Lecture 28

Navier-stocks equations and applications

Welcome back to the video course on fluid mechanics. In the last lecture we are discussing about the exact solutions for the navier-stocks equations. The navier-stocks equations, we have derived earlier for the viscous flow and we have seen it is second order non-linear equations only for simplified cases only we can derive the exact solutions.

We have seen few cases like plane poiseuille flow couette flow; also we have seen a simple transient type case where an exact solution can be derived for the navier-stocks equations. In this lecture, further, we will discuss few more naviers the exact solutions which are possible for the navier-stocks equations, these problems are again some of the simplified cases first we will see the case of pie flow the steady state flow in pipes this case is called hagen-poiseuille flow.

(Refer Slide Time: 02:25)

Hagen-Poiseuille Flow

- Let us consider flow through a straight pipe of constant circular section
- For circular sections, cylindrical coordinates are used
- $(x,y,z) \longrightarrow (r,\theta,z)$ and $(u,v,w) \longrightarrow (v_r, v_\theta, v_z)$

- $x = r\cos\theta$; $y = r\sin\theta$; $z = Z$
- $u = v_r\cos\theta$; $v = v_r\sin\theta$; $w = v_z$

Let us consider the flow through a straight pipe of constant circular section. We can see here is a pipe section this is long pipe and the radius is r capital r for the circular section. As we have already seen we have seen in the Navier-Stokes equations two forms one is the Cartesian coordinate forms and second one is the cylindrical coordinate forms pipe is consigned, we are dealing generally we are dealing with the radius length of the pipe and the angles with which we consider.

The cylindrical coordinate system will be better for this type problem, for the Hagen-Poiseuille flow problem here r is the radius of the pipe θ is the angle which we consider. The particular location the length of the pipe which we consider here corresponding to the Cartesian coordinate x y and z , we consider r θ and z and corresponding to the velocity components u v w in x y z direction. We consider v_r velocity θ and v_z correspondingly with respect to this figure we can write x is equal to $r \cos \theta$ and y is equal to $r \sin \theta$ and z is equal to z .

We can write now this u is equal to $v_r \cos \theta$ v is equal to $v_r \sin \theta$ and w is equal to v_z this is the problem structure which we are trying to apply the Navier-Stokes equations, try to get an exact solution for this kind of problem the flow through pipes which is steady state flow that is Hagen-Poiseuille flow.

(Refer Slide Time: 04:12)

Contd..

$\frac{\partial p}{\partial r} = \frac{\partial p}{\partial \theta} = 0$ - pressure is a function of z only

- Consider the axial component of the N-S eqn in cylindrical coordinates:

$$\frac{\partial v_z}{\partial t} + v_r \times \frac{\partial v_z}{\partial r} + \frac{v_\theta}{r} \times \frac{\partial v_z}{\partial \theta} + v_z \frac{\partial v_z}{\partial z}$$

$$= F_z - \frac{1}{\rho} \frac{\partial p}{\partial z} + \nu \left(\frac{\partial^2 v_z}{\partial r^2} + \frac{1}{r} \frac{\partial v_z}{\partial r} + \frac{1}{r^2} \frac{\partial^2 v_z}{\partial \theta^2} + \frac{\partial^2 v_z}{\partial z^2} \right) \quad (1)$$

- As $v_z = v_z(r)$ and $p = p(z)$, partial derivative can be replaced by ordinary derivatives. So,

$$\frac{dp}{dz} = \mu \left[\frac{d^2 v_z}{dr^2} + \frac{1}{r} \frac{dv_z}{dr} \right] \quad (2) \quad \text{B.C: } v_z = 0 \text{ at } r=R$$

$dv_z/dr = 0 \text{ at } r=0$

For this particular problem, since the pressure variation pressure is a function of z only that means with respect to the length of the pipe only, the pressure is varying that we can write $\frac{\partial p}{\partial r}$ and $\frac{\partial p}{\partial \theta}$ they both are 0 that we can write $\frac{\partial p}{\partial r}$ is equal to $\frac{\partial p}{\partial \theta}$ is equal to 0 pressure is the function.

Let us consider the axial component of the navier-stokes equations in the cylindrical coordinates. We have seen earlier the navier-stokes equations cylindrical coordinate; we can write r θ and z component here we consider the axial component of the navier-stokes equations in the cylindrical coordinate system.

As we have seen earlier, this equation the axial component can be written as $\frac{dv_z}{dt} + v_r \frac{dv_z}{dr} + v_\theta \frac{dv_z}{r d\theta} + v_z \frac{dv_z}{dz}$ is equal to $f_z - \frac{1}{\rho} \frac{\partial p}{\partial z} + \mu \left(\frac{d^2 v_z}{dr^2} + \frac{1}{r} \frac{dv_z}{dr} + \frac{1}{r^2} \frac{d^2 v_z}{d\theta^2} + \frac{d^2 v_z}{dz^2} \right)$.

Where f_z is this the body force component for the problem considered as in the previous figure. We consider horizontal pipe where we do not have to consider the body force for this particular problem and we consider the flow to be steady state that this the $\frac{dv_z}{dt}$ term but time dependent term vanishes or this 0 and as the velocity v_z the z direction is varying with respect to the radial direction v_z is a function of $v_z r$ and p is a function of p_z and partial derivative can be replaced by ordinary derivatives.

This equation the time component is gone; we can just simplify this equation with respect to the various assumptions used. We can write as $\frac{dp}{dr}$ is equal to $\mu \left(\frac{d^2 v_z}{dr^2} + \frac{1}{r} \frac{dv_z}{dr} \right)$. The final equation become $\frac{dp}{dr}$ is equal to $\mu \left(\frac{d^2 v_z}{dr^2} + \frac{1}{r} \frac{dv_z}{dr} \right)$. For this pipe flow problem, we can see that pipe is consigned all boundary that means, due to no slip condition at r is equal to capital r we can write v_z is equal to 0.

That means on the pipe boundary the velocity is 0. The v_z is equal to 0 at r is equal to r that is one boundary condition we can see that for pipe flow, as describe here we can see that the velocity variation is parabolic and maximum will be at the center of the pipe. At

this location at r is equal to 0, we can write dv_z by dr is equal to 0 since maximum velocity at the center line at r is equal to 0, we can write at the derivative of the velocity with respect to r dv_z by dr is equal to 0. For this particular problem we have simplified the navier-stokes equations we have derive the boundary conditions now for the simplified problem, we will be trying to find out an exact solution with respect to the various conditions here.

