods in calculating and also understanding the basic principles ok.

So, following the practice we have been doing sequenced here, you will see the problems and then I will give you indicate the solutions to each one of them. So, this is on harmonic oscillator.

Chemistry: Atomic Structure and Chemical Bonding
Video Tutorial with Problems and Solutions on
Harmonic Oscillator

Data:

- Planck's constant $h = 6.626 \times 10^{-34} \text{ J.s}$
- Speed of light in vacuum $c = 2.9979 \times 10^8 \text{ m.s}^{-1}$.
- One atomic mass unit (amu) $= 1.66 \times 10^{-27} \text{ kg}$.

Remember the data that you have to keep in mind and you also have to use this the Planck's constant speed of light and the atomic mass unit are the three important fundamental constants we will need for this lecture.

Chemistry: Atomic Structure and Chemical Bonding
Video Tutorial with Problems and Solutions on
Harmonic Oscillator

Problem 1

The molecule CO has vibrational frequency in the harmonic mode as 2140 cm^{-1} .

- What is the force constant for the molecule?
- Determine the energy of transition in Joules per molecule.

So, the first problem is using the harmonic oscillator model and approximating the molecular vibration as a simple harmonic motion. That is possible at low temperatures and also at moderate temperatures when the molecular vibrational states are such that most molecules are in the ground vibrational state. And we can model the vibrational energies and the vibrational wave functions using harmonic oscillator model ok.

Now, assuming that the model is valid, the question is the following the molecule carbon monoxide has a vibrational frequency in the harmonic mode as 2140 centimeter inverse. It is a safe frequency, but you know it is a wave number unit that we are giving. Question is what is the force constant for the molecule and the second question is on the determination of the energy of transition in joules per molecule ok?

(Refer Slide Time: 02:37)

So, value given is problem 1. So, the CO molecule it is important because we need to know the mass of the molecule. The CO molecule the vibrational frequency is given as 2140 centimeter inverse. And we are asked to calculate the force constant for the molecule.

So, the force constant k is related to the frequency ν which is connected with the wave numbers through the relation the speed of light multiplied by the wave number and this is what you have here. The frequency ν is given by this formula 1 by 2π into square root of k by μ or m the mass. Here in carbon monoxide as a vibrating molecule the harmonic oscillator, we cannot use the total energy. But we have to use the reduced mass m is the carbon atomic mass unit 12, oxygen is 16 atomic mass unit and the total is 28.

And of course, you have the conversion 10 raise to minus 27 kilograms ok; this is the mass that we have to make use of. The other thing that you have to remember is that the ν bar is given in centimeter inverse. But SI units for joules and others will involve meter inverse. So, this problem is also about using the units carefully.

(Refer Slide Time: 04:23)

$$C\bar{\nu} = \frac{1}{2\pi} \sqrt{\frac{k}{m}} ; \quad \bar{\nu} = \frac{1}{2\pi C} \sqrt{\frac{k}{m}}$$

$$k = \frac{4\pi^2 \bar{\nu}^2 \times m}{C^2} \quad \text{Units are important}$$

$$= \frac{4\pi^2 \times (2.9979 \times 10^8 \text{ m s}^{-1})^2 \times (2140 \text{ cm}^{-1} \times \frac{100 \text{ m}}{1 \text{ cm}})^{-2}}{28} \times \frac{12 \times 16}{1} \times 1.66 \times 10^{-27} \text{ kg}$$

So, if I write $C\bar{\nu}$ as $\frac{1}{2\pi} \sqrt{\frac{k}{m}}$ then $\bar{\nu}$ is $\frac{1}{2\pi C} \sqrt{\frac{k}{m}}$. And therefore, k is $4\pi^2 \bar{\nu}^2 \times m$. Units are important ok. C is in meters per second $\bar{\nu}$ is in meter inverse and m is in kilograms ok.

So, these are the only things that you need to do. Therefore, let me just put the numbers in and leave it to you to get the answer the numbers that we have are $4\pi^2$ square into 2.9979 into 10 raise to 8 meters per second whole square. And $\bar{\nu}$ square is 2140 centimeter inverse into 100 per meter inverse centimeter inverse. So, this goes away and that is $\bar{\nu}$ square into the mass that we calculated namely the 20 12 into 16 divided by 28 into 1.66 into 10 raise to minus 27 kilograms ok. So, this is pure big and numerical exercise.

(Refer Slide Time: 06:18)

Handwritten notes on a digital whiteboard:

$$\sim 1849.6 \text{ N m}^{-1}$$

1 b) $\Delta E_{(n+1 \rightarrow n)} = h\nu$ Energy of transitions

$$h \times \frac{1}{2\pi} \sqrt{\frac{k}{m}} \checkmark$$

$$= h c \bar{\nu}$$

$$(6.627 \times 10^{-34}) \text{ J s} \times 2.9979 \times 10^8 \text{ m s}^{-1} \times (2140 \times 100) \text{ m}^{-1}$$

Calculate

And I will leave it to you to calculate I think what I calculated the number to be is somewhere around 1849.6 Newton meter inverse Newtons per meter ok. This is the solution to the force constant in problem 1 ok. In the same problem it is also asking you to calculate the energy of transition in joules per molecule. If you recall the harmonic oscillator this is b, delta E is between any level n plus 1 to n. There are no transitions between levels which are separated by more than 1 level.

Therefore, this delta is h nu, this is the energy of transition, because you remember that the harmonic oscillator energy levels are equally spaced and they are half h nu 3 half h nu 5 half h nu and so on. Therefore, the gap between any successive pairs of levels is h nu and you already have calculated the force constant. Therefore, it is h times 1 by 2 pi into square root of k by m the you can use that or you can also use straightforward this number h into C nu bar, which is already given to you as 2140 centimeter inverse. Therefore, the answer is 6.627 into 10 raise to minus 34 joule seconds into 2.9979 into 10 raised to 8 meters per second 2140 into 100 per meter. And you can see that the answer will turn out to be the second goes away and the meter goes away. And therefore, what is left over is the joules and therefore, you can get this answer that calculated. So, this is a very straightforward problem ok.

INDIAN INSTITUTE OF TECHNOLOGY
BOMBAY

The second problem is a little more involved, the second problem uses the wave function for a harmonic oscillator ground state. Which is given here in the screen and you are asked to calculate the range of x for which the probability of locating the particle in the range is 0.9.

