

**Geosynthetics Testing Laboratory**  
**Prof. Jnanendra Nath Mandal**  
**Department of Civil Engineering**  
**Indian Institute of Technology, Bombay**

**Lecture – 13**  
**Sewn Seam Strength, Permittivity and Transmittivity**

I am Professor J. N. Mandal Department of Civil Engineering IIT Bombay. I will teach you today about the Sewn Seam Strength of the Geotextile Material, because sometimes you required to connect one geotextile with the another geotextile you require sometimes teaching, you require sometime seaming, you require sometime (Refer Time: 00:44) of the Geosynthetics material.

So, this is very important, because this is the joining between the two different types of the either woven or non-woven geotextile or it may be the geogrid material. Therefore, one should know the sewn seam strength of geotextile. Now, seam strength of geotextile this as for as for the specification ASTM D 4884 and International Standard Organization ISO 13426.

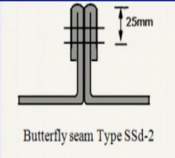

(Refer Slide Time: 01:22)

**Geosynthetics Testing in Civil Engineering**

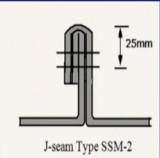

Sewn seam strength of geotextile (ASTM D4884 and ISO 13426)

**Aim and objective:**  
To determine sewn seam strength of a geosynthetic.

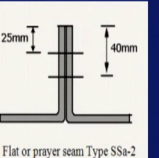

**Introduction:**  
➤ The maximum resistance of junction formed due to joining of two geosynthetics is called sewn seam strength.

Butterfly seam Type SSd-2

J-seam Type SSM-2

Flat or prayer seam Type SSa-2

NPTEL Prof. J. N. Mandal, Department of Civil Engineering, IIT Bombay 73

The main objective of this test: to determine the sewn seam strength of the geosynthetics material. So, maximum resistance of the junction formed due to the joining of two geosynthetics is called the sewn seam strength. We can see here different types of the difference types of the joining system and this is the butterfly seam type that is SSd-2.

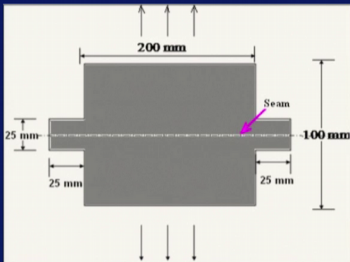

And it is like one geosynthetic material here, another geosynthetic material here, and then you are teaching the spacing of 25 millimeter and this is called butterfly seam. This is another kind of the joining, which you call J Type of seaming. So, this is J-seam type SSM-2 and this spacing between the 2 joining is about 25 millimeter. And, this is another type of joining, which is called flat or prayer seam type of this is SS a-2 so, here also this 25 and 45 millimeter. So, when I will recommend that butterfly of the system is recommended for the joining.

(Refer Slide Time: 03:03)

**Geosynthetics Testing in Civil Engineering**

**Equipment and Accessories required:**

- Tensile testing machine (strain rate =  $10 \pm 3\%$ )
- Clamps

NPTEL Prof. J. N. Mandal, Department of Civil Engineering, IIT Bombay 74

Now, this test is performed the same that in universal testing machine and strain rate about 10 to 3 percent, it is the same as we perform the tensile strength of the geosynthetic material and clamp arrangement is the same. The slightly defines in the sample size as you know, in case of tensile strength of the geosynthetics the size is about 100 millimeter by the 200 millimeter, but in this case these two geosynthetic material is teaching here. So, it is seaming here it is. So, it is about 25 millimeter and 25 millimeter projected and this is the teaching, and then you perform the tensile strength of the geosynthetics material.

(Refer Slide Time: 03:54)

**Geosynthetics Testing in Civil Engineering**

**Procedure:**

- Mount the specimen centrally in the camps.
- Start the tensile testing machine and area measuring device.
- Strain rate =  $10 \pm 3$  %/ min, Unit in kN/m
- Tensile strength is directly measured from instrument as maximum force per unit width to cause rupture.
- Butterfly seam is recommended for sewing

75

Prof. J. N. Mandal, Department of Civil Engineering, IIT Bombay

So, procedure mount the specimen centrally in the camp start the tensile testing machine and the area measuring device. And, as I said the strain rate is 10 plus minus 3 percentage per minute and the unit of the seam strength is in terms of the kilo Newton per meter. So, tensile strength is directly measured from the instrument, as maximum force per unit with to cause the rapture. It also told that butterfly seam is recommended for the same.

