Tutorial 4

1) What are the highest order rotational sub-groups of following pt. gps: ?

$$C_{6h} \Rightarrow E, C_6, C_3, C_2, C_6^2, C_6^4, i, S_6^5, S_6^4, \sigma_h, S_6, S_3$$

$$E, C_6, C_6^2, C_6^3, C_6^4, C_6^5$$

$$\{E, C_6, C_3, C_2, C_6^2, C_6^4\} \Rightarrow C_6 \text{ point group}$$

$C_6$  is highest order rot. sub-group of  $C_{6h}$

$$D_{2d} \Rightarrow E, 2S_4, C_2, 2C_2', 2\sigma_d$$

$$E, C_2, C_2', C_2'' \Rightarrow D_2 \text{ point group}$$

$$D_2 \subset D_{2d} \quad \text{where } C =$$

Welcome back so in this week tutorial we will be discussing some of the practical applications of point group. So far what we have learnt. So, let us see some of the kind of questions which try to change the words, so that the question appears very difficult but then what is the approach to solve such kind of questions? So, let us and will try to work out at least 4 questions of different types.

So, let us see the first one is what are the highest order rotational sub-groups of following point groups? So, question is asking that what are the highest order rotational sub-groups? So sub-group as you know is the set of group elements which follow all four properties of that particular of the group out of that particular point group. So, let us say if we have  $C_{6h}$ . So now we should know how to find out what are the symmetry elements or symmetry operations present.

So, let me just list down for  $C_{6h}$ . I have written it here with me. So, you have  $E, C_6, C_3, C_2$  these are all the group elements or symmetry operations  $C_3^2, C_6^5$  each of this is a

different class, then we have  $S_3^5$ ,  $S_6^5$ ,  $\sigma_h$ ,  $S_6$ ,  $S_3$ , so these are the set of elements now it is saying that what is the highest-order rotational sub-group so for rotational sub-group you have to consider the rotational elements on these which is your rotational axis that is  $C_6$ .

So,  $C_6$  is the highest order axis. So, let us see if we generate all the operations from  $C_6$ , do we get a sub-group out of this? So that will be  $E$ ,  $C_6$ ,  $C_6^2$ ,  $C_6^3$ ,  $C_6^4$ ,  $C_6^5$  and  $C_6^6$  will be  $E$ . So now this is equivalent to  $C_6$  then this will be  $C_3$ . So, we have  $C_3$  here. Now this will be  $C_2$ , we have  $C_2$  here, this will be  $C_3^2$ , we have  $C_3^2$ , and this will be  $C_6^5$ . So, these are the elements which contain only rotation pure rotation.

So, we wanted to see if the pure rotation sub-group is present. So yes, our subset is present we do not know whether it is sub-group or not. So, let us see so if we look at just these 6 elements this actually forms a point group for the cyclic group  $C_6$ . So, if we look at  $C_6$  point group, then that is composed of only these elements. So  $E$ ,  $C_6$ ,  $C_3$ ,  $C_2$ ,  $C_3^2$  and  $C_6^5$ . So, we can directly say that yes this is a  $C_6$  is a highest-order rotational sub-group of  $C_6h$ .

So that was easy so you can do the idea is you have to find out only the elements which composed of rotational operations and then see whether it is forming. So, in this case we already know that it is forming a  $C_6$  point group. But ideally you should be testing it for all four group properties that all four group properties like closure associativity, inverse and identity all four are conforming to this set of elements.