Our aim is to find out the velocity in order to find this velocity. With respect to this earlier equation which derived here, we will integrate equation number two. let us assume dv_z by dr is equal to s , so that we can write equation number two in terms of this s , as ds by dr plus $\frac{1}{r}s$ is equal to $\frac{1}{\mu} \frac{dp}{dz}$ equation number three. From the mathematical test books we can assume indication factor if i is equal to e to the power integral $\frac{1}{r} dr$ this is equal to e to the power $\log e r$ that is equal to r .

(Refer Slide Time: 08:23)

Contd..

- In order to integrate (2), let $dv_z/dr = s$,
- Hence eqn(2) becomes: $\frac{ds}{dr} + \frac{1}{r}s = \frac{1}{\mu} \frac{dp}{dz}$ (3)
- From mathematics, I.F $I = e^{\int \frac{1}{r} dr} = e^{\log r} = r$
- Multiplying both sides by I.F & using integrating by parts rule on LHS

$$rs = \int \frac{1}{\mu} \frac{dp}{dz} r dr + C_1$$

$$rs = \frac{1}{\mu} \frac{dp}{dz} \frac{r^2}{2} + C_1$$

We assume an integration factor if i is equal to r . We will multiply both sides of equation number three by this integration factor, we will use the integrating by parts rules on the left hand side of this equation finally multiplying by the integrating factor if given i is equal to r using the integration by parts, we can write this equation number three as r

into s is equal to integral $\frac{1}{\mu} dp$ by dz r dr plus c_1 where c_1 is a constant of integration.

This again we can write as rs is equal to $\frac{1}{\mu} dp$ by dz r square by 2 plus c_1 finally this equation three is stands from v as this equation here. Also we can write r after substituting for this s here, we can write r into dv_z by dr is equal to $\frac{1}{\mu} dp$ by dz r square by 2 plus c_1 as in equation number four. We have the boundary conditions that we can find out the constant of integration here same at the central line my velocity is maximum that dv_z by dr is equal to 0 at r is equal to 0.

(Refer Slide Time: 09:56)

$$r \frac{dv_z}{dr} = \frac{1}{\mu} \frac{dp}{dz} \frac{r^2}{2} + C_1 \quad \text{--(4)}$$

- With B.C. of symmetry, $dv_z/dr = 0$ at $r=0$, then $C_1=0$
- Integrating (4) and substituting s ,
$$v_z = \frac{1}{\mu} \frac{dp}{dz} \frac{r^2}{4} + C_2 \quad \text{--(5)}$$
- Applying B.C's
$$C_2 = -\frac{1}{\mu} \frac{dp}{dz} \frac{R^2}{4}$$
- Hence velocity distribution
$$v_z = \frac{1}{4\mu} \frac{dp}{dz} (r^2 - R^2) \quad \text{--(6)}$$

That in this from this equation number four, we will get c_1 is equal to 0 then integrating this equation again and substituting s , as we have already seen and we get v_z is equal to $\frac{1}{\mu} dp$ by dz into r square by 4 plus c_2 as in equation number 5, again here the c_2 we can find out by using the boundary condition at r is equal to R we have the velocity is 0 that we will get c_2 is equal to minus $\frac{1}{\mu} dp$ by dz into R square by 4.

This R is a capital; r is a radius of the pipe. Finally we get here this constant of inherent c_2 as c_2 is equal to minus $\frac{1}{\mu} dp$ by dz R square by 4 R , after substituting finally we get the velocity distribution v_z is equal to $\frac{1}{4\mu} dp$ by dz into s square small r square

minus capital r square this expression equation six gives the velocity distribution at various location small r is the distance from the central line

At various locations we can substitute and get the velocity distribution as v_z is equal to 1 by $4\mu \frac{dp}{dz}$ into r^2 minus capital r^2 where r is the radius of the pipe.

We can drive the velocity distribution as for as the pipe flow is consigned now once we get this we can derive the various other parameters like discharge and other parameters. This equation for v velocity distribution we can write v is equal to minus 1 by $4\mu \frac{dp}{dz}$ into r^2 minus r^2 equation six a, the maximum velocity at the center and this is given, we here we can substitute r is equal to 0 that gives u_{\max} is equal to minus 1 by $4\mu \frac{dp}{dx}$ into r^2 as in equation number seven.

(Refer Slide Time: 12:09)

Contd..

- i.e. $v = -\frac{1}{4\mu} \frac{dp}{dz} (R^2 - r^2)$ (6A) Put $v = u$ $Z = X$
- The maximum velocity occurs at the center and is given by $u_{\max} = -\frac{1}{4\mu} \frac{dp}{dx} R^2$ (7)
- From 6A and 7: $u = u_{\max} \left[1 - \left(\frac{r}{R} \right)^2 \right]$ (8)
- Eqn(8) is the most commonly used equation for the velocity distribution for laminar flow through pipes.
- Discharge through an elementary ring of dr thickness at radial distance r is $dQ = u \cdot 2\pi r \cdot dr$

If you use equation number six and seven, here we assume the logical direction coming back in the in this direction of u is equal to we can write the velocity variation u is in terms of the maximum velocity, u is equal to u_{\max} into 1 minus r by r power square as in equation number eight. This equation eight is the most commonly used equation for the velocity for laminar flow through pipe; here our assumption is that flow is steady state laminar and same the pipe is parallel horizontal direction.

All these assumptions we applied and only that, we could use the navier-stocks you simplified from the navier-stocks equation to derive on exact solution. Once we get the velocity distribution we can find out the discharge, the discharge through an elementary ring of dr thickness at radial distance r is dq is equal to u into 2 pie r dr, we can write dq is equal to with respect to after we substitute for u dq is equal to u_{\max} into 1 minus r by r whole square 2 pie r dr.

Total discharge we can integrate integral dq that is equal to integral 0 to r u_{\max} 1 minus r by r whole square into 2 pie r dr that is equal to pie by 2 into u_{\max} r square and average velocity once we get the discharge average velocity, we can find out by just dividing by the area of procession.

(Refer Slide Time: 13:28)

Contd..

- i.e. $dQ = u_{\max} \left\{ 1 - \left(\frac{r}{R} \right)^2 \right\} 2\pi r dr$
- Total Discharge,

$$Q = \int dQ = \int_0^R u_{\max} \left\{ 1 - \left(\frac{r}{R} \right)^2 \right\} \times 2\pi r dr = \frac{\pi}{2} u_{\max} R^2$$
- Average velocity of flow,

$$\bar{u} = \frac{Q}{A} = \frac{\frac{\pi}{2} u_{\max} R^2}{\pi R^2} = \frac{u_{\max}}{2} = -\frac{1}{8\mu} \frac{\partial p}{\partial x} \times R^2$$
- The pressure difference between two sections

$$p_1 - p_2 = \frac{8\mu \bar{u}}{R^2} (x_2 - x_1) = \frac{8\mu \bar{u} L}{R^2} = \frac{32\mu \bar{u} L}{D^2}$$

Average velocity is \bar{u} is equal to q by a, from this expression we can write q q by a is equal to pie by 2 u_{\max} r square by pie r square that is equal to u_{\max} by 2 that is equal to minus 1 by 8 mu dp by dx into r square this will be the average velocity and the pressure difference between the two sections. We have found the velocity distribution we got an expression for velocity we derived an expression for the discharge if you want to find out the pressure difference between two points two sections we can just use that equation.

