**First Law of Thermodynamics**

(Refer Slide Time: 0:17)

Okay, so welcome to the next lecture so we have introduced the first law of thermodynamics the other day right? So now we are going to move ahead with more formulations of thermodynamics.

(Refer Slide Time: 0:32)

A presentation slide with a white background and a dark header. The title 'First Law of Thermodynamics' is centered at the top, underlined. Below the title, there are three bullet points, each starting with a red arrow. The first bullet point is the equation  $\Delta U = q + w$ . The second bullet point is the equation  $dU = dq + dw$  with the text '(First Law of Thermodynamics)' in blue. The third bullet point is a paragraph explaining that the first law is a postulate and that  $dU$  is not dependent on the path. At the bottom of the slide, there is a footer that reads 'Chemical Principles II -- Arnab Mukherjee'.

So first law of thermodynamics is a combination of like says that change in the internal energy is a combination of both heat and work and for an infinitesimal change we can write

as  $dU$  equal to  $dq$  plus  $dw$ . Now we already mentioned that the first law is a postulate that states that the property  $U$  is a function of state variables that can be changed either two ways and also it is independent of path, right it is not dependent on path.

What it means will become clear today, but remember that we are saying that as a postulate taking that to be a state function and also we know that it is law of conservation of energy and because it depends on the state when it comes back whichever path it you know carries on when it comes back to the same point, it will be 0.

(Refer Slide Time: 1:32)

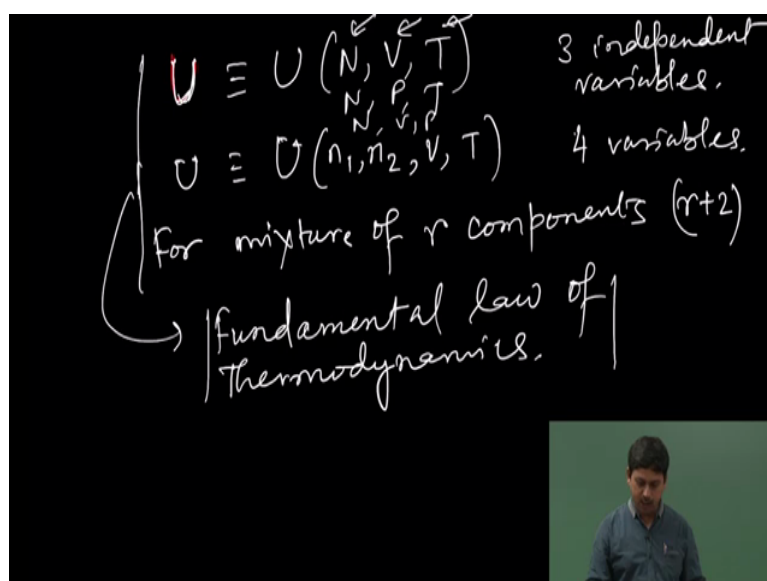

Okay, so now we are going to discuss today about state function and path function, basically what it means is that how a property varies as a function of its own variables that is called state function and path function so it will become more clear today.

(Refer Slide Time: 1:48)

So what are the variables of internal energy?

(Refer Slide Time: 1:56)

So we say that as a postulate that internal energy  $U$  (I will just change that colour) internal energy  $U$  is basically a function of  $N$ ,  $V$  and  $T$ , 3 variables. So by that what it means is that for one component system it will depend on number of moles, volume and temperature. Therefore, for one component system there are 3 independent variables and when it is a let us say multi component mixture or let us say two component system, then internal energy will depend on chemical composition of the first component, chemical composition of the second component, volume and temperature, so in that case 4 variables.

So in general for a mixture of  $r$  variables (how many independent)  $r$  components rather than variables (I will just clarify that)  $r$  components how many independent variables will be there? For 1 component 3, so for  $r$  component will be  $r + 2$  independent variables. So the other variables will be dependent on that, okay. So which means that once you specify the number of moles, volume and temperature or let us say number of moles, pressure and temperature or number of moles, volume and pressure  $U$  can be determined from that, okay.