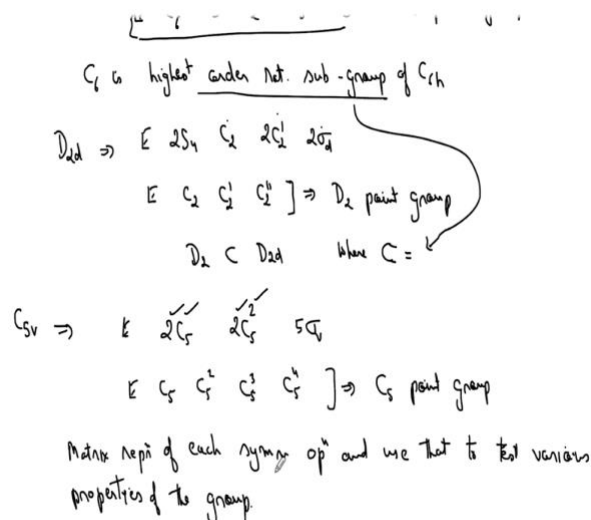

So, then we can say that  $C_6$  is the highest order or rotational sub-group. So similarly let us look at another one. So, we have  $D_{2d}$  here so now what are the elements present or the group of this thing present the  $D_{2d}$  will be symmetry operations will be  $E$ , 2  $S_4$  and we have  $C_2$  and 2  $C_2'$  prime and 2  $\sigma_D$ s. So now we are only interested in the rotational things. So, this is not rotational this is reflection this is rotation and reflection.

We only want the rotation, so the rotational sub-group will be  $E$ ,  $C_2$ ,  $C_2'$  and we can call it a  $C_2$  double prime or we can call it 2  $C_2$ s here. So basically 3  $C_2$ s which are perpendicular to each other that is our subset. Now this subset does it belong to a particular point group or not we

have to identify. So, if we look at yes it does belong to, so the point group is D2 here, let me just also look at the literature yes.

So, if we say that this belongs to D2 point group, and thus you can see this is the highest-order rotational sub-group of D2d. So, D2 is the highest-order rotational sub-group of the D2d. I am just saying D2 is a subset of D2d. So, we have a subset is meaning highest-order rotational sub-group. So, I hope this is clear this is the kind of questions which is sometimes asked in different types of exams.

**(Refer Slide Time: 07:11)**

So, I thought it will be interesting to cover this C5v. So now C5v what are the group elements under C5v? We have E, 2C5. So, 2 operations given by C5, two operations given by C5 square and 5 sigma-Vs. Now what is the highest-order rotational sub-group so we cannot consider this one. So, we have E if you consider the operations generated by C5 now, so this will be C5, C5 square, C5 cube, C5^4 these are the operations that will be generated.

So, all these following any point group, yes so this will be a C5, point group. But do we have all the elements which are present here in this. So now that again we can test by looking at if all of these elements all of these do, they conform to the associativity, closure and all the properties. So individually we have to work it out pick up any example and start working on it or else what you

can also do is when you are testing these properties you can take the matrix representation of each symmetry operation and use that to test various properties of the group.

So, once you do the matrix representation, you do not have to imagine a molecule and do all the operations to find out the property. So, take x, y, z as the basis create a matrix representation for all of this and find out whether if all these are following the properties of the group are not. So, this is one type of questions.

**(Refer Slide Time: 09:35)**

$$\{ E, C_3, C_3^2, C_2, C_2^2 \} \Rightarrow C_3 \text{ point group}$$
 Matrix rep of each symm op and use that to test various properties of the group.

2) What is the point group obtained by adding/deleting a given operation?

$C_3 \text{ point group} + i \text{ operation} \rightarrow \text{New point group?}$

$\{ E, C_3, C_3^2, i, \dots \}$

Group follows closure property.  $C_3 i$  or  $i C_3 = ?$

Find out the matrix rep of each of the elements, and keep finding the products or squares.

So, let us look at another type which is actually a little difficult not difficult but you need little imagination. So now say what is the point group obtained by adding/deleting a given operation. So, let us say you are given a point group let us say you are given a  $C_3$  point group. And now to that  $C_3$  point group let me write down  $C_3$  point group, to this  $C_3$  point group, you are adding a inversion operation.

So, what is the new point group? How do you find out this? So, there can be enormous number of combinations I have just taken one example here but you can have different type of examples. So how do you approach what is the approach if you know the approach you can solve any given problem. So, but you should know the approach for these kinds of problems. So, for  $C_3$  point group what you have is a list on the elements group elements.

You have E, C3, C3 square and on top of that you are now adding i, now adding i is not just adding i so if you add i to this what additional elements are also added that one has to identify. So how do you identify that so the very easy thing is that group always follows closure property group follows closure property. So that means what you have to do is you have to create the products of different elements.

And see what is the resultant which you are getting now that resultant may belong to the already existing element or may give you some additional element. So, for example if we do a C3 into i or i into C3 what do we get? Let us see if we get a new operation. So now that new operation can come here. So how to do that, let us see. So again the easy way is to write down the matrix representation for the two because you do not know how the molecule will change let us say if we have C3 and some molecule which is of C3 point group.