Recall that if 1 takes the square of the wave function and plots it as a function of x the area under the entire graph is the total probability of finding the particle in any of that region from minus infinity to plus infinity. And that area is 1 ok, because the wave function is normalized. Therefore, the square of the wave function $d x \psi^2 d x$ between the limits will give you 1. Now you have to find that area for which the probability is 0.9 ok.

(Refer Slide Time: 09:29)

Problem 2, since the ground state wave function is given psi squared if you plot as a function of x is going to be like that and the entire area from minus infinity to plus infinity the area under the graph is 1.

But you have to find that value of x this is minus some c this is plus c that the area here this is 0.9 ok. Psi square is given to you already as psi square x is alpha by pi 1 by 2 e to the minus alpha x squared and psi square x d x is that. Therefore, you have to calculate the area from minus c to plus c minus c to plus c such that the answer is 0.9. one of the reasons for giving this number is that this cannot be calculated analytically.

(Refer Slide Time: 10:50)

You need to know there is no analytical result; you need to use numerical tables. There is analytical result only for this integral minus infinity to plus infinity e to the minus alpha x square by dx or 0 to infinity e to the minus alpha x square dx .

If you have to calculate to this from say minus 0 to some constant c e to the minus alpha x square, this function is actually known as the error function ok. Therefore, the calculation for these numbers for these integrals has to be done numerically and there are numerical tables available ok. So, let us just quickly convert it in a form that they can get this area for the numerical value.

(Refer Slide Time: 11:44)

The image shows a handwritten derivation of the integral for the harmonic oscillator wave function. The derivation is as follows:

$$\int_{-c}^c \psi^2(x) dx = \left(\frac{\alpha}{\pi}\right)^{1/2} \int_{-c}^c e^{-\alpha x^2} dx \quad \alpha = \sqrt{\frac{k_m}{\hbar^2}}$$

Then, a substitution is made:

$$x = \frac{x'}{\sqrt{\alpha}} \quad \alpha x^2 = x'^2 \quad dx = \frac{dx'}{\sqrt{\alpha}}$$

The limits of integration are transformed:

$$x = -c \text{ to } c \Rightarrow x' = -\sqrt{\alpha}c \text{ to } \sqrt{\alpha}c$$

The integral is then rewritten in terms of x' :

$$\frac{1}{\sqrt{\pi}} \int_{-\sqrt{\alpha}c}^{\sqrt{\alpha}c} e^{-x'^2} dx' = \frac{2}{\sqrt{\pi}} \int_0^{\sqrt{\alpha}c} e^{-x'^2} dx'$$

The final result is given as:

$$C \sqrt{\alpha} \cdot (0.792 \text{ to } 0.797)$$

So, what we have is the following namely, the integral psi square x d x between minus and minus c to plus c is alpha by pi to the one half integral minus c to plus c e to the minus alpha x square d x. They are called as the wave function x d x and alpha is already known to you as square root of k by square root of k m by h bar square ok, these are the harmonic oscillator parameters.

So, what you have is this to calculate this integral do you a very simple transformation to say x prime such that it is x prime over root alpha. So, that alpha x squared becomes x prime square and d x is d x prime by root alpha. Therefore, the integral and also the limit x is equal to minus c to plus c implies x prime is equal to minus root alpha c to plus root alpha c.

And then you have you are set namely that the integral this integral transforms to the following minus c to plus c 1 by root pi e there is a root alpha here ,there is a root alpha here, e to the minus x square d x it is x prime square d x prime, but it does not matter. And so, the answer is its root 2 by root pi between 0 to c e to the minus d x prime this is the error function integral.

And if you locate from the tables numerical tables I mean you can look up to the tables from the internet or from any of the text books, which give you error function integrals. The value for this c root alpha for this is c root alpha; the value c root alpha is between 0.792-0.797 ok. Therefore, c is 1 by this number divided by the root alpha.

Alpha is dependent on the molecular system and or the actual problem because, the force constant and the mass are dependent on the model problem that you choose. Therefore, this is the formula that you have to use to calculate the probabilities on any finite value, any finite number and the probability being 1 means it covers the entire area ok. Now, the second part of this question is calculate the maximum value of x permitted for the oscillator using classical limit.

(Refer Slide Time: 15:01)

This is an interesting question; recall that the potential energy for the harmonic oscillator that we use is a parabolic configuration something like the half $k x$ square symmetric ok. Now, this is half $k x$ square as a function of x plus or minus x . The maximum value for the potential, maximum x please remember if you take harmonic oscillator the energy to be some value E .

The extremes for the classical these two extremes which are called the turning points, mark the point or the points at which the oscillator velocity is 0 ok. The harmonic oscillator oscillates swings between the two ends like a you know recall the pendulum and at either ends the velocity is 0 and there the potential energy is the maximum and that is the energy of the oscillator.

Therefore, if the oscillator has a higher energy its things faster to a larger amplitude it is picking up somewhere at the top here instead of. So, if you pick up any energy E the classical value $x_{\max}$ is when E is all potential energy half $k x_{\max}$ whole square no

kinetic energy. This is classical therefore, the point is this point $x_{\max}$ and at the ground state E is half $h \nu$ ok.

(Refer Slide Time: 16:47)

The image shows a handwritten derivation on a whiteboard. At the top, the energy E is equated to two expressions: $E = \frac{1}{2} h \nu = \frac{1}{2} h \frac{1}{2\pi} \sqrt{\frac{k}{m}}$ and $E = \frac{1}{2} k x_{\max}^2$. An arrow points from the first expression to the text "energy of the oscillator". Below this, the equation $x_{\max} = \left(\frac{1}{k} \frac{h}{2\pi} \sqrt{\frac{k}{m}} \right)^{1/2}$ is written. This is then simplified to $x_{\max} = \left(\frac{h^2}{4\pi^2 k m} \right)^{1/4} = \frac{1}{\alpha}$, where α is defined as $\alpha = \left(\frac{4\pi^2 k m}{h^2} \right)^{1/4}$.

And the $E = \frac{1}{2} h \nu = \frac{1}{2} h \frac{1}{2\pi} \sqrt{\frac{k}{m}}$ that is half $h \nu$ and that is equal to $\frac{1}{2} k x_{\max}^2$. This is what is meant by the entire energy of the oscillator quantum mechanical in the limit of this oscillator behaving classically if all its energy is potential energy this is the maximum value of x .

But we know that this is not true, this is only an analogy because a quantum mechanical oscillator has all the x values from minus infinity to plus infinity you are aware of tunneling and so on. Therefore, here we are simply looking after the limited this I mean application assuming that there is a classical system equivalent to that what is the $x_{\max}$ $x_{\max}$ value is then you know what the $x_{\max}$ is this is given by the half goes away.