P_1 minus p_2 since our earlier velocity equation is with respect to the pressure that we can write p_1 minus p_2 is equal to $8 \mu u$ bar by r square into x_2 minus x_1 that is the distance from one section two. Another section that is equal to $8 \mu u l$ by r square you will the distance between sections one to two, we can write p_1 minus p_2 is equal to $8 \mu u$ bar by r square. We can write in terms of diameter as this is equal to $32 \mu u$ bar l by d square.

What we did here is the navier-stokes equation, we simplified for the given conditions with respect to boundary condition we derive an exact solution for the velocity and from the velocity we can determine various other parameters like pressure variations from one section to another we can find out the discharge like this. We can utilize the navier-stokes equation for the simplified case we can derive an exact solution for the problem this way two more other problems we will discuss here. This case is the hagen-poiseuille flow where we derived the expression for the velocity variation, we have seen the pipe flow, we will check some more and try to derive the exact solution for two more other problems another typical problem which is generally used mechanical engineering is flow between concentric rotating cylinders.

(Refer Slide Time: 16:47)

This is very common problem in mechanical engineering our problem is that there are two or thirty cylinders and the fluid is between this two rotating cylinder our aim is to

derive an expression for the velocity variation for the rotating cylinder we start with navier-stokes equation we will apply all the simplifications. We want to derive an analytical solution here, the problem is we consider a flow of fluid contained between the two concentric cylinders as shown in figure here this is the first cylinder of radius r_1 and here this is the second cylinder of radius r_2 and the flow is between this two cylinders and both the cylinders are rotating like this with first one with radius the angular velocity of ω_1 and second one with an angular velocity of ω_2 .

Angular speed of the cylinders are ω_1 and ω_2 and radius are r_1 and radius are r_2 as in figure this kind of problem after sufficient time is a once we start the machine it maybe transient the nature of the flow problem maybe transient nature but after some time the problem become flow become steady state that we can assume the case of steady state here for this typical the flow of rotating cylinders constant rotating cylinders now in the spacing $r_2 - r_1$ is small strictly speaking and the Reynolds number Re is equal to $\rho(\omega_2 - \omega_1)(r_2 - r_1)^2 / \mu$ if it is less than or equal to 1 and you can see that the 1 d flow.

(Refer Slide Time: 17:54)

Contd..

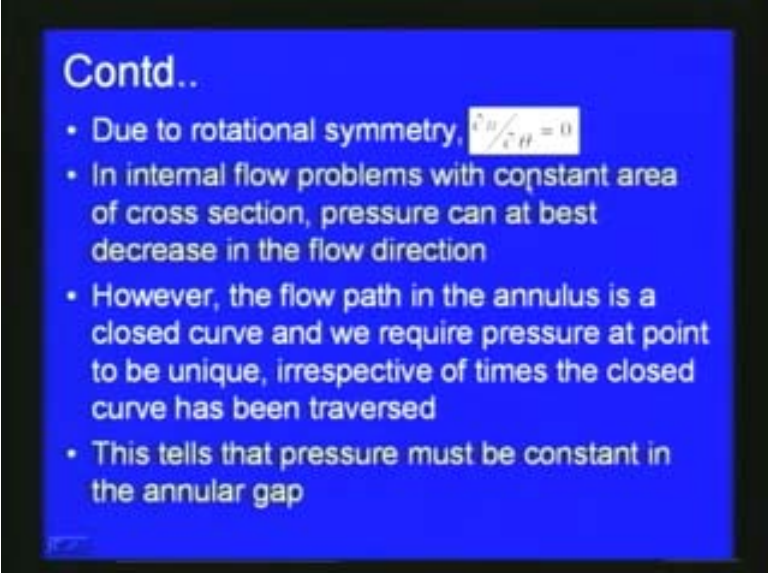

- Now if the spacing $(R_2 - R_1)$ is small, (strictly speaking, $Re = [\rho(\omega_2 - \omega_1)(R_2 - R_1)^2] / \mu \leq 1$)
- 1D flow in angular direction is set up
- We assume, $Re \leq 1$ here, as at high Re flow becomes unsteady, 3D and turbulent
- Let, $\mathbf{u} = (u, v, w)$ be the component of velocity in $(r, \theta \text{ and } z)$ directions
- The cylinders are assumed to be long having no through flow and end effect
- Hence, $w = 0$; and all derivative of $w = 0$

The flow is we can consider as one dimensional flow in angular direction that is typical problem we can consider the flow as 1 d flow angular direction

If you assume here if Reynolds number is less than equal to 1 as at high Reynolds number flow become unsteady and three dimensional turbulent, we are considering this case only for Reynolds number less than or equal to 1 since when we consider the Reynolds higher Reynolds number the flow is generally unsteady, we have to consider three dimensional and turbulent flow depending upon the case.

Here we consider the Reynolds number as less than or equal to 1 and here let the velocity vector u correspondingly in x y z direction will be w be the components of velocity in r θ and z directions here the velocity component in r θ and z direction, we are writing as u v and w the cylinders are assuming to be long having no flow no through flow and end effect here for this typical problem before using the navier-stocks equations and simplifying and get trying to get an exact location we assume that there are now end effect the, we are having no through flow and we can write in this typical case w is equal to 0 and all derivative w is equal to 0 where w is the velocity component in the z direction for this typical problem now due to the rotational symmetry here in the previous slide you can see that there is symmetric with respect to the rotation

(Refer Slide Time: 19:53)

Contd..