Now if we are adding i operation how do we change the molecule. What is the symmetry of the new molecule? That is impossible to predict. So, best ways to find out the matrix representation of each of the elements and keep finding the products or squares of different elements because that is bound to give you a new element unless all the elements are completed all the elements of the new group are completed. So let us see how does it work out.

**(Refer Slide Time: 13:33)**

$$C_3 = \begin{bmatrix} 1/2 & -\sqrt{3}/2 & 0 \\ \sqrt{3}/2 & 1/2 & 0 \\ 0 & 0 & 1 \end{bmatrix} \quad i = \begin{bmatrix} -1 & 0 & 0 \\ 0 & -1 & 0 \\ 0 & 0 & -1 \end{bmatrix} \quad C_3 i = \begin{bmatrix} 1/2 & -\sqrt{3}/2 & 0 \\ \sqrt{3}/2 & 1/2 & 0 \\ 0 & 0 & -1 \end{bmatrix}$$

$\cos\theta = 1/2 \quad \theta = 60^\circ \quad n = \frac{360}{60} = 6 \quad \downarrow$   
 $S_6$

$S_6 = \{ E, C_3, C_3^2, i, S_6, S_6^5 \}$

$\rightarrow$  test the set of group elements for
 

- ✓ closure property
- ✓ associativity
- ✓ inverse
- ✓ identity

So, for  $C_3$  and  $i$ , for  $C_3$  we have learned that the matrix representation can be written as  $\begin{pmatrix} \cos 120^\circ & -\sin 120^\circ & 0 \\ \sin 120^\circ & \cos 120^\circ & 0 \\ 0 & 0 & 1 \end{pmatrix}$ . And for  $i$ , matrix representation can be written as  $\begin{pmatrix} -1 & 0 & 0 \\ 0 & -1 & 0 \\ 0 & 0 & 1 \end{pmatrix}$ . Now if I do  $C_3$  into  $i$ , what do I get? It is a unit matrix with negative signs so multiplication is easy. So, all you have to do is just change the signs over here. So that means I will get  $\begin{pmatrix} \cos 120^\circ & \sin 120^\circ & 0 \\ -\sin 120^\circ & \cos 120^\circ & 0 \\ 0 & 0 & 1 \end{pmatrix}$ .

Now what kind of a symmetry operation is this? So, if you want to define this matrix representation as a single symmetry operation what kind of operation is this? Now first of all it is not a pure rotational operation why it is not a pure rotational operation? Because a pure rotational operation would never give you  $-1$  in the  $z$ ,  $-1$  corresponding to the  $z$  basis. So that means if  $z$  is getting converted to  $-z$  that means there is a reflection involved.

So, it has to be a rotation and reflection. So now rotation and reflection mean that this is some sort of a rotation  $\times$   $y$ , now what is the angle that angle we can identify by looking at the value so if we have  $\cos \theta$  is equal to half, we have  $\theta$  is equal to you can say  $60^\circ$ . So that means this is if my  $n$  will be  $360 / 60$ , so this will be  $6$  so that means this will be a  $C_6$  kind of rotation this was  $C_3$  rotation this is  $C_6$  rotation now.

Now if this is  $C_6$  rotation and this is  $\sigma_h$  corresponding to it so this would become  $S_6$ . So now what do you have obtained this you have gone to a little higher number of elements. So, you have obtained  $S_6$  now  $S_6$  if you calculate the square of it so that will be  $S_6^2$ . What else do we have?  $S_6^2$ , so that will be  $C_3$ ,  $S_6^4$  will be a  $C_3$  square. So, what you will have is  $S_6^5$  which will be the independent operation.

Now  $S_6^5$  will also come as a product of one of these maybe it will be from  $i$  to  $C_3$  square or so and so forth. Now this follows all the group properties of course you have to test it I am not testing it here I am just telling you once you have identified  $S_6$  you know that  $S_6$  alone would give you  $S_6$  as well as  $S_6^5$ . So, I have included this operation here but what you have to do is you have to test the set of group elements for closure first of all closure property.