And that  $U$  will know as fundamental law of thermodynamics, we will come back to that later again after we cover second law and all, we will come back to this fundamental law of thermodynamics later. But right now we will just introduce it, because we now actually so we are mapping the variables like  $N$ ,  $P$  and  $T$  into a value of  $U$ , it is like a function functional form, only thing that we do not know what is the nature of the function? How nature of the function means how can we express  $U$  in terms of  $N$ ,  $V$  and  $T$  that is not known, that will vary from system to system.

However, we can say that for 1 component system these are the variables on which we will depend on and it does not matter how we arrive at that value, it does not matter which path we take from coming from one state to that particular state. So we define the state by  $N$ ,  $V$  and  $T$  its independent variables, they define the state just like let us say for example we talk about phase base we define position and momentum and that defines a system, if you define position, movement of all the particles.

Similarly for microscopic variables once we define these independent variables, we define the system all together. Once we know this information we can calculate every property once we have this fundamental law of thermodynamics we can calculate every property from that particular thing, okay. So that is one thing that we wanted to say.

(Refer Slide Time: 5:18)

### Variables of Internal Energy?

- $U \equiv U(N, V, T)$ ,  $U$  depends on 3 variables for one component system
- We can also write it as,  $U \equiv U(N, P, T)$ , or  $U \equiv U(N, P, V)$
- $U \equiv U(n_1, n_2, V, T) \rightarrow U$  depends on 4 variables for binary mixtures

So, in general the description of a homogeneous mixture of  $N$  species require  $N + 2$  variables.

Chemical Principles II -- Arnab Mukherjee

And this we covered that and in yes so that we have covered. So now since it is dependent on multiple variable system, since  $U$  depends on multiple variables we can see that when you change those variables the value will change, the property will change. For example when I change number of moles  $U$  will change or temperature change then  $U$  will change and things like that. So how it changes, depending on change of one variable to another variable can be understood by understanding differentiation.

(Refer Slide Time: 6:04)

### Partial Differentiation

$$y = f(x)$$
$$\frac{dy}{dx} = \lim_{\Delta x \rightarrow 0} \frac{f(x+\Delta x) - f(x)}{\Delta x}$$
$$P = \frac{nRT}{V} \quad \text{--- (1)}$$
$$\left(\frac{\partial P}{\partial T}\right)_{n,V} = \lim_{\Delta T \rightarrow 0} \frac{P(T+\Delta T, n, V) - P(T, n, V)}{\Delta T}$$
$$\left(\frac{\partial P}{\partial T}\right)_{n,V} = \frac{nR}{V}, \quad \left(\frac{\partial P}{\partial V}\right)_{n,T} = \frac{-nRT}{V^2}$$

Chemical Principles II -- Arnab Mukherjee

Now if a function depends on only one variable let us say we call it  $f(x)$  as a function let us say  $y$  equal to  $f(x)$  is a function and we want to know how this particular function changes with respect to  $x$ , then what we say? We do a differentiation  $dy$  by  $dx$ , so what  $dy$  by  $dx$  tells us

from first principle is that as  $x$  tends to 0 how  $f(x)$  changes from  $f(x)$  to  $f(x + \Delta x)$ . So this is the definition from first principle that given a function of one variable how one can get the change of that function with small change of the variable by divided by of course the variable difference. So this is from the first principle the definition of a differentiation.

Now let us talk about pressure for part you know ideal gas system, a pressure can be written as  $nRT/V$ , right. So here you can see that it depends on  $(R)$  it depends on  $n$  because  $R$  is the constant,  $T$  and  $V$  three variables, right. So now let us say if I want to calculate for this that how this particular function changes with respect to temperature, but then there are other two variables that on which it depend on, pressure depends on three variables now  $N$ ,  $T$  and  $V$  and we wanted to see how it changes with respect to just one variable  $T$  and if we do that then we call that as partial differentiation and you see the notation is  $\partial$  instead of  $d$ .

So when you write that  $dP/dT$  we are saying that how  $P$  changes with respect to  $T$  alone keeping  $n$  and  $v$  constant. So how we can write from first principle, you can write  $\lim_{\Delta T \rightarrow 0} \frac{P(T + \Delta T, n, v) - P(T, n, v)}{\Delta T}$ , so this is the definition of partial differentiation, right. So we can give some example, so let us say if I want to calculate  $\partial P / \partial T$  as a function of  $n, v$  for a particle you know from equation 1 let us say then what we are going to get is  $nR/V$ .