So, you have $h \nu = \frac{1}{2\pi} \sqrt{\frac{k}{m}}$ into $\frac{1}{k}$ ok. And the whole thing square root and if we simplify this, this is $\frac{h^2}{4\pi^2 k m}$ what this is? This is nothing, but $\frac{1}{\alpha^4}$. Third problem calculate the probability of locating the oscillator in the classically forbidden region. Which is if you go back to the previous graph here, the probability of the oscillator being in the forbidden region is all these values supposing the wave function has for the ground state. It has the square of the wave function has the same ok.

Then what you see is all values of x beyond the $x_{\max}$, which is this region which is this region ok. They are symmetric therefore, you have if you calculate either this or this and then you say to twice that. This is the probability that the oscillator is in the forbidden region this is what is called to the tunneling probability and it is a straightforward answer to write because, once you know what the $x_{\max}$ is.

(Refer Slide Time: 19:39)

The image shows a handwritten equation on a digital whiteboard. The text 'Probability outside of $x_{\max}$ ' is written at the top. Below it, the equation is written as:

$$= \left(\frac{\alpha}{\pi}\right)^{1/2} \int_{-\infty}^{-x_{\max}} e^{-\alpha x^2} dx + \left(\frac{\alpha}{\pi}\right)^{1/2} \int_{x_{\max}}^{\infty} e^{-\alpha x^2} dx$$

The equation is underlined. The whiteboard interface includes a toolbar at the top with various drawing tools and a Windows taskbar at the bottom.

The probability outside of $x_{\max}$ is the integral minus infinity to $x_{\max}$ α by π to 1 by 2 e to the minus αx square dx plus $x_{\max}$ to plus infinity e to the minus αx square dx α by π 1 by 2 ok. This is the probability that the system is outside the classically for is indeed classically forbidden region or outside the parabolic potential region, this is what is meant by the question.

Chemistry: Atomic Structure and Chemical Bonding
Video Tutorial with Problems and Solutions on
Harmonic Oscillator

Problem 3
Determine the Hermite polynomial of order 5
(quantum number $n=5$) using the recurrence relation
between different polynomials,

$$H_{n+1}(y) = 2yH_n(y) - 2nH_{n-1}(y).$$

The first two polynomials are

$$H_0(y) = 1; \quad H_1(y) = 2y.$$

So, the next question is on calculating the harmonic oscillator Hermite polynomials, which are the polynomials as part of the wave functions to different orders, say order 5. And order 5 essentially means quantum number n equal to 5. There is a formal recurrence relation between the Hermite polynomials I think I mentioned this in the lecture.

And the recurrence relation is given by the index n the Hermite polynomial index n plus 1 and n minus 1 and the relations between them the Hermite polynomial with the index n plus 1 is connected to the Hermite polynomial that the index n and n minus 1 by this.

And to use this of course, you need to know n minus 1 and again for some value of y n namely n minus 1 equal to 0 and then n obviously, is 1. So, you have H_0 is given H_1 is given therefore, what is H_{n+1} so, first we will copy this relation.

(Refer Slide Time: 21:47)

$$H_{n+1} = 2yH_n - 2nH_{n-1}$$

$$H_0 = 1, \quad H_1 = 2y$$

$$n=1 \quad H_2 = 2yH_1 - 2H_0 = 4y^2 - 2$$

$$n=2 \quad H_3 = 2yH_2 - 4H_1 = 2y(4y^2 - 2) - 4(2y)$$

$$= 8y^3 - 12y$$

It is $2yH_n - 2nH_{n-1}$ and that is equal to H_{n+1} ok. So, H_0 is 1, H_1 is $2y$. Therefore what is H_2 equal to? H_2 is equal to $2yH_1 - 2H_0$ which is $4y^2 - 2$. What is H_3 ? H_3 is again n equal to 2.

Therefore, $2y$ into H_2 minus n is 2 therefore, it is $4y^2 - 2$ is since given to this is H_1 and the answer is $2y$ into H_2 is $4y^2 - 2$ minus 4 into $2y$. So, the answer is $8y^3 - 12y$. So, now, it is very easy to calculate the rest of it in a similar way and I will give you the answers.

(Refer Slide Time: 23:14)

$$n=2 \quad H_3 = 2yH_2 - 4H_1 = 2y(4y^2 - 2) - 4(2y)$$

$$= 8y^3 - 12y$$

$$H_2 \text{ and } H_3 \text{ and } n=3 \rightarrow H_4(y) = 16y^4 - 48y^2 + 12$$

$$H_5(y) \quad (n=4) = 32y^5 - 160y^3 + 120y$$

Use H_2 and H_3 and the n equal to 3 to get the answer H_4 of y is equal to $16y^4 - 48y^2 + 12$. And likewise H_5 of y using H_4 and H_3 and n equal to 4 to get the answer $32y^5 - 160y^3 + 120y$. So, these are all the various Hermite polynomials of orders as per the quantum number n . So, this is H_5 and then you have this is H_4 and then you have H_3 and so on ok.

So, this recurring recurrence relation gives you how to calculate they have been polynomials of higher order from that of the lower order. So, this is just an exercise to understand that these relations the origin of these relations if you have to you must be in a position to solve our my differential equation which is not yet part of this lecture series.

(Refer Slide Time: 24:36)

Chemistry: Atomic Structure and Chemical Bonding
Video Tutorial with Problems and Solutions on
Harmonic Oscillator

Problem 4

The generating function for obtaining Hermite polynomial is given by the formula

$$H_n(y) = (-1)^n e^{y^2} \frac{d^n}{dy^n} e^{-y^2}.$$

Obtain the first four Hermite polynomials.

Problem number 4, there is another way of calculating the Hermite polynomial using what is known as a generating function. And the generating function now, involves the differentials and you can see the polynomial generating function for the Hermite polynomial is given by this formula from mathematics of the Hermite equation H_n of y is minus 1 raise to n exponential y square and the derivative n th derivative of exponential minus y square.

And using this obtain, the first three or four Hermite polynomial it says four Hermite polynomials. But again its simply application of the differential the derivative to the exponential minus y square ok. So, let us see that quickly for one or two of them ok, it is minus 1 raise to n let us copy this formula.