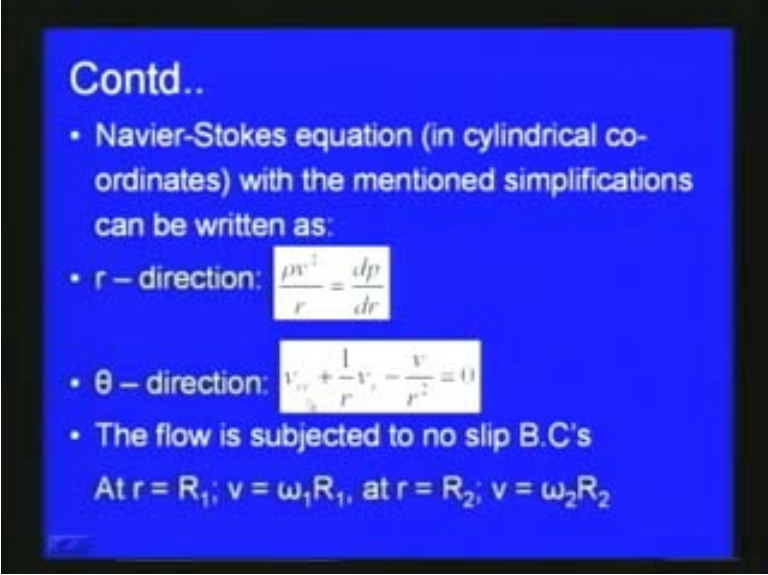

- Due to rotational symmetry, $\frac{\partial u}{\partial \theta} = 0$
- In internal flow problems with constant area of cross section, pressure can at best decrease in the flow direction
- However, the flow path in the annulus is a closed curve and we require pressure at point to be unique, irrespective of times the closed curve has been traversed
- This tells that pressure must be constant in the annular gap

Due to the rotational symmetry we can write $\frac{\partial u}{\partial \theta}$ is equal to 0 in internal flow problems with constant area cross section pressure can at best decrease in the flow

direction for this kind of problem however the flow path in the annulus is a closed curve and we require pressure at point to be unique irrespective of times the closed curve has been traversed these are the assumptions which we used for this problem this tells that pressure must be constant in the annular gap we are using certain assumptions like $\frac{\partial u}{\partial \theta}$ is equal to 0, we assume that flow path in the annulus is a closed curve we also assume that pressure must be constant in the annular gap.

For this conditions now we simplify the Navier-Stokes equation, as we have already seen the curve flow is we are assuming the flow is to be steady state various assumption, we have seen if you utilize all these assumption then we can write the Navier-Stokes equations cylindrical coordinate with the mentioned simplification in the r direction. We can write ρv^2 by r is equal to $\frac{dp}{dr}$ in θ direction, we can write the second derivative of the velocity $\frac{d^2 v}{dr^2} + \frac{1}{r} \frac{dv}{dr} - \frac{v}{r^2}$ is equal to 0 this two substitute store the second derivative and this is the first derivative.

(Refer Slide Time: 20:59)

Contd..

- Navier-Stokes equation (in cylindrical coordinates) with the mentioned simplifications can be written as:
- r – direction: $\frac{\rho v^2}{r} = \frac{dp}{dr}$
- θ – direction: $\frac{v}{r^2} + \frac{1}{r} \frac{dv}{dr} - \frac{v}{r^2} = 0$
- The flow is subjected to no slip B.C's
At $r = R_1$; $v = \omega_1 R_1$, at $r = R_2$; $v = \omega_2 R_2$

Vary plus $\frac{1}{r} \frac{dv}{dr}$ minus $\frac{v}{r^2}$ is equal to 0 the flow is subjected to no slip boundary condition that we can write at r is equal to r_1 v is equal to $\omega_1 r_1$ and at r is equal to r_2 v writ V is equal to $\omega_2 r_2$, these are the boundary conditions for this

problem and the navier-stokes equation r simplified in this four. We have already seen as in the previous case here we have this equation theta direction we have got a second derivative the velocity.

We can integrate to solve is this equation you there be 2 constant c_1 and c_2 finally we can get a solution v_r is equal to $\frac{1}{4} r^2$ into c_1 into r^2 by 2 plus c_2 this is the expression for the velocity variation for this typical problem here the problem is like this, we have already seen this r is the difference between this r_2 to r_1 that is what we have small r is between the difference between r_2 to r_1 this the solution.

Finally, the solution becomes v_r is equal to $\frac{1}{4} r^2$ c_1 into r^2 by 2 plus c_2 and c_1 we can obtain two boundary conditions and use this to get the constant c_1 and c_2 , c_1 is equal to $\frac{2}{\omega_2 r_2^2 - \omega_1 r_1^2}$ and c_2 is equal to $\frac{\omega_2 r_2^2 - \omega_1 r_1^2}{\omega_2 r_2^2 - \omega_1 r_1^2}$ like this, we can derive the expression drive an expression for the velocity variation for the flow between the to constant a cylinders.

Here what we did is we applied various simplifications for the problem and we got a simplified form of the navier-stokes equations we integrated the equations that we can get a solution. Finally we got a solution for the velocity variation that can be used find out various other parameters, these kinds of problem there is application for to a viscometers here how we apply this solution to viscometer application to viscometer which measures the viscosity of liquid.

(Refer Slide Time: 23:52)

Application to a Viscometer

- Viscometer measures the viscosity of liquid
- It is a typical arrangement of a stationary inner cylinder (i.e. $\omega_1=0$) and rotating outer cylinder
- Hence the velocity profile becomes:

$$v = \frac{\omega_2 R_2^2}{(R_2^2 - R_1^2)} \left(r - \frac{R_1^2}{r} \right)$$

- Wall shear stress on the inner cylinder,

$$\tau_w = \mu \left[r \frac{d}{dr} \left(\frac{v}{r} \right) \right]_{r=R_1} = \mu \left(\frac{dv}{dr} \right)_{r=R_1} = \frac{2\mu\omega_2 R_2^2}{R_2^2 - R_1^2}$$

Here the next slide shows how a schematic sketch of viscometer, this is schematic sketch of the viscometer here now it is a typical arrangement of a stationary inner cylinder that we can assume ω_1 is equal to 0 the ambient velocity ω_1 is equal to 0 and rotating outer cylinder hence the velocity profile, with respect to our earlier equation which we derived here the velocity profile we can write v is equal to $\omega_2 r^2$ square divided by r^2 square minus r_1 square into small r minus r_1 square by r , we can get the wall shear stress on the inner cylinder can be derived as by using newton's second law Newton law viscosity, here we have got v we can use the newton's law viscosity to get the wall shear stress on the inner cylinder.

Toe w is equal to μ into $r \frac{d}{dr} \left(\frac{v}{r} \right)$ that is equal to $\mu \frac{dv}{dr}$ by dr at r is equal to r_1 we get an expression for the wall shear stress on the inner cylinder as $2\mu\omega_2 r^2$ square divided by r^2 square minus r_1 square.

(Refer Slide Time: 24:18)

Contd..