Similarly we can calculate  $\partial P / \partial V$  at a constant  $n$  and temperature which will give us  $-nRT/V^2$ . So I assume that you guys know how to do differentiation from 12th standard and this is so in partial differentiation we just take the other variables as constant, nothing else and that will help us to carry out the changes with respect to one particular variable. Okay, so now we are going to see that if let us say more than one variable change, what will happen?

(Refer Slide Time: 9:10)

Partial Differentiation

$$df = \lim_{\Delta y \rightarrow 0} \frac{f(x, y + \Delta y) - f(x, y)}{\Delta y} + \lim_{\Delta x \rightarrow 0} \frac{f(x + \Delta x, y) - f(x, y)}{\Delta x} dx$$

---

Say  $f(x, y)$   
 $f(x, y) \rightarrow f(x + \Delta x, y + \Delta y)$   
 $f(x + \Delta x, y + \Delta y) - f(x, y) = \Delta f$   
 $\Delta f = [f(x + \Delta x, y + \Delta y) - f(x + \Delta x, y)] + [f(x + \Delta x, y) - f(x, y)]$   
 $= \frac{[f(x + \Delta x, y + \Delta y) - f(x + \Delta x, y)] \times \Delta y}{\Delta y} + \frac{[f(x + \Delta x, y) - f(x, y)] \times \Delta x}{\Delta x}$   
 Now let's take  $\Delta x \rightarrow 0$  &  $\Delta y \rightarrow 0$

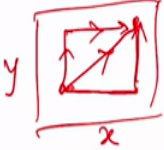

Chemical Principles II -- Arnab Mukherjee

Partial Differentiation

$$df = \lim_{\Delta y \rightarrow 0} \frac{f(x, y + \Delta y) - f(x, y)}{\Delta y} dy + \lim_{\Delta x \rightarrow 0} \frac{f(x + \Delta x, y) - f(x, y)}{\Delta x} dx$$

---

$df = \left(\frac{\partial f}{\partial y}\right)_x dy + \left(\frac{\partial f}{\partial x}\right)_y dx$   
 $df = \sum_i \left(\frac{\partial f}{\partial x_i}\right) dx_i$   
 Total differential.

Chemical Principles II -- Arnab Mukherjee

Okay, so now let us say a function  $f$  a function  $f$  depends on more than one variable  $x$  and  $y$ , okay. So in that case I want to see how the function changes with respect to both the variables, how do I look at, how do I understand that? So we want to see that how  $f(x, y)$  goes to  $f(x + \Delta x, y + \Delta y)$ . So how do I write that? We can say that  $f(x + \Delta x, y + \Delta y) - f(x, y)$  is equal to  $\Delta f$ . So I want to see how the function changes based on the change of both its variables, not just one let us say it depends on only 2, we saw that  $P$  depends on 3 variables, but here we are just taking only 2 of the and then see that how it turns out, how we can write that?

So we say that the amount of the amount of changes in  $f$  is  $\Delta f$  and that change is happening by change of the variables  $x$  and  $y$  both. So we can write the difference here like

that and then we are going to add and subtract this particular quantity so we write  $\Delta f$  as  $f(x + \Delta x, y + \Delta y) - f(x + \Delta x, y) + f(x + \Delta x, y) - f(x, y) + f(x, y) - f(x, y + \Delta y) + f(x, y + \Delta y) - f(x, y)$  and then we are going to add and subtract this quantity  $f(x + \Delta x, y) - f(x, y)$  and add this quantity  $f(x, y + \Delta y) - f(x, y)$  since we are adding and subtracting it does not make any difference it remains the same, correct? Because what we did is that we just added this, subtracted this, added this same quantity two times,  $\Delta f$  remains same.