(Refer Slide Time: 25:36)

The image shows a screenshot of a presentation software window with a pink title bar. The main content area contains handwritten mathematical formulas for Hermite polynomials. The first formula is $H_n(y) = (-1)^n e^{y^2} \frac{d^n}{dy^n} e^{-y^2}$. Below it, the second formula is $H_0(y) = 1$. The third formula shows the derivation for $H_1(y)$: $H_1(y) = (-1)^1 e^{y^2} \frac{d}{dy} e^{-y^2} = (-1) e^{y^2} (-2y) e^{-y^2} = 2y$. The window includes a standard toolbar at the top and a taskbar at the bottom with various application icons.

$$H_n(y) = (-1)^n e^{y^2} \frac{d^n}{dy^n} e^{-y^2}$$

$$H_0(y) = 1$$

$$H_1(y) = (-1)^1 e^{y^2} \frac{d}{dy} e^{-y^2} = (-1) e^{y^2} (-2y) e^{-y^2} = 2y$$

H_n of y is minus 1 raised to the n e to the y squared the derivative n th derivative d/dy to the n th of e to the minus y square. So, H_0 it is easy because, the n is 0. Therefore, this whole thing is one the derivative and the exponential y square and minus y square cancel out therefore, you get the simple answer it is 1.

What about H_1 of y ? H_1 of y is minus 1 e to the y square d/dy of e to the minus y square and that you know immediately the answer is it is minus 1 e to the y squared into minus 2 y e to the minus y square. They cancel off so you get the answer 2 y that you are already familiar with.

(Refer Slide Time: 26:38)

$$\frac{d}{dy} e^{-y^2} = -2ye^{-y^2}$$

$$H_2(y) = (-1)^2 e^{y^2} \left(\frac{d^2}{dy^2} e^{-y^2} \right) = (-1)^2 e^{y^2} \frac{d}{dy} [-2ye^{-y^2}]$$

$$= e^{y^2} [-2e^{-y^2} + 4y^2 e^{-y^2}] = 4y^2 - 2$$

$$\frac{d^2}{dy^2} e^{-y^2} = [(4y^2 - 2)e^{-y^2}]$$

Now, remember the d by d y of e to the minus y square is minus 2 y e to the minus y square to calculate H 2 of y you will need this because, it is minus 1 square e to the plus y square. And its d square by d y square of e to the minus y square, which I would write as minus 1 square e to the y square d by d y of the previous result namely minus 2 y e to the minus y square ok.

Keep this in mind and then the answers will come out immediately because, this is minus 1 squared is plus 1 e to the y square and this is the derivative is minus 2 e to the minus y square and then there is another minus 2 y when you differentiate the exponential. So, this becomes 4 y square e to the minus y square. And obviously, this goes away with that and the answer you get is 4 y squared minus 2.

But what is important is, remember d by d y d square by d y square of e to the minus y square is 4 y square minus 2 e to the minus y square. And use this to calculate to the third order Hermite polynomial d q by d y q e to the minus y square as d by d y of everything that you have here. So, it is important to keep this order in mind and therefore, the rest of it is easy that you can calculate H 3 of y and plus 4 Hermite polynomials mean only that.

So, this is again an algebraic exercise to calculate Hermite polynomials using a generating function.

(Refer Slide Time: 28:34)

Chemistry: Atomic Structure and Chemical Bonding
Video Tutorial with Problems and Solutions on
Harmonic Oscillator

Problem 5

Calculate the average values for potential energy and kinetic energy for the ground state of the harmonic oscillator.

$$\psi(x) = \left(\frac{\alpha}{\pi}\right)^{1/4} e^{-\alpha x^2/2}, \quad \alpha = \sqrt{\frac{km}{\hbar^2}}$$

Next problem, this is an extremely important problem fundamental, calculate the average values for the potential energy and kinetic energy for the ground state of the harmonic oscillator. You need to know the exponential formulas for doing this. And it is also important that we can only calculate the average values, and not the exact eigenvalues of the potential energy and kinetic energy for the harmonic oscillator in quantum mechanics because, the operator for the potential energy and the operator for the kinetic energy do not commute.

And therefore, it is not possible for you to have the eigen functions for both these operators which do not commute. And this is exactly the same thing as saying that the position and the momentum operators do not commute. Therefore, position and momentum cannot have simultaneously exact eigenvalues same process.

It is not necessary that we should always have exact eigenvalues we will have only those operators which commute among themselves. And therefore, the state of the system will always be specified by only those sets of operators, which commute among themselves and those are the properties. Here potential energy and kinetic energy are not properties. In fact, position is not a property; momentum is not a property with respect to the total energy.

If you specify the harmonic oscillator to be precisely in an eigen state, you can only calculate the average value for the position which turns out to be right in the middle there

the harmonic oscillator do not say it is a maximum ok. Now for position momenta they are all only average values that you can calculate. So, let us do that here for the oscillator this problem 5.

(Refer Slide Time: 30:29)

The image shows a handwritten derivation for the average kinetic energy $\langle KE \rangle$ of a harmonic oscillator in its ground state. The derivation is written on a whiteboard with a pink border. It starts with the formula for the expectation value of kinetic energy: $\langle KE \rangle = \int_{-\infty}^{\infty} \psi^* \left(-\frac{\hbar^2}{2m} \frac{d^2}{dx^2} \right) \psi dx$. The ground state wavefunction ψ is given as $\left(\frac{\alpha}{\pi} \right)^{1/2} e^{-\alpha x^2/2}$. The derivation then shows the first derivative of the wavefunction: $\frac{d}{dx} \left[-\alpha x e^{-\alpha x^2/2} \right] = -\alpha e^{-\alpha x^2/2} + \alpha^2 x^2 e^{-\alpha x^2/2}$. The final result is $\langle KE \rangle = \frac{\hbar^2 \alpha}{4m}$.

$$\begin{aligned} \text{Problem 5} \quad \langle KE \rangle &= \int_{-\infty}^{\infty} \psi^* \left(-\frac{\hbar^2}{2m} \frac{d^2}{dx^2} \right) \psi dx \\ &= \left(\frac{\alpha}{\pi} \right)^{1/2} \left(-\frac{\hbar^2}{2m} \right) \int_{-\infty}^{\infty} e^{-\alpha x^2/2} \left[\frac{d^2}{dx^2} e^{-\alpha x^2/2} \right] dx \\ &\quad \frac{d}{dx} \left[-\alpha x e^{-\alpha x^2/2} \right] \\ &\quad \alpha^2 x^2 e^{-\alpha x^2/2} - \alpha e^{-\alpha x^2/2} \end{aligned}$$

Average value for the kinetic energy yes, psi star, a kinetic energy operated is minus H bar square by 2 m d square by d x square psi d x. Here of course, this is minus infinity to plus infinity so the answer is the expression is alpha by pi to 1 by 2.