- The solution for v can be given as:

$$v(r) = \frac{1}{r} \left(c_1 \frac{r^2}{2} + c_2 \right)$$

- Where, $c_1 = \frac{2(\omega_2 R_2^2 - \omega_1 R_1^2)}{(R_2^2 - R_1^2)}$ and

$$c_2 = -\frac{(\omega_2 - \omega_1) R_1^2 R_2^2}{(R_2^2 - R_1^2)}$$

Once we get the velocity we can find out various parameters like shear stress on the wall and other parameters, what we derive for the concentric cylinder problem, the velocity expression can be directly utilized for the viscometer which we have already seen here for the torque can be measured by a torsion wire.

(Refer Slide Time: 25:51)

Contd..

- This torque can be measured by a torsion wire, whose stiffness is known.
- Knowing the geometry of the apparatus, the viscosity can be determined from the formula,

$$k(\Theta) = \frac{4\pi R_1^2 R_2^2}{(R_2^2 - R_1^2)} \mu \omega_z L$$

k is torsional Stiffness of the wire and
 Θ is angular deflection

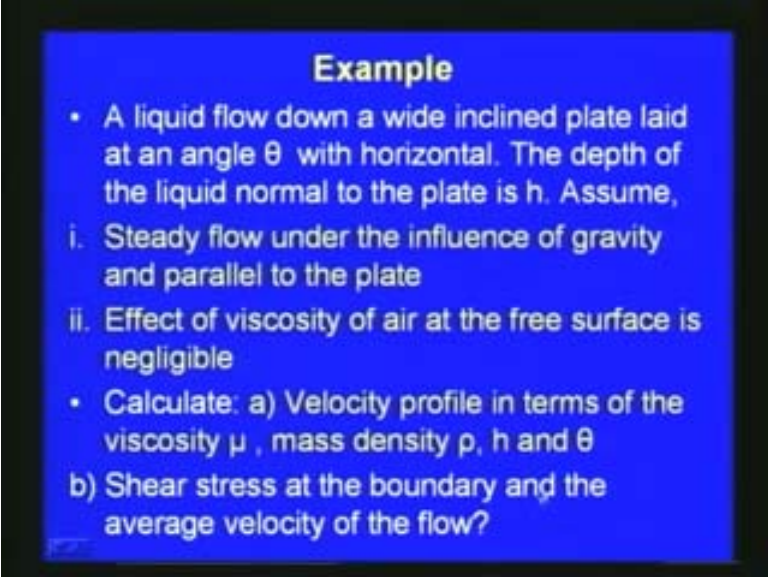

Schematic Sketch of Viscometer

Here the problem is the viscometer problem, we have it is this cylinder is suspended with respect to a wire here, this torque can be measured by a torsion wire whose stiffness is knowing the geometry of the apparatus the viscosity, can be determined from the formula $K \theta$ is equal to $4 \pi r_1^2 r_2^2$ divided by $r_2^2 - r_1^2$ into $\mu \omega$ into l Where θ is the angular deflection and k is the torsional stiffness of the wire like this, we can find out the other parameters for these kinds of problem.

Here we applied the concentric the equations derived for the flow between the concentric cylinders; we work expression for the velocity and the shear stress and other parameters for these kinds of problem. This is a typical problem which we started with the navier-stocks equation simplified the equations we derive the expression for velocity and other parameters. Finally, before closing this exact solution for navier-stocks equation we will consider one more example. The example problem is the statements like this a liquid flow down a wide inclined plate at an angle θ with horizontal.

(Refer Slide Time: 26:57)

Example

- A liquid flow down a wide inclined plate laid at an angle θ with horizontal. The depth of the liquid normal to the plate is h . Assume,
 - i. Steady flow under the influence of gravity and parallel to the plate
 - ii. Effect of viscosity of air at the free surface is negligible
- Calculate: a) Velocity profile in terms of the viscosity μ , mass density ρ , h and θ
 b) Shear stress at the boundary and the average velocity of the flow?

The depth of the liquid normal to the plate is h asses steady flow under the influence of gravity and parallel to the plate the effect of viscosity of air at the free surface is negligible. We have to find out the velocity profile in terms of the viscosity μ mass

density ρ the h and θ and also we have to find out the shear stress at the boundary and the average velocity of the flow this is the problem is defined in this figure.

(Refer Slide Time: 27:43)

Here we have what an inclined plate and the flow is taking place above the plate the thickness of the flow is h and the angular inclined of the plate is θ , here comparing to the earlier problem like plane poiseuille flow or the other kinds of the just flow plate, here the plate inclined, we have to consider the body force. This typical the problem is we have to consider the body force this kinds of problem here our aim is to use the navier-stocks equations then we simplify the navier-stocks equation, we want to get an exact solution for this kind of problem.

The solution as the plate is wide the z direction need not to be considered, we can see that we consider wide plate this z direction need not be consider and here we assume the flow to be steady $\frac{\partial}{\partial t} = 0$ and flow is steady the terms in $\frac{\partial}{\partial t}$ become 0, we assume that the flow is parallel to the plate that is x axis.

(Refer Slide Time: 28:43)

Solution

- As the plate is wide, the Z- direction need not to be considered
- As the flow is steady, $\frac{\partial}{\partial t} = 0$
- Since the flow is parallel to plate, i.e. x- axis, so $\frac{\partial u}{\partial y} = 0$ and $u_z = 0$
- The pressure gradient $\frac{\partial p}{\partial x} = 0$ as the flow takes place at a constant depth h.
- The Body forces cannot be neglected
- If "Z" is the vertical direction, the potential per unit mass due to body force is (gz)

We can write $\frac{\partial u}{\partial x}$ is equal to 0, that u is equal to 0 this is the third assumption also the pressure gradient $\frac{dp}{dx}$ is equal to 0. As the flow takes place at a constant depth h these are the assumptions for the problem once the problem statement is known, we are trying to see that what are the assumptions we can forward such that we can simplify the equations with respect to the various assumptions here for this typical problem. We assuming the flows to be steady flow is parallel to plate the pressure gradient is $\frac{dp}{dx}$ is equal to 0.

These are the assumptions essential assumptions for this problem that we can simplify our equation but here, compare to the earlier problem which we discussed here the body force cannot be neglected, as I mentioned the plate is inclined for the inclined plate you can see that there will be always the body force effect z is the vertical direction the potential per unit mass due to the body force we can write as gz .

With respect to this figure, we can write the potential per unit mass due to body force is gz finally the components of the body force in x and y direction we can write as in the body force in x direction this minus $\frac{dz}{dx}$ by $\frac{dz}{dx}$

That can be written as minus $\frac{dz}{dx}$ the access into gravity $\frac{dz}{dx}$ by $\frac{dz}{dx}$ is equal to $g \sin \theta$ and y is equal to minus $\frac{dz}{dy}$ by $\frac{dz}{dy}$ that is equal to minus $g \cos \theta$.