Now we are going to take put them in a bracket, okay. So within the for the first bracket we are going to multiply and divide by  $\Delta x$ . So  $f(x + \Delta x, y + \Delta y) - f(x + \Delta x, y)$  this one we are going to multiply by  $\Delta x$  and divide by  $\Delta x$ , I am all going by first principle, okay. Second one no first one we are going to do  $y$ , second we are going to do  $x$ ,  $f(x + \Delta x, y + \Delta y) - f(x, y + \Delta y)$  into  $\Delta x$  by  $\Delta x$  so we got two terms.

Okay, so now let us take  $\Delta x$  tends to 0 and  $\Delta y$  tends to 0, what is going to happen? Look at the first term, in the first term if I take the  $\Delta x$  to be 0, then I have  $\Delta x$  in both the cases, okay if I take now I can take the limit right away. So we are taking now limit to  $\Delta y$  and  $\Delta x$  tends to 0 for both of them, okay. So left hand side will become (so actually I do not have space so I should write here then) left hand side will become  $df$  is equal to why I am putting  $df$ ? Because we are taking limit, for them limit  $\Delta x$  tends to 0 and  $\Delta y$  tends to 0.

Now this quantity since we are taking the limit  $\Delta x$  tends to 0, it will be simply 0 and it will also be 0. But here  $\Delta y$  we cannot just take to be 0, because we are dividing by  $\Delta y$  also. So what we are going to have is  $f(x + \Delta x, y + \Delta y) - f(x + \Delta x, y)$  divided by  $\Delta y$  limit  $y$  tends to 0 plus  $f(x + \Delta x, y + \Delta y) - f(x, y + \Delta y)$  divide by  $\Delta x$  into  $\Delta x$ , now you see what is happening so  $df$  becomes now this particular term that we have that particular term is from first principle is nothing but  $\frac{\partial f}{\partial y}$  at a constant  $x$ , right agree? (Oh I forgot to write  $dy$  here  $\Delta y$ ) and  $\Delta y$  becomes  $dy$  because we are taking  $\Delta y$  to be very small and right hand side becomes  $\frac{\partial f}{\partial x}$  at a constant  $y$  because see the  $y$  value remains constant  $dx$ , is it clear?

So basically what we have done is that we have shown that from first principle if a function depends on multiple variables then the change of function can be associated with the change of either of that variables, if it depends on 3 variables, we have to have 3 such terms we apriory do not know whether  $y$  changes or  $x$  changes, but we are saying that if  $y$  or  $x$  change then the overall change in the function will be sum of this partial differentiation with respect to the variable multiplied by the change in variable.

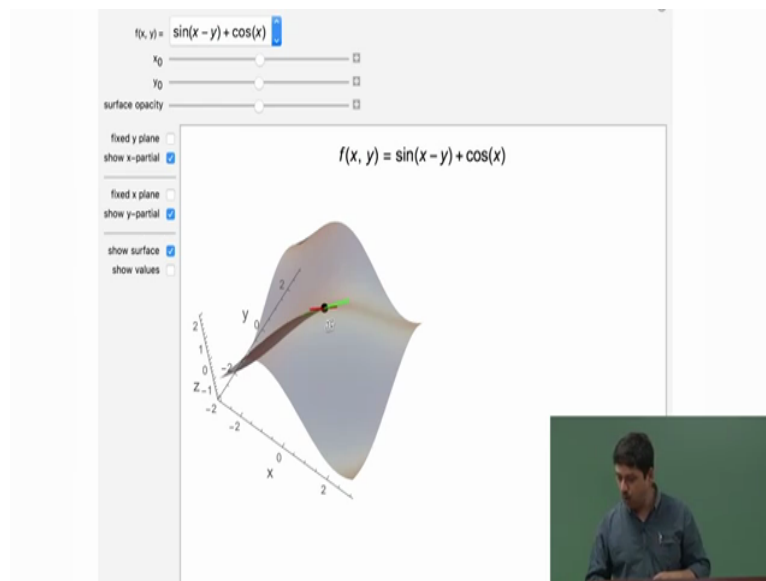

So in principle if quantity depends on many many variables we can write as  $df = \sum_i \frac{\partial f}{\partial x_i} dx_i$  and  $i$  then  $i$  can go to 1 to whatever number of variables it has. So this is what called total differential, it is called total differential that that means how much difference is there all together when we change these variables. Now what does it mean basically? It means that let us say I have a 2 dimensional surface and then I want to reach from this point to that point, now I can go along this one and then along this one, so let us say this is my  $x$  coordinate and this is my  $y$  coordinate.