And you have the minus H bar square by 2 m and the integral minus infinity to plus infinity e to the minus alpha x square by 2 the derivative of d square by d x square e to the minus alpha x square by 2 times d x ok. Now, it is easy to calculate these derivatives the first derivative is of course, minus 2 alpha x divided by 2.

So, you get only the minus alpha x e to the minus alpha x square by 2. And the second derivative is minus so it will give you alpha square x square e to the minus alpha x square by 2 and the other 1 is minus alpha e to the minus alpha x square by 2 ok.

(Refer Slide Time: 32:17)

The image shows a handwritten derivation for the average kinetic energy $\langle KE \rangle$ of a harmonic oscillator. The derivation is as follows:

$$\langle KE \rangle = \left(\frac{\alpha}{\pi} \right)^{1/2} \left(-\frac{\hbar^2}{2m} \right) \left[\alpha^2 \int_{-\infty}^{\infty} x^2 e^{-\alpha x^2} dx - \alpha \int_{-\infty}^{\infty} e^{-\alpha x^2} dx \right]$$

$$\int_{-\infty}^{\infty} x^2 e^{-\alpha x^2} dx = \frac{1}{2\alpha} \sqrt{\frac{\pi}{\alpha}} \quad \int_{-\infty}^{\infty} e^{-\alpha x^2} dx = \sqrt{\frac{\pi}{\alpha}}$$

$$\langle KE \rangle = \left(\frac{\alpha}{\pi} \right)^{1/2} \left(-\frac{\hbar^2}{2m} \right) \left[\frac{\alpha}{2} \sqrt{\frac{\pi}{\alpha}} - \alpha \sqrt{\frac{\pi}{\alpha}} \right] = \frac{\hbar^2}{4m} \alpha$$

Finally, the value of α is given as:

$$\alpha = \sqrt{\frac{km}{\hbar^2}}$$

So, this is the derivative and therefore, the kinetic energy average value of the kinetic energy is α by π 1 by 2 into minus $\hbar$ bar square by $2m$. And then you have two integrals to calculate namely, α square integral minus infinity to plus infinity x square e to the minus αx square dx . And then you have another 1 minus integral minus infinity to plus infinity αe to the minus αx square dx ok.

So, the integral x square e to the minus αx square dx this is standard integral the formula is 1 by 2 α into root over α ok. And the integral e to the minus αx square by 2 dx the αx square dx in minus infinity this is root π over α ok.

Therefore, the kinetic energy is calculated as follows namely, it is α by π 1 by 2 minus $\hbar$ cross square by $2m$ into α square divided by this. Therefore, α by 2 root π over α and the other is minus α root π to over α ok. So, this is minus 1 by 2 α root π over α and that cancels off that the minus sign what you have is $\hbar$ bar square by $4m$ into α . And α is square root of km by $\hbar$ bar square.

(Refer Slide Time: 34:40)

The image shows a handwritten derivation on a digital notepad. The first equation calculates the expectation value of kinetic energy, $\langle KE \rangle$, as $\frac{\hbar^2}{4m} \sqrt{\frac{km}{\hbar^2}} = \frac{\hbar}{4} \sqrt{\frac{k}{m}} = \frac{\hbar \nu}{4}$. The second equation states the total energy $E = \frac{1}{2} \hbar \nu$. The third equation calculates the expectation value of potential energy, $\langle PE \rangle = \langle \frac{1}{2} k x^2 \rangle$, using the ground state wavefunction $\left(\frac{\alpha}{\pi}\right)^{1/2} \int_{-\infty}^{\infty} e^{-\alpha x^2} \frac{1}{2} k x^2 dx$. The final line shows the integral simplified to $= \frac{1}{2} k \left(\frac{\alpha}{\pi}\right)^{1/2} \int_{-\infty}^{\infty} e^{-\alpha x^2} dx$.

Therefore to simplify the average value of kinetic energy is $\hbar$ bar square by 4 m into square root 4 m into k m by $\hbar$ bar square it gives you $\hbar$ bar 1 $\hbar$ bar goes away and then km if you do this becomes by 4 square root of k.

And this is of course, you know $\hbar$ bar is $\hbar$ by 2 pi and 1 by 2 pi of this is k, but this 1 is nu. Therefore, this is $\hbar$ nu by 4 this is the average value. And remember the energy for the harmonic oscillator, which is an eigen function for the sum of the kinetic energy operator and the potential energy operator the energy is half $\hbar$ nu for the ground state.

And so, what you see here, is the kinetic energy is exactly half of this the average value not the kinetic energy at any given instant of time that you cannot calculate the average turns out to be $\hbar$ nu. It is easy now to see the potential energy in a similar way the potential energy average is obviously; the average of half k x square and that is again the integral is alpha by pi to 1 by 2 e to the minus alpha x square.

Now, we do not need to put these things in between so, we can write this as 1 by 2 k x square dx between the limits minus infinity and plus infinity. So, what you have is 1 by 2 k alpha by pi 1 by 2 the integral e to the minus alpha x square dx.

(Refer Slide Time: 36:40)

The image shows a handwritten derivation on a digital notepad. The first part calculates the expectation value of potential energy $\langle PE \rangle$ as $\langle \frac{1}{2} kx^2 \rangle$. It then shows the integral $\int_{-\infty}^{\infty} e^{-\alpha x^2} dx$ and its value $\frac{\sqrt{\pi}}{\sqrt{\alpha}}$. The second part simplifies the expression to $\langle PE \rangle = \frac{1}{2} k \times \frac{1}{2\alpha} = \frac{1}{4} k \times \sqrt{\frac{\hbar^2}{km}} = \frac{\hbar}{4} \sqrt{\frac{k}{m}}$, which is then equated to $\frac{\hbar \nu}{4}$. The final result is $\langle PE \rangle = \langle KE \rangle$.