(Refer Slide Time: 30:41)

Contd..

- The components of the body force in X and Y directions are:

$$X = -\frac{\partial g_x}{\partial x} = -g \times \frac{\partial z}{\partial x} = g \sin \theta \quad \text{and}$$

$$Y = -\frac{\partial g_y}{\partial y} = -g \times \frac{\partial z}{\partial y} = -g \cos \theta$$

- N-S Eqn of motion becomes,

$$g \sin \theta + \mu \frac{d^2 u_x}{dy^2} = 0 \quad \dots(1) \quad \text{and}$$

$$-g \cos \theta - \frac{1}{\rho} \frac{dp}{dy} = 0 \quad \dots(2)$$

Now we use all these assumptions and finally we can get the navier-stocks equations in the following form: the navier-stocks equations become: $g \sin \theta + \mu \frac{d^2 u_x}{dy^2} = 0$ equation number one and second equation is $-g \cos \theta - \frac{1}{\rho} \frac{dp}{dy} = 0$, equation number two here due to our assumptions all other assumptions like this steady state and flow is parallel to the plate and the flow with is larger, we can consider the z direction need not to be consider.

Due to all this assumptions, all other times we can neglect and finally we have simplified the navier-stocks equation in the form of equation number one and two. Our aim for this problem is to find out the velocity distribution u_x here you can see that equation is $\frac{d^2 u_x}{dy^2}$ by in terms of $\frac{d^2 u_x}{dy^2}$, as we did in the previous case we would see what are the boundary conditions, we would work for integration such that we will get the expression for the pressure hand velocity

For steady uniform flow parallel to the plate at a constant depth h we already seen $\frac{\partial}{\partial t}$ is equal to 0 $\frac{\partial u}{\partial x}$ is equal to 0 and u_y is equal to 0 and $\frac{dp}{dx}$ is equal to 0 $\frac{dp}{dx}$ is equal to 0.

(Refer Slide Time: 31:49)

Contd..

- For steady, uniform flow parallel to the plate, at a constant depth h , $\frac{\partial \bar{u}}{\partial t} = 0, \frac{\partial \bar{u}}{\partial x} = 0, \frac{\partial \bar{u}}{\partial y} = 0, \frac{\partial p}{\partial x} = 0$
- Hence from (2): $\frac{d\bar{u}}{dy} = -\rho g \cos \theta$
- On integration: $p = -\rho g y \cos \theta + c$
- At $y = h$, $p=0$, because the pressure is atmosphere, hence, $c = \rho g h \cos \theta$
- So, we have, $p = \rho g \cos \theta (h-y) \dots(3)$

From equation number two, this equation number two become dp by dy is equal to minus $\rho g \cos \theta$ this equation number two, we can integrate such that we get p is equal to minus $\rho g y \cos \theta$ plus c the constant of integration, we get an expression for the pressure in terms of the that y p is equal to minus ρ the ρ is the density of the fluid minus ρg into y into $\cos \theta$ plus c here we to find out this c we will use the boundary condition.

At y is equal to h p is equal to 0 because the pressure is atmosphere, that we can write c is equal to $\rho g h \cos \theta$, now if you sub apply this c here in this equation, we get p is equal to $\rho g \cos \theta$ into h minus y . This is the expression for this flow problem. We got an expression for the pressure as p is equal to $\rho g \cos \theta$ into h minus y the standard procedure of integration used we applied the boundary condition to get the expression for p . This expression three is the pressure distribution for the flow our aim is to get the velocity distribution also from equation one, we can integrate twice with respect to y that gives first integration gives du_x by dy is equal to minus $g \sin \theta$ by new into y plus c_1 equation number four.

(Refer Slide Time: 33:35)

Contd..

- Eqn(3) gives the pressure distribution for the flow
- From eqn (1), integrating twice w.r.t y yields,

$$\frac{du_x}{dy} = -\frac{\rho}{\mu} \frac{\sin\theta}{2} y + C_1 \quad \dots(4)$$
 and

$$u_x = -\frac{\rho}{\mu} \sin\theta \frac{y^2}{2} + C_1 y + C_2 \quad \dots(5)$$
- B.C's: at $y = 0$, $u_x = 0$, which gives $C_2 = 0$
 at $y = h$, $\frac{du_x}{dy} = 0$ which gives $C_1 = \frac{\rho g h \sin\theta}{\mu}$
- So expression for velocity

$$u_x = -\frac{\rho}{\mu} \sin\theta \frac{y^2}{2} + \frac{\rho g h \sin\theta}{\mu} y$$

Once again in the derivative we get u_x is equal to minus g by new into sine theta into y square 2 plus $c_1 y$ plus c_2 finally we got equation number five, here we have got constant of integration c_1 and c_2 we can utilize the boundary conditions the boundary conditions are at y is equal to 0 u_x is equal to 0 which gives c_2 is equal to 0 and that y is equal to h $\frac{du_x}{dy}$ is equal to 0 that which gives c_1 is equal to $gh \sin\theta$ by new.

Finally we can get an expression for velocity as u_x is equal to minus g by new sine theta into y square by 2 plus gh by new sine theta into y after substituting the boundary condition, we got c_1 and c_2 the integration constant, we work finally the expression for the velocity u_x is equal to minus g by new sine theta y square by 2 plus gh by new sine theta into y now this can be simplified as u_x is equal to $g \sin\theta$ by 2 new into 2 hy minus y square or we can write u_x is equal to $\frac{\rho g \sin\theta}{2\mu} (2hy - y^2)$. This is the final expression for the velocity for this particular problem, we got the velocity variation as $\frac{\rho g \sin\theta}{2\mu} (2hy - y^2)$, once we get the velocity we can use Newton's law viscosity to get the shear stress shear stress at the boundary we can write τ_0 is equal to $\mu \frac{du_x}{dy}$ at y is equal to 0.

(Refer Slide Time: 35:08)

Contd..

- i.e. $u_y = \frac{g \sin \theta}{2\nu} (2hy - y^2)$
- Or, $u_y = \frac{\rho g \sin \theta}{2\mu} (2hy - y^2) \dots (6)$
- Now, for the Shear stress at the boundary.

$$\tau_0 = \mu \left(\frac{du}{dy} \right)_{y=0} = \mu \left(g \frac{\sin \theta}{\nu} (h - y) \right)_{y=0} = \rho g h \sin \theta$$

$\tau_0 = \rho g h \sin \theta$ is the formula for shear stress at the boundary

That gives mu into g sine theta by mu into h minus y at y is equal to 0, that gives rho g h sine theta. Finally, we got the expression for the shear stress at the boundary tau 0 is equal to rho gh sine theta tau 0 this is the formula for the tau 0 is rho gh sine theta this is the formula for the shear stress at the boundary.