So I can vary along  $x$  and then along  $y$  or I can vary along  $y$  and then along  $x$  or I can have a combination of both, so by changing the amount of  $x$  or the amount of  $y$  this creates many different paths to reach from one point to another point. If you had only one variable there is only one path to go, but since you have a multiple variables there are multiple paths because all possible combinations  $x, y$  will give you a new path, okay.

So that is what that creates this path functions because now this  $f$  has the possibility to reach different different paths, okay. So imagine that we are talking about a mountain and then let us say one particular place of a mountain has some height. Now that height is independent of path, so height as a function of  $x$  and  $y$  coordinates is independent of path because you can reach whichever way to that particular point you will get the same height, okay so that height is we can call it an exact differential, okay.

Whereas, if you get to a property where if you change that then you will get different different values then will be called I exact differential, okay. Now we will see we will see that later on, but before that I just want to show you how this particular differentiation look like.

(Refer Slide Time: 17:22)

So for example here we are showing a particular function  $f(x, y)$  is  $\sin(x - y) + \cos(x)$  some function is drawn here, okay and this is one particular point here some  $x_0, y_0$  we can vary the point also along  $x_0$ , see along  $x_0$  it has some minima, along  $y_0$  it has some minima, so let us take that point here and then we can show that how the derivative looks like.

So this is some one plane which is fixed along  $x$ , this is a fixed along  $y$  plane and now you see that this is partial derivative along  $y$ , can you observe that? And I can show you partial derivative along  $x$  at that point you see. So at that point for that particular value of  $y_0$  you are looking at how it changes along the  $x$ , that slope is going to give you the partial derivative. So ideally these slopes can be different in different directions.

So but however, here the  $z$  coordinate do you think will be dependent or independent of paths, the  $z$  coordinate will it be dependent on path or independent of path? It will be independent of path, because it is just a function of  $x$  and  $y$ , just like our  $U$  is a function of  $V$  and  $T$  and  $n$  so therefore it is independent of path given a value of  $V$ , given a value of  $T$  it will give you exact value of  $U$  so it is independent of path whenever there is a function of those variables will be independent of path.

(Refer Slide Time: 19:14)

Partial Differentiation

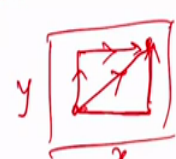

$$df = \lim_{\Delta y \rightarrow 0} \frac{f(x, y + \Delta y) - f(x, y)}{\Delta y} dy + \lim_{\Delta x \rightarrow 0} \frac{f(x + \Delta x, y) - f(x, y)}{\Delta x} dx$$

---

$$df = \left(\frac{\partial f}{\partial y}\right)_x dy + \left(\frac{\partial f}{\partial x}\right)_y dx$$

$$df = \sum_i \left(\frac{\partial f}{\partial x_i}\right) dx_i$$

Total differential.

$$df = M dy + N dx$$

Exact differential,  $\left(\frac{\partial M}{\partial x}\right)_y = \left(\frac{\partial N}{\partial y}\right)_x$

Chemical Principles II -- Arnab Mukherjee

Partial Differentiation

$$df = \lim_{\Delta y \rightarrow 0} \frac{f(x, y + \Delta y) - f(x, y)}{\Delta y} dy + \lim_{\Delta x \rightarrow 0} \frac{f(x + \Delta x, y) - f(x, y)}{\Delta x} dx$$