And then associativity, so once the closure property is fulfilled, then only you can go for a test for associativity, inverse, and identity. So, these 4 properties have to be fulfilled and then you can say that now the new group is nothing but  $S_6$  point group. So, from  $C_3$  by just adding one symmetry element you have gone to  $S_6$  point group. So that otherwise it is difficult to imagine that what will be the point group by deletion or addition of a symmetry element.

So same thing can be done by addition or for deletion of element also. So again, this is an important question I have seen this coming in different exams. So that is why I thought I will bring it up here.

**(Refer Slide Time: 18:08)**

$\hookrightarrow$   
 ✓ closure property  
 ✓ associativity  
 ✓ inverse  
 ✓ identity

3) What is the group of operations generated by  $S_n$  if  $n$  is even or  $n$  is odd.

$S_4$  ( $n = \text{even}$ ) :  $S_4, S_4^2, S_4^3, S_4^4$      $\{E, S_4, C_2, S_4^3\}$   
 $C_4, C_4^2, C_4^3, C_4^4$   
 $S_4, C_4^2, S_4^3, E$   
 $C_2$

$S_4$  point group

So now let us ask a third question is, what is the group of operations which are generated by  $S_n$  if  $n$  is even or  $n$  is odd. So let us take each of this case with example, so let us say if  $n$  is even. So, let us consider  $S_4$ , so  $n$  is even. So now what are the operations that will be generated? So,  $S_4$  will generate  $S_4, S_4$  square,  $S_4$  cube,  $S_4^4$  now each of this is called as  $C_4$  sigma, so this is an independent operation.

So, we will keep it as  $S_4$  now this will be  $C_4$  square sigma square is  $E$ , so this is nothing but  $C_4$  square and this can be then written as  $C_2$ .  $S_4$  cube can be written as  $C_4$  cube and sigma cube. So, you can simplify it as  $C_4$  cube into sigma. So, nothing can be so you cannot simplify it further.

So, S4 cube will be there S4 to the power 4 will be C4 to the power 4 and sigma to power 4 both our E so you have E.

So, generating operations from S4 you get 4 different elements which is E, S4, C2, S4 cube. Now these are the set of elements which will form S2n or S4, point group. So that is easy to identify, so for n = even if we are generating operations of S4 you will get S4 point group back.

**(Refer Slide Time: 20:29)**

Generating operations from  $S_n$

$$S_4 \text{ (n= even)} = \begin{matrix} S_4 & S_4^2 & S_4^3 & S_4^4 \\ C_4\sigma & C_4^2 & C_4^3\sigma^2 & C_4^4\sigma^4 \\ S_4 & C_2 & S_4^3 & E \end{matrix} \Rightarrow \{E, S_4, C_2, S_4^3\}$$

$C_2$

S<sub>4</sub> point group

$$S_3 \text{ (n= odd)} = \begin{matrix} S_3 & S_3^2 & S_3^3 & S_3^4 & S_3^5 & S_3^6 \\ C_3\sigma & C_3^2\sigma^2 & C_3^3\sigma^3 & C_3^4\sigma^4 & C_3^5\sigma^5 & C_3^6\sigma^6 \\ S_3 & C_2 & \sigma & C_3 & S_3^2 & E \end{matrix}$$

$\{E, S_3, C_3^2, \sigma, C_3, S_3^2\} \Rightarrow C_{3h}$  point group.

Operation of  $S_n \Rightarrow C_{2n}$  point group (for odd n)

Now let us say for n = odd what is the case so let us consider the simple case of 3 because 5 will be too long. So, n = odd, so let us say what are the operations which are generating S3, S3 to the power 2, S3 to the power 3, S3 so we have to keep going till we hit E. So, let us say if we have already hit E at S3 to the power 3 or not. So, S3 will be equal to C3 sigma so which is nothing but S3 again this will be C3 square sigma square.

So sigma square you see so you can write it as C3 square, S3 cube will be C3 cube and sigma cube, so you will have this is C3 cube is E, and sigma square is E, so you are left with one sigma, so you have one sigma over here and what else we have so you are still not got E, so we have to keep going S3 to the power 4, will be C3 to the power 4 and sigma to the power 4, sigma to the power 4 is E and this is C3 to the power cube is E. So, you are left with one C3 operation.