(Refer Slide Time: 36:01)

Contd..

- The formula $\tau_0 = \rho g h \sin \theta$ is a very important relation used in problem involving sediment transport in open channels
- Average velocity of flow, $v = (q/h)$
- q is flow per unit width $= \int_0^h u_y dy = \int_0^h \frac{\rho g \sin \theta}{2\mu} (2hy - y^2) dy$
- Hence, $q = \frac{\rho g h^3 \sin \theta}{3\mu}$ and $v = \frac{\rho g h^2 \sin \theta}{3\mu}$

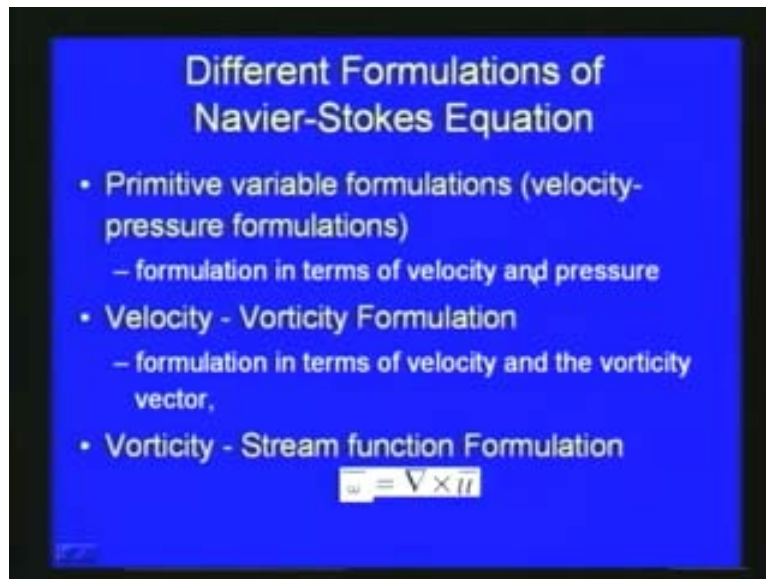

This is a very important relation used in your problem like sediment transport in open channel. Using this expression, we can see how settlement of the sediment takes place. In sediment transport in open channel, we can use this expression if you want to find out the average velocity of flow for this particular problem. v is equal to q by h where q is the flow per unit width. q is equal to $\int_0^h u_x dy$.

That is equal to $\int_0^h \rho g \sin \theta \left(\frac{\mu}{2} h^2 - y^2 \right) dy$. From this expression, we will get q is equal to $\frac{\rho g h^3 \sin \theta}{3 \mu}$ and the average velocity \bar{v} is equal to $\frac{\rho g h^2 \sin \theta}{3 \mu}$. These are the various expressions. Finally, by using various assumptions, we simplified the Navier-Stokes equation, we got the simplified Navier-Stokes equation. Then we integrated to get an expression for the velocity. We found the other parameters like a shear stress, discharge per unit width, by the various constants of integrations we are found by using the boundary conditions.

Like this, various problems can be attempted wherever possible, wherever we can simplify in the Navier-Stokes equations and the problem is simple that we can try for an analytical solution by putting forward various assumptions using the boundary condition. Like this, few more exact solutions are available for the Navier-Stokes equations. But we will not discuss further since we have already seen a few typical cases. Before further going to the applications of Navier-Stokes equations, we will discuss different formulations for Navier-Stokes equations.

We have seen the most commonly used formulation of the Navier-Stokes equations which we have derived earlier in two-dimensional and we ascended the equations to two, three dimensions. In literature, if you go through various research papers and various literatures on Navier-Stokes equations, we can see a few more other kinds of formulations for the Navier-Stokes equations. These different formulations have been derived by using various actions and we can see that commonly three typical formulations are used in literature. First one is the primitive variable formulations or it is velocity-pressure formulations.

(Refer Slide Time: 38:14)

That is what we have discussed and we have derived earlier here the formulation is in terms of velocity and pressure the equations the navier-stocks equations are in terms of the velocity and pressure. These primitive variables are used like velocity and pressure that is why the formulations are called primitive variable formulations. Second kind of generally used the formulation is called velocity vorticity formulations.

Here the formulation for the navier-stocks equations in terms of velocity and the vortices that commonly used navier-stocks equations in terms of vorticity and stream functions it is called vorticity stream function. Formulation here the vorticity $\vec{\omega}$ is defined as $\nabla \times \vec{u}$ where \vec{u} is the velocity vector like this three typical formulations, the common three formulations are used in literature. We will see the various equations used for all this three formulations and the first one is the velocity pressure formulations the already we have derive the equations the equations. For example if you consider in two-dimensional case the equations are the continuity equations even the ∇u_x by ∇y plus ∇v by ∇y is equal to 0.

(Refer Slide Time: 40:13)

Velocity- Pressure Formulations

$$(a) \frac{\partial u}{\partial x} + \frac{\partial v}{\partial y} = 0$$

$$(b) \rho \left(\frac{\partial u}{\partial t} + u \frac{\partial u}{\partial x} + v \frac{\partial u}{\partial y} \right) = - \frac{\partial p}{\partial x} + \rho g_x + \mu \left(\frac{\partial^2 u}{\partial x^2} + \frac{\partial^2 u}{\partial y^2} \right)$$

$$(c) \rho \left(\frac{\partial v}{\partial t} + u \frac{\partial v}{\partial x} + v \frac{\partial v}{\partial y} \right) = - \frac{\partial p}{\partial y} + \rho g_y + \mu \left(\frac{\partial^2 v}{\partial x^2} + \frac{\partial^2 v}{\partial y^2} \right)$$

- In 2D

Then we have two moment equations, which we have all to derive here the equations are: rho into del u by del t plus u into del u by del x plus v into del u by del y is equal to minus del p by del x plus rho g_x plus mu into del square u by del x square plus del square u by del y square and third equation is rho into del u by del t plus u into del v by del x plus v into del v by del y is equal to minus del p by del y plus rho g_y plus mu into del square v by del x square plus del square v by del y square.

These three equations including the continuity equations and two boundary equations are the equations using the velocity pressure formulations for the navier-stokes equations and this equation are called primitive formulations and most commonly used navier-stokes equations for most of the fluid flow problem. The second one the velocity vorticity formulations here, we transform as we have already derive the primitive very formulation that we can transform in terms of another important variable for vorticity. Finally we get the equations in terms of velocity and vorticity, if you consider three-dimensional formulations then, if the velocity vectors are u v and w and the vorticity vectors are psi eta and psi as written here.