$$\begin{aligned} \langle PE \rangle &= \langle \frac{1}{2} kx^2 \rangle = \left(\frac{\alpha}{\pi} \right) \int_{-\infty}^{\infty} e^{-\alpha x^2} x^2 dx \\ &= \frac{1}{2} k \left(\frac{\alpha}{\pi} \right)^{1/2} \int_{-\infty}^{\infty} e^{-\alpha x^2} x^2 dx \\ &= \frac{1}{2} k \left(\frac{\alpha}{\pi} \right)^{1/2} \frac{\sqrt{\pi}}{2\alpha} \\ \langle PE \rangle &= \frac{1}{2} k \times \frac{1}{2\alpha} = \frac{1}{4} k \times \sqrt{\frac{\hbar^2}{km}} = \frac{\hbar}{4} \sqrt{\frac{k}{m}} \\ &= \frac{\hbar \nu}{4} \\ \langle PE \rangle &= \langle KE \rangle \end{aligned}$$

And this value you know already that this is α and also there is dx^2 here. So, this integral is $1/\sqrt{2\alpha}$ times $\sqrt{\pi}$. So, the answer is for the potential energy. If you substitute that it's $1/\sqrt{2\alpha}$ times $\sqrt{\pi}$, this way you have $1/\sqrt{2\alpha}$ which is $1/\sqrt{2k}$ times $\sqrt{\pi}$. $1/\sqrt{2k}$ is obviously, $\hbar^2/km$ and that is given as $\hbar^2/4km$.

And so, that is also $\hbar\nu/4$ because $\hbar/2\pi$ times 4 and $1/2\pi$ times that is 4 . So, the average value of the potential energy for the ground state is equal to the average value for mean kinetic energy also partly known state.

This is an extremely important and interesting result that you have to and they both are equal to half the energy of the harmonic oscillator the total energy of the harmonic oscillator.

Problem 6

Verify the Heisenberg's uncertainty relation for the ground state of the harmonic oscillator.

$$\psi(x) = \left(\frac{\alpha}{\pi}\right)^{1/4} e^{-\alpha x^2/2}, \quad \alpha = \sqrt{\frac{km}{\hbar^2}}$$

$$\Delta x \Delta p \geq \frac{\hbar}{2}$$

NPTEL

Next problem, verify the Heisenberg's uncertainty relation for the ground state of the harmonic oscillator. I have actually done all the elements of integration that you need for calculating this quantity. And therefore, I will indicate to you and you would find out that in this case the delta x delta p is exactly equal to h bar by 2.

And the ground state of the harmonic oscillator is also known as the minimum uncertainty state for the harmonic oscillator. You will just quickly see that result and the calculations can be done by you as I have already done that in this tutorial that is right.

(Refer Slide Time: 38:36)

6. Heisenberg's uncertainty relation

$$\Delta x \Delta p = \sqrt{[\langle x^2 \rangle - \langle x \rangle^2]} \sqrt{[\langle p^2 \rangle - \langle p \rangle^2]}$$

$$\psi: \langle x \rangle_{av} = \left(\frac{\alpha}{\pi}\right)^{1/4} \int_{-\infty}^{\infty} e^{-\alpha x^2/2} x dx = 0$$

odd function

$$\langle x^2 \rangle_{av} = \left(\frac{\alpha}{\pi}\right)^{1/4} \int_{-\infty}^{\infty} e^{-\alpha x^2/2} x^2 dx \quad \frac{1}{2\alpha} \sqrt{\frac{\pi}{\alpha}}$$

Now, Heisenberg's is this problem I believe 6 yes, problem 6 Heisenberg's uncertainty relation $\Delta x \Delta p$ is square root of x^2 minus x average square multiplying p^2 average minus p average square.

Now, for the harmonic oscillator ψ the x average is α by $\pi^{1/2} e^{-\alpha^2 x^2/2}$ between minus infinity to plus infinity you know that this is an odd function. And it is between symmetric intervals and for this answer is 0 and x^2 average if you have to do that that is again α by $\pi^{1/2}$ from minus infinity to plus infinity you have $e^{-\alpha^2 x^2/2}$. This integral I have already told you is $\pi^{1/2} \alpha$.

(Refer Slide Time: 40:12)

$$\checkmark \langle x^2 \rangle_\psi = \frac{1}{2\alpha} \quad \alpha = \sqrt{\frac{km}{\hbar^2}}$$

$$\langle p^2 \rangle = -\hbar^2 \frac{d^2}{dx^2} \quad \langle KE \rangle = \left\langle -\frac{\hbar^2}{2m} \frac{d^2}{dx^2} \right\rangle = \frac{\hbar \nu}{4}$$

$$\left\langle -\frac{\hbar^2}{2m} \frac{d^2}{dx^2} \right\rangle = \frac{m \hbar \nu}{2}$$

$$\langle p \rangle = 0 \Rightarrow \left(\frac{\alpha}{\pi} \right)^{1/2} \int_{-\infty}^{\infty} e^{-\alpha x^2/2} \left(-i\hbar \frac{d}{dx} \right) e^{-\alpha x^2/2} dx = 0$$

even odd even

Therefore the x^2 average for this ground state is $\pi^{1/2} \alpha$ and this α by $\pi^{1/2}$ will go away this is $\pi^{1/2} \alpha$ ok. And you know α is square root of km by $\hbar^2$. So, this is known p^2 average please remember, p^2 is minus $\hbar^2$ d^2 by dx^2 . And we just calculated that the average value of the kinetic energy which is the average value of the operator minus $\hbar^2$ by $2m$ d^2 by dx^2 is $\hbar \nu$ by 4 ok.

Therefore you can immediately see that the p^2 average is minus $\hbar^2$ d^2 by dx^2 should be $2m$ times this therefore, you have $2m \hbar \nu$ by 4 which is $m \hbar \nu$ by 2 this is the p^2 average. What is a p average? It is also easy to see that this is 0 because, the p average is you put the operator between the $e^{-\alpha^2 x^2/2}$ and the minus α

x square the wave function. And you have minus i h bar d by d x acting on the e to the minus alpha x square by 2 d x.

You know this will change the even function to an odd function and the product of this or this is even this is odd this is even. And therefore, the product will be odd and the answer is 0. Therefore, you have p square average is 0 a sorry p average is 0 you have p square average is given by the 2 and you have x square average is given x average is 0.