---

$$\left\{ \frac{\partial}{\partial x} \left[ \left(\frac{\partial f}{\partial y}\right)_x \right] \right\}_y = \left[ \frac{\partial}{\partial y} \left(\frac{\partial f}{\partial x}\right)_y \right]_x$$

$$\rightarrow \frac{\partial^2 f}{\partial x \partial y} = \frac{\partial^2 f}{\partial y \partial x} \Rightarrow \text{Exact differential.}$$

$$\frac{\partial^2 U}{\partial V \partial T} = \frac{\partial^2 U}{\partial T \partial V}$$

$$U = \frac{3}{2} pV$$

$$\frac{\partial U}{\partial T} = 0$$

$$\frac{\partial^2 U}{\partial V \partial T} = 0$$

Chemical Principles II -- Arnab Mukherjee

But now how do you actually show that it is independent of path and what is the formula for doing that? So let us say so now we have written total differential in terms of the partial differential, now we simplify a little bit and we say that  $\partial f / \partial y$ ,  $x$  is  $M$  so we can write  $M dy$  plus  $N dx$ , okay and for exact differential, the criteria is that  $\partial M / \partial x$  so  $M$  came from differentiation with respect to  $y$ , now we have to do with respect to  $x$ ,  $\partial M / \partial x$  with respect to  $y$  is  $\partial N / \partial y$  with respect to  $x$ . So it is exact differential if it satisfies this criteria otherwise it will be an inexact differential.

So you see why we got that, so now you know that  $M$  is already a partial derivative of with respect to  $y$ , now if you combine together it essentially means that  $\partial f / \partial y$  at a constant  $x$  is our  $M$ , right and that one we are taking a derivative with respect to  $x$  at a constant  $y$  is

equal to the opposite thing. So whenever this condition is satisfied we say that it is an exact differential.

So if you look at physically, instead of mathematically what do you observe? You see that first thing that is changing we can simplify this by the way, we can simplify as  $d^2f$  by  $dx dy$  is equal to  $d^2f$  by  $dy dx$ . If this is satisfied then it is an exact differential or a state function, what it physically means? It physically means that you go first along  $y$  for a fixed value of  $x$  here and then you go along  $x$  for a fixed value of  $y$ , first go along  $y$  for a fixed value of  $x$  and then you go along  $x$  for a fixed value of  $y$  on the left hand side.

What the right hand side says? That you go along  $x$  for a fixed value of  $y$ , then go along  $y$  for a fixed value of  $x$ . If you look at the derivative  $dx dy$  and  $dy dx$  they are not same, first we are taking derivative with respect to  $y$  then  $x$  and here first  $x$  and then  $y$ . So it only means that if you do one and then the other it does not matter, if there is an exact differential you will reach the same point, otherwise it will be an inexact differential.

Since we know that  $U$  to be an exact differential we can for  $U$  atleast we can write that  $\frac{\partial^2 U}{\partial V \partial T}$  is equal to  $\frac{\partial^2 U}{\partial T \partial V}$ , okay.  $U$  for an ideal gas you know it is  $\frac{3}{2} PV$ , right. So  $\frac{\partial U}{\partial T}$  is basically going to be 0 and therefore  $\frac{\partial^2 U}{\partial V \partial T}$  is so it is not that interesting a quantity here, okay. So we are going to show some interesting quantity.

(Refer Slide Time: 22:32)

**State Function and Path Function: Exact and Inexact Differential**

State function is an exact differential; Path function is an inexact differential

$z = f(x, y)$ ;  $z$  is a function

$dz = \left(\frac{\partial z}{\partial x}\right)_y dx + \left(\frac{\partial z}{\partial y}\right)_x dy$ ;  $dz$  is a differential

$dz = M(x, y)dx + N(x, y)dy$

$dz$  can be changed by either changing along  $x$  direction or changing along  $y$  direction or both.

If  $\left(\frac{\partial M}{\partial y}\right)_x = \left(\frac{\partial N}{\partial x}\right)_y$  i.e.,  $\left[\frac{\partial}{\partial y} \left(\frac{\partial z}{\partial x}\right)_y\right]_x = \left[\frac{\partial}{\partial x} \left(\frac{\partial z}{\partial y}\right)_x\right]_y$

Then,  $dz$  is an exact differential and a state function. If the above is not satisfied,  $dz$  is an inexact differential and therefore will be a path function

Chemical Principles II -- Arnab Mukherjee

But let me see before that whatever is there. Yes, so this is what we discussed here this is what we discussed.