(Refer Slide Time: 41:44)

Velocity - Vorticity Formulation

- In 3D: $\bar{u} \rightarrow u, v, w$ and $\bar{\omega} \rightarrow \xi, \eta, \zeta$

$$\frac{\partial \bar{\omega}}{\partial t} + \bar{u} \cdot \nabla \bar{\omega} = \bar{\omega} \cdot \nabla \bar{u} + \frac{1}{Re} \nabla^2 \bar{\omega} \quad (a)$$

$$\nabla^2 \bar{u} = -\nabla \times \bar{\omega} \quad (b)$$

- In 2D: $\frac{\partial \omega}{\partial t} + u \frac{\partial \omega}{\partial x} + v \frac{\partial \omega}{\partial y} = \frac{1}{Re} (\nabla^2 \omega) \quad (a)$

$$\nabla^2 u = -\frac{\partial \omega}{\partial y} \quad (b) \quad \text{where, } \omega = \frac{\partial v}{\partial x} - \frac{\partial u}{\partial y}$$

$$\nabla^2 v = \frac{\partial \omega}{\partial x} \quad (c)$$

Then the equations I am not going to the derivations of this equations the derivation of equation we can see various fundamental books, where the navier-stokes equations are derive and other research papers finally the equations are generally express like this.

This first one is the vorticity transport equation $\frac{\partial \omega}{\partial t}$ here ω bar is the vorticity vector $\frac{\partial \omega}{\partial t}$ plus u bar dot $\nabla \omega$ bar is equal to ω bar dot ∇u bar plus $\frac{1}{Re} \nabla^2 \omega$ bar, here Re is the Reynolds number ω bar is the vorticity vector and u bar is the velocity vector.

This is one equation using the velocity vorticity formulation and second equation we use $\nabla^2 u$ bar is equal to minus $\nabla \times \omega$ bar, as given in this equation b there are two equations in the vector, you are formed as given in equations a and b. This equation, for example if you consider two dimension problems that we can this equations we can write as for two dimensions ω is the vorticity $\frac{\partial \omega}{\partial t}$ plus u into $\frac{\partial \omega}{\partial x}$ plus v into $\frac{\partial \omega}{\partial y}$ that is equal to $\frac{1}{Re} \nabla^2 \omega$ as in this equation this corresponding to this equation, here in two dimensions we can write $\nabla^2 u$ is equal to minus $\frac{\partial \omega}{\partial y}$ and same $\nabla^2 v$ is equal to minus $\frac{\partial \omega}{\partial x}$ as in the equation and where ω is equal to $\frac{\partial v}{\partial x} - \frac{\partial u}{\partial y}$.

This equations use the velocity vorticity formulation for the navier-stocks equations in three dimensions and two dimensions, here we have some advantages like, the pressure is no directly coming the expression the equations are in terms of velocity and the vorticity. Wherever the vorticity time is important then if you use this equation, this form of the navier-stocks equations it will be much easier here generally for this formulation velocity vorticity formulations the boundary conditions will be in terms of the velocity.

Once we solve the vorticity transport and the poiseuille equation, corresponding to this equation b, if you solve this equation we get velocity distribution and the vorticity distribution throughout the domain. Once we get the velocity and vorticity then we can find out other parameters like pressure, we can find out from the obtained values of the velocity and vorticity problems. The velocity vorticity formulation is also used in many problems wherever we can express, we can use the parameter vorticity and further these equations are much easier to solve compare to the primitive variables formulation which we have seen earlier.

That is why, wherever possible we proper to use the velocity vorticity formulation of the navier-stocks equations. In the third formulation is vorticity stream function formulation depending upon the problem, wherever we can write we can express the stream function for the typical problem where we can express the stream function then we use this formulation vorticity stream function formulation.

(Refer Slide Time: 46:38)

Vorticity - Stream function Formulation

$$\nabla^2 \omega = R_e \left(\frac{\partial \omega}{\partial t} + \frac{\partial}{\partial x} \left(\frac{\partial \psi}{\partial y} \omega \right) - \frac{\partial}{\partial y} \left(\frac{\partial \psi}{\partial x} \omega \right) \right) \quad (a)$$

$$\nabla^2 \psi + \omega = \frac{\partial \psi}{\partial t} \quad (b)$$

- B.C.'s: $\psi = \psi_v$ on Γ and,
- $\frac{\partial \psi}{\partial n} = \left(\frac{\partial \psi}{\partial n} \right)_v$ on Γ

If we consider, for example two-dimensional problem here we have two equations, the first equation is written like this same del square omega is equal to R_e into del omega by del t plus del by del x plus del psi by del y into omega minus del by del y del psi del x into omega. This is first equation. Second equation is del square psi plus omega is equal to del psi by del t, here we have a two expressions, first one is equation a del square omega is equal to R_e into del omega by del t plus del by del x del psi by del y of omega minus del by del y of del psi by del x omega and second equation is e 1 as del square psi plus omega is equal to del psi by del t.

Here the boundary condition are in terms of psi, psi is equal to psi v on gamma of the boundary, normal derivative del psi by del n is equal to del psi by del n at d these are the boundary conditions and the equations a and b which is in terms of the Reynolds number R_e and the omega and the psi.

We can solve these two equations, we get the distribution of the stream function and the what is it omega, depending upon the problem this formulation also, we can get a solution and finally once we get the omega and the psi that means, the vorticity and the stream function then, we can get other parameters like velocity and the pressure. Typically, same depending upon the problem, we can solve the problem it very much

easier to use the primitive variable formulations. Some other case the velocity vorticity formulation will be easier and in other case depending upon the problem, we can utilize the vorticity stream function formulation. Depending on the problem we have to choose the formulation then Navier-Stokes formulation, we have to try to solve the problem once the variables whether the primitive variable formulation, directly we get the pressure velocity but in the velocity vorticity formulation we get in terms of the velocity and vorticity.

Then we may have to find out the pressure, the third formulation we get in terms of vorticity in stream function after getting the vorticity stream function, we may have to find out the velocity and the pressure distribution for the problem consider. Depending upon the problem, we can choose the particular formulation try to solve the problem, we have seen the Navier-Stokes equations derivation the various analytical solutions for the simplified cases and also we have seen three kinds of formulations for the Navier-Stokes equations. As we have already discussed the Navier-Stokes equations for the real fluid problem is very difficult to get the exact solution we may have to go for the numerical solutions.