So again, we are not getting E so move further. So, this is C3 to the power 5 and sigma to the power 5, nothing will go to E. So, we are left with C3 square and sigma square. So that would mean you have S3^5 back, S3 to the power 6 you have C3 to the power 6 sigma to the power 6 which is E. So, after that you do not need to generate more operations because that will give you an S3 again.

Now so what we have got is E, S3, C3 square, sigma, C3, S3^5 these are the set of operations which we have got. Now this set of operations what is the point group for this? This will give you a C3h point group. So that means if we are generating operations using S3 axis or Sn axis where n = odd then we will generate Cnh point group. So, in general we can say Sn will give you Cnh point group.

So, operations of Sn where n is odd for odd n we will use Cnh although it appears that it is a S3 axis only then, but still it pops out sigma out of nowhere, pure rotational elements out of nowhere, by just doing operations of S3 you are getting a Cnh point group. So, these are also kind of questions which are asked in different type of exam. So, it is important to cover this. Let us look at one last question and then we can stop for today so let us see.

**(Refer Slide Time: 24:01)**

4) Express operation generated by  $S_5$  and  $S_8$  in conventional notation.

n=odd    n=even

Operation of  $S_5 =$

$S_5$	$S_5^2$	$S_5^3$	$S_5^4$	$S_5^5$	$S_5^6$	$S_5^7$	$S_5^8$	$S_5^9$	$S_5^{10}$
=	$C_5^4 \sigma^2$	$C_5^3 \sigma^2$	$C_5^2 \sigma^2$	$C_5 \sigma^2$	$\sigma^2$	...	...	...	...
$S_5$	$C_5^2$	$S_5^3$	$C_5^4$	$\sigma$	...	...	...	...	...

Operation of  $S_8 = S_8, S_8^2, S_8^3, S_8^4, S_8^5, S_8^6, S_8^7, S_8^8$ .

So, the fourth question is express operations generated by S5 and S8 in conventional notations. So now this is easy now that you have learned how to generate different operations of S5. So

basically, here they have taken 2 examples where  $n$  is odd and  $n$  is even. So, for even  $n$ , you have to keep going up to, so,  $S_8$  to the power of 8 and for  $S_5$  we have to go up to the power of 10. So why I am saying that let us just look at it again. So, operations of  $S_5$ .

So, what all operations  $S_5$  will generate and you have to put it in conventional notation, what is the conventional notation? So,  $S_5$ ,  $S_5$  square,  $S_5$  cube,  $S_5^4$ ,  $S_5^5$ ,  $S_5^6$ ,  $S_5^7$ ,  $S_5^8$ ,  $S_5^9$ ,  $S_5^{10}$  we have earlier seen that only when we hit  $S_5$  up to our  $S_n$  raised to the power  $2n$  we will hit  $E$  otherwise we will not hit  $E$ . So, we have to keep going at least up to the  $2n$  one part. So,  $S_5$  is nothing but  $S_5$ , so there is no change in conventional notation what is  $S_5$  square? So, we have  $C_5$  square into sigma square, now sigma square is  $E$ . So, we can write it as  $C_5$  square.

So, although it is  $C_5$  square but it is an operation generated by  $S_5$ . So, this is what it means by conventional notation. Now again  $C_5$  cube sigma cube. So, this does not conform to anything, so we will keep it as  $S_5$  cube only. Again, this will be  $C_5$  to the power 4, sigma to the power 4, this is cancelled. So, we will be left with  $C_5$  to the power 4,  $C_5$  to the power 5, sigma to the power 5. So, we are left with only sigma and so on so forth. So now you can actually calculate.

So, these are the conventional notations for the operations generated by  $S_5$ . Similarly, we can work out operations of  $S_8$  in the same manner. So here we have to go to  $S_8$  to the power 2,  $S_8$  to the power 3,  $S_8$  to the power 4,  $S_8$  to the power 5,  $S_8$  to the power 6,  $S_8$  to the power 7,  $S_8$  to the power 8. So, this will give you and then you can figure out whether it will be  $S_8$  or  $C_8$  or sigma and so on so forth, or  $E$ . So that is how you can generate different operations by rotation-reflection axis and find out the corresponding conventional notations.

So, we have learned today how to work with different type of problems related to point groups which is which can be sub-group or related to multiplication tables when we are trying to find the closure property and so on and so forth right. So that is all for today. So next let us see what is there for next class. And we will come back with next week's tutorial.