(Refer Slide Time: 22:42)

$$P = \frac{RT}{v-b} - \frac{a}{v^2} \quad P = P(T, v)$$

$$\left(\frac{\partial P}{\partial T}\right)_v = \frac{R}{v-b} \quad (1)$$

$$\left\{ \frac{\partial}{\partial v} \left[ \left(\frac{\partial P}{\partial T}\right)_v \right] \right\}_T = \frac{-R}{(v-b)^2} \quad (1)$$

$$\left(\frac{\partial P}{\partial v}\right)_T = \frac{-RT}{(v-b)^2} + \frac{2a}{v^3} \rightarrow 0$$

$$\left\{ \frac{\partial}{\partial T} \left(\frac{\partial P}{\partial v}\right)_T \right\}_v = \frac{-R}{(v-b)^2} \quad (2)$$

$$\frac{\partial^2 P}{\partial T \partial v} = \frac{\partial^2 P}{\partial v \partial T}$$

So we are going to just solve for one particular system  $P$  equal to  $\frac{RT}{V \text{ minus } b}$  minus  $\frac{a}{V \text{ bar square}}$ , right. So here  $P$  is a function of  $T$  and  $V$ , right so we can do first with respect to  $T$  at a constant  $V$  what we are going to get  $\frac{R}{V \text{ minus } b}$ , right. Now let us say we do we take the derivative of 1 again with respect to  $V$  now, now  $\frac{\partial}{\partial V}$  of this quantity  $\frac{\partial P}{\partial T}$  now this one has to be at a constant  $T$  is going to be  $-\frac{R}{V \text{ minus } b \text{ square}}$ , right let us call that equation 1.

And (let us do the equation) let us do the other way round, so  $\frac{\partial P}{\partial V}$  at a constant  $T$  is what  $-\frac{RT}{V \text{ minus } b \text{ whole square}} - \frac{2a}{V \text{ cube}}$ , correct, is it correct? Now let us do the second one now it is with respect to  $T$  and at a constant  $V$  so now  $V$  will be constant So since with respect to  $T$  this quantity goes to 0 and this quantity will give you  $-\frac{R}{V \text{ minus } b \text{ whole square}}$ , equation number 2.

Now does it match? 1 and 2 match? Yes, so now we can say that  $d^2P$  by  $dT dV$  is equal to  $d^2P$  by  $dV dT$ , which means  $P$  is an exact differential for the Van der Waal gas that we have discussed, okay.

(Refer Slide Time: 24:44)

$$\begin{aligned}
 P &\equiv P(V, T) \\
 dP &= \left(\frac{\partial P}{\partial T}\right)_V dT + \left(\frac{\partial P}{\partial V}\right)_T dV \\
 &= \left(\frac{R}{V-b}\right) dT + \left[\frac{-RT}{(V-b)^2} + \frac{2a}{V^3}\right] dV \\
 \text{Say, } dP &= \left(\frac{RT}{V-b}\right) dT + \left[\frac{RT}{(V-b)^2} - \frac{a}{TV^2}\right] dV \\
 df &= M dx + N dy \quad \left(\frac{\partial M}{\partial y}\right)_x = \left(\frac{\partial N}{\partial x}\right)_y
 \end{aligned}$$

Since P is a function of V and T, we can write dP as del P del T V dT plus del P del V T dV, right we can write that. Now we have already calculated what those quantities are, what was the del P del T at a constant V? It was R by V minus b dT and the second one was minus RT by V minus b square plus 2a by V cube into dV, okay so this was the derivation. Now this gave us perfectly this gave us the exact differential P as an exact differential.

Now let us say we do not want to write that, we want to express dP in this form let us say RT by V minus b dT plus RT by V minus b whole square minus a by TV square dV. Say this is it is lie this. Now can you tell me that P is an exact differential or not? You remember it is a M dx plus N dy formula, remember? So I will remind you df is here M dx plus N dy, in that case what we have to check del M by so M dx means already there was a derivative with respect to x has happened. So with respect to y we have to do at a constant x and we have to check with respect to x at y, are you following?