(Refer Slide Time: 42:25)

The image shows a handwritten derivation in a software application window titled 'Notes - Windows Journal'. The derivation calculates the uncertainty product $\Delta x \Delta p$ for a harmonic oscillator ground state. It starts with the general formula $\Delta x \Delta p = \sqrt{\frac{\hbar \nu m}{2} \times \frac{1}{2\alpha}}$. Then, it defines $\nu = \frac{1}{2\pi} \sqrt{\frac{k}{m}}$ and $\alpha = \sqrt{\frac{k^2}{\hbar m}}$. Substituting these into the formula gives $\frac{\nu}{\alpha} = \frac{1}{2\pi} \sqrt{\frac{k \hbar^2}{\hbar m m}} = \frac{\hbar}{2\pi m}$. Finally, the uncertainty product is calculated as $\Delta x \Delta p = \sqrt{\frac{\hbar}{4} \times \frac{\hbar}{2\pi m}} = \frac{\hbar}{2}$.

$$\Delta x \Delta p = \sqrt{\frac{\hbar \nu m}{2} \times \frac{1}{2\alpha}}$$

$$\nu = \frac{1}{2\pi} \sqrt{\frac{k}{m}} \quad \alpha = \sqrt{\frac{k^2}{\hbar m}}$$

$$\frac{\nu}{\alpha} = \frac{1}{2\pi} \sqrt{\frac{k \hbar^2}{\hbar m m}} = \frac{\hbar}{2\pi m}$$

$$\Delta x \Delta p = \sqrt{\frac{\hbar}{4} \times \frac{\hbar}{2\pi m}} = \frac{\hbar}{2}$$

Therefore it is very easy to calculate the delta x delta p as square root of h nu by 2 m m by 2 into the other answer x square average is 1 by 2 alpha 1 by 2 alpha ok.

Now, all you know is that substitute all these things, nu is 1 by 2 pi square root of k by m and 1 by alpha is square root of h bar square by k m. Therefore, nu by alpha is going to give you 1 by 2 pi square root of k h bar square by k m m k goes away. And so you have 1 by 2 pi m h bar and there is already an m here.

Therefore, you can calculate this is only nu by alpha therefore; delta x delta p is square root of h m by 4. And the nu by alpha is obviously, h bar by 2 pi m and h by this is 2 pi h by 2 pi is h bar m goes away. And therefore, you have h bar square by 4 and the answer is h bar by 2.

You see that the delta x delta p is exactly h bar by 2 this is called the minimum uncertainty state. And it is an extremely important harmonic oscillator ground state obeys

the Heisenberg's uncertainty principle to it is limit. It is not a higher uncertainty, is not a lower uncertainty it is the minimum given by Heisenberg's formula that is important.

Problem 7

For a classical harmonic oscillator, identify precise values for kinetic energy and potential energy for all possible values of x if the total energy is E_{total} . Are such precise values permissible in quantum mechanics? Explain your answer.

Now, the next problem is the problem of some concept for a classical harmonic oscillator, identify the size values for kinetic energy and potential energy for all possible values of x . If the total energy is E_{total} , that is a fairly straightforward thing from the parabola that we can calculate, but then the question is are such precise values permissible in quantum mechanics explain your answer. And the answer is of course, no such precise values are not permissible in quantum mechanics so, let us see what these classical values are in the first place.

(Refer Slide Time: 45:26)

For a classical oscillator the potential energy as a parabola is something that you have to remember ok. This is the potential energy as a parabola is something that you have to remember ok. This is the $\frac{1}{2} kx^2$ and this is x positive x to the negative minus infinity and the parabolic curve is something like that ok; it is the symmetrical oh myself.

So, if we have an E_{total} which is given by some value E_{total} . Then you remember this value of x_{max} which is the turning point for the classical oscillator, where the kinetic energy is 0 gives you the maximum value for the potential energy. So, at this point the potential energy is half $k x_{\text{max}}^2$ ok, this is x_{max} this is minus x_{max} kinetic energy is 0 ok. So, this is item one and that corresponds to this point.

Now, let us take any point in between let us take this point let us take this point, so, let me use a different color ok. Let us take this point and the corresponding point here ok. The potential energy is given by half $k x_{\text{value}}^2$, which is the x_{value} here ok, some $x_{\text{intermediate}}$ i. So, the total energy still of course, this because that is the E_{total} .

Therefore, if this is the potential energy quite, obviously, this is the kinetic energy potential energy, but remember for a classical oscillator every point of the harmonic oscillator the parabolic curve is well defined because, we know the graph the point as well as its velocity at that point the steepness we know. Therefore, classically we know the position and the momentum of the particle very very clearly at each and every instant of time therefore; we can say that the oscillator goes around like this.

And at each such point, we know that the kinetic energy is the difference between the total energy and the maximum potential energy bounded by the graph this point ok. So, if you have to do any other point again, if you have to take this then you know that this is the kinetic energy and the corresponding value this is the potential energy. So, it is very precisely defined for each and every x max, why it cannot be done in the case of quantum mechanics for this.

First of all this parabolic curve for a quantum mechanic system is not a very meaningful thing. Because the harmonic oscillator can have any value of x classically forbidden value it does not mean that the kinetic energy is negative. The kinetic energy or the potential energy as individual attributes or individual measurement quantities are not available you only can measure the total energy.

(Refer Slide Time: 49:16)

$$H = \underbrace{-\frac{\hbar^2}{2m} \frac{d^2}{dx^2}}_{KE} + \underbrace{\frac{1}{2} kx^2}_{PE}$$

$$\begin{aligned} [KE_{op}, H] &\neq 0 \\ [PE_{op}, H] &\neq 0 \end{aligned} \quad \begin{array}{l} KE, PE \text{ are not} \\ \text{eigenvalues simultaneously} \end{array}$$

$$A\psi = a\psi \quad [A, B] = 0 \quad B\psi = b\psi$$

Therefore the quantum mechanical result says very clearly that the Hamiltonian, when it is written with minus $\hbar^2$ by $2m$ is square by $d x$ square plus half $k x$ square. Remember operator for the kinetic energy is this is the operator for the potential energy the kinetic energy operator does not commute with the overall Hamiltonian. Because it may commute with itself, but this operator does not commute with the x square term.

And likewise, the potential energy operator does not commute with the H go to 0 is not 0. Because $k x$ square will commute with the k square part of the Hamiltonian, but $k x$ square will not commute this. Therefore, KE PE are not again values simultaneously.

So, what is important for you is to remember that, when two operators A and B, when they commute $A\psi = a\psi$ and $B\psi = b\psi$ can have an eigenvalue a and an eigenvalue b, same eigen function different eigenvalues are possible.

(Refer Slide Time: 50:43)

However, if the operators do not commute then it is not possible for you to define the same state such that A of ψ is given by the eigen value equation and B of ψ is given by another eigenvalue equation.

This is not permissible and therefore, the definition of potential energy and harmonic oscillator kinetic energy at each and every instant of the position is not simultaneously definable for a quantum oscillator.