(Refer Slide Time: 26:36)

**State Function and Path Function: Exact and Inexact Differential**

State function is an exact differential; Path function is an inexact differential

$z = f(x, y)$ ;  $z$  is a function

$dz = \left(\frac{\partial z}{\partial x}\right)_y dx + \left(\frac{\partial z}{\partial y}\right)_x dy$ ;  $dz$  is a differential

$dz = M(x, y)dx + N(x, y)dy$

$dz$  can be changed by either changing along  $x$  direction or changing along  $y$  direction or both.

If  $\left(\frac{\partial M}{\partial y}\right)_x = \left(\frac{\partial N}{\partial x}\right)_y$  i.e.,  $\left[\frac{\partial}{\partial y}\left(\frac{\partial z}{\partial x}\right)_y\right]_x = \left[\frac{\partial}{\partial x}\left(\frac{\partial z}{\partial y}\right)_x\right]_y$

Then,  $dz$  is an exact differential and a state function. If the above is not true, the  $dz$  will be an inexact differential and therefore will be a path function

Chemical Principles II -- Arnab Mukherjee

We can go back and check that whether it is a case or not  $\frac{\partial M}{\partial y}$  by  $\frac{\partial N}{\partial x}$  see  $M$  came because I already derived with respect to  $x$ , so the next one would be  $y$ , right.

(Refer Slide Time: 26:44)

$$dP = \left(\frac{RT}{V-b}\right) dT + \left[\frac{RT}{(V-b)^2} - \frac{a}{TV^2}\right] dV$$

$$\frac{\partial}{\partial V} \left(\frac{RT}{V-b}\right) = \frac{-RT}{(V-b)^2} \quad \text{--- (1)}$$

$$\frac{\partial}{\partial T} \left[\frac{RT}{(V-b)^2} - \frac{a}{TV^2}\right] = \frac{R}{(V-b)^2} + \frac{a}{TV^2} \quad \text{--- (2)}$$

① ≠ ②

→ Here  $P$  is an inexact differential.  
Inexact differential = ~~State~~ Path

Now if you go back  $dP$  is let us say we say that  $RT$  by  $V$  minus  $b$   $dT$  plus  $RT$  by  $V$  minus  $b$  square minus  $a$  by  $TV$  square, if that is the case that is the case will it be an exact differential? So for that what we have to do is that we have to take this quantity with respect to  $V$   $\frac{\partial}{\partial V}$  of  $RT$  by  $V$  minus  $b$  is going to give us minus  $RT$  by  $V$  minus  $b$  square and this right hand side we have to take with respect to  $T$ , you understand why I am doing that right?

Because since I have already V, I know that I have to do with respect to T, since I have T, I know that I have to do with respect to V it is like 2 variable case only, right. So now if I do the right hand side with respect to that RT by V minus b square minus a by TV square what I am going to get? I am going to get R by V minus b square minus plus minus minus plus T square V square, correct.

Now you see this 1 and 2 are not same so therefore this quantity if dP is expressed by this way then here P is an inexact differential, okay. So now I will say I will tell you that exact differentials differential is equal to state function inexact or (I will write here) inexact differential is a path function, okay.

(Refer Slide Time: 28:58)

### State Function and Path Function: Exact and Inexact Differential

---

State function is an exact differential; Path function is an inexact differential

$z = f(x, y)$ ;  $z$  is a function

$dz = \left(\frac{\partial z}{\partial x}\right)_y dx + \left(\frac{\partial z}{\partial y}\right)_x dy$ ;  $dz$  is a differential

$dz = M(x, y)dx + N(x, y)dy$

$dz$  can be changed by either changing along  $x$  direction or changing along  $y$  direction or both.

If  $\left(\frac{\partial M}{\partial y}\right)_x = \left(\frac{\partial N}{\partial x}\right)_y$  i.e.,  $\left[\frac{\partial}{\partial y}\left(\frac{\partial z}{\partial x}\right)_y\right]_x = \left[\frac{\partial}{\partial x}\left(\frac{\partial z}{\partial y}\right)_x\right]_y$

Then,  $dz$  is an exact differential and a state function. If the above is not satisfied,  $dz$  is an inexact differential and therefore will be a path function

Chemical Principles II -- Arnab Mukherjee

So this is just of the thing, so I will just show you the summary, summary is there in this particular slide, okay.