Harmonic Oscillator

Problem 8

Determine the values of x for which the probability density is/are maximum (maxima). Assume that the harmonic oscillator is in the first excited state (quantum number = 1), given by

$$\left(\frac{4\alpha^3}{\pi}\right)^{1/4} x e^{-\alpha x^2/2}$$

Determine the values of x for which the probability density is or maximum, I mean if there is more than one maximum, then you have to calculate all of them. And one example of a function given is the harmonic oscillator in the first excited state given by this formula that $4\alpha^3/\pi$ by π to the power of $1/4$ times x times e to the minus $\alpha x^2/2$ ok. Actually the numerical constant is not relevant for the problem, but anyway we will keep that. What we are asked to do is to so, for calculating the maximum or minimum in the probability.

(Refer Slide Time: 51:55)

$\psi^2 \quad \psi \sim x e^{-\alpha x^2/2}$

$\Rightarrow \frac{d|\psi|^2}{dx} = 0$

Value of x

$\frac{d^2\psi}{dx^2} \geq 0 \rightarrow \text{minimum}$

$\frac{d^2\psi}{dx^2} < 0 \rightarrow \text{maximum}$

$\psi^2 \Rightarrow x^2 e^{-\alpha x^2}$

$\frac{d\psi^2}{dx} = 2x e^{-\alpha x^2} - 2\alpha x^3 e^{-\alpha x^2} = 0$

We need psi square and psi is given as $x e^{-\alpha x^2}$. Therefore, we have to take the derivative of the psi square with respect to x that should be set to 0. And the second derivative $d^2 \psi$ by $d^2 x$ for the value of x at which this derivative is 0, if the second derivative is greater than or equal to 0 this is a minimum. This value of x this value of x is a minimum. If $d^2 \psi$ by $d^2 x$ is less than 0, the value of x for which the psi square is your maximum.

So, what we will do is, let us calculate $x^2 e^{-\alpha x^2}$ which is $x^2 e^{-\alpha x^2}$ roughly, we do not need to worry about the constants. It is $x^2 e^{-\alpha x^2}$. Therefore, $d \psi^2$ by $d x$ is equal to $2 x e^{-\alpha x^2} - 2 \alpha x^3 e^{-\alpha x^2}$ that should be 0.

(Refer Slide Time: 53:35)

And you know that the exponential level goes to 0. Therefore, it is $2x - 2\alpha x^3 e^{-\alpha x^2}$. If this is 0, this should be 0, or $x(1 - \alpha x^2) = 0$, x is equal to plus or minus $1/\sqrt{\alpha}$. So, if you recall the probability you also have one more result namely, x is equal to 0. So, there are three values of x for which the derivative is 0, three values of x x is equal to 0, x is equal to plus $1/\sqrt{\alpha}$, x is equal to minus $1/\sqrt{\alpha}$.

So, now we have to find out which is maximum and which is minimum. Of course, one quick way to do that is to plot the function $x^2 e^{-\alpha x^2}$ this is ψ^2 and this is psi square. And you know the psi square actually goes to 0 at x is

equal to 0. And you see that the function is $x^2 e^{-\alpha x^2}$ and at x is equal to 0 this is 1, but this is 0.

But for all other values of x at least in the beginning x^2 increases and this decreases therefore, the function has a shape like that ok. And since it is in the properties this is an even function. It has a shape like that they are the same. If you want to look at they are symmetric anyway well as near me as you can. Now you would see right away that x is equal to 0 seems to be a minimum, this is the value and also this is $1/\sqrt{\alpha}$ and this is $1/\sqrt{\alpha}$ where, the function is a maximum and the derivative here is 0, the derivative here is 0.

(Refer Slide Time: 56:16)

The image shows a digital whiteboard with handwritten mathematical work. At the top, the first derivative is given as $\frac{d}{dx} x^2 e^{-\alpha x^2} = [2x - 2\alpha x^3] e^{-\alpha x^2}$. Below this, the second derivative is calculated using the product rule: $\Rightarrow (2 - 6\alpha x^2) e^{-\alpha x^2} - 2\alpha x (2x - 2\alpha x^3) e^{-\alpha x^2}$. The work then evaluates the second derivative at $x=0$, showing it is greater than 0, which indicates a minimum. Finally, it states that $x = \pm 1/\sqrt{\alpha}$ are the maxima. At the bottom, a simple sketch of a bell-shaped curve is drawn, representing the function $f(x)$.

$$\frac{d}{dx} x^2 e^{-\alpha x^2} = [2x - 2\alpha x^3] e^{-\alpha x^2}$$

$$\Rightarrow (2 - 6\alpha x^2) e^{-\alpha x^2} - 2\alpha x (2x - 2\alpha x^3) e^{-\alpha x^2}$$

$$x=0 \quad > 0$$

minimum.

$$x = \pm \frac{1}{\sqrt{\alpha}} \text{ are the maxima.}$$

The other way is to look at calculate d^2 by $d x^2$ on $x^2 e^{-\alpha x^2}$ to the minus αx^2 . And since you know that it is already d by $d x^2$ minus $2\alpha x^3 e^{-\alpha x^2}$ to the minus αx^2 . So, this will be $2 - 6\alpha x^2$ times $e^{-\alpha x^2}$ that is one term. And the second term is $-2\alpha x (2x - 2\alpha x^3) e^{-\alpha x^2}$.

Therefore, if you put x is equal to 0, you can see immediately that this goes to 0 this is 2, this whole term is 0. Therefore, this is greater than the derivative is greater than 0, second derivative. Therefore, this is a minimum this is what you saw in the graph ok. Now, if you put x is equal to $1/\sqrt{\alpha}$ you can see that this is x^2 is 1 by

alpha and this is alpha cancels out this is 2 minus 6. And then you have x is equal to 1 by root alpha and if you do that the whole thing will turn out to be negative ok.

Whether you put plus alpha or minus alpha 1 by root alpha plus or minus 1 by alpha both will give you the second derivative to be less than 0. So, x is equal to plus or minus 1 by root alpha or the maxima for this function. I think that is what this problem is all about. The idea behind these problems that is being discussed in detail is that some of the mathematics, which you might find in your first attempt to do this.

If you find them difficult that is some help here, but ideally I would like you to do the mathematics yourself and then come back and check on the way it is being done. And if there are any mistakes, which have been made in the lecture please let me know and I shall correct the corresponding video lecture and we will replace it with the corrected one. We will continue with the lectures.

And until then thank you very much.