(Refer Slide Time: 04:29)

**Geosynthetics Testing in Civil Engineering**

**Calculations:**

- The seam strength efficiency can be expressed as,

$$S_E = (T_{\text{seam}} / T_g) \times 100 \%$$

Where,

T<sub>seam</sub> = wide width seam strength (ASTM D 4884),

T<sub>g</sub> = tensile strength without seam

76

Prof. J. N. Mandal, Department of Civil Engineering, IIT Bombay

So, how to calculate the seam strength? So, seam strength can be calculated and seam strength efficiency can be expressed as  $S_E$  is equal to  $T_{seam}$  divided by  $T_g$  into 100 where  $T_{seam}$  is the wide width seam strength as for ASTM D 4884.

And,  $T_g$  is called tensile strength without change. So, one is without strain, another is with strain. So, you take the ratio of  $T_{seam}$  and the  $T_g$  into 100 and which will give you what will be the efficiency of the geosynthetics material? And, this seam strength we have to take into consideration into the design.

(Refer Slide Time: 05:10)

The slide is titled "Geosynthetics Testing in Civil Engineering" and contains the following text:

Specimen calculations for wide width tensile test:

- Type of geosynthetic: Geomembrane
- Type of seam: fusion
- Tensile strength without seam: 39.4 kN/m
- Seam strength, = 35.4 kN/m

Seam efficiency,  $S_E = (T_{seam} / T_g) \times 100 \%$   
 $= (35.4/39.4) \times 100 \%$   
 $= 89.84\%$

NPTEL logo is visible in the bottom left corner. The footer text reads "Prof. J. N. Mandal, Department of Civil Engineering, IIT Bombay" and the slide number "77" is in the bottom right corner.

Now, specimen calculation for the wide width tensile strength let us test type of the material it may be geosynthetics or the geomembrane material. And type of the second sewn seam is may be the fusion, or tensile strength without seam is 39.4 kilo Newton per meter and which seam strength is 35.4 kilo Newton per meter.

So, you can determine what is the seam efficiency? So, seam efficiency  $S_E$  is equal to  $T_{seam}$  divided by  $T_g$  into 100; that means, 35.4 divided by 39.4 into 100. So, this efficiency is 89.84 percentage. So, this one should understand that, what will be the seam strength of the geosynthetics, because this is one of the weakest point of the geosynthetics material.

And, that you have to consider into the design otherwise sometimes that infrastructure or any kind of the design, there will be a possibility for the failure of the geosynthetic material.

(Refer Slide Time: 06:26)

The slide is titled "Geosynthetic Testing in Civil Engineering" in orange text on a dark blue background. Below the title, the text "Hydraulic properties:" is written in green. A list of five properties follows, each preceded by a yellow arrowhead: Porosity, Apparent opening size, Percent open area, Permittivity or cross plane permeability, and Transmissivity or In-plane permeability. In the bottom left corner, there is a circular NPTEL logo. In the bottom center, the text reads "Prof. J. N. Mandal, Department of Civil Engineering, IIT Bombay". In the bottom right corner, the number "78" is displayed.

Next, I will discuss the hydraulic property. So, so far what we have discussed this is all strength provided problem? What we use the geosynthetic material for the design of the of the reinforce soil retaining wall or the slope related problem or payment related problem. Now, we will discuss the another property. So, it is hydraulics property. It is very important and hydraulic property is related with the flow related problem.

It maybe flow of liquid or water or the gas. So, this is also very important, it should be related with also the drainage and also the filtration system. So, this hydraulic property, we have to determine what will be the porosity of the geosynthetic? What will be the apparent opening size or the equivalent opening size of the geosynthetic material, percentage open area and the permittivity of the geosynthetic material and transmittivity of the geosynthetic materials?

These are the two parameter is very important particular is the permittivity and transmittivity and also the equally important that, what will be the apparent opening size or equivalent opening size of the geosynthetic material. So, I will just proceed one by one how you will perform all the kind of the testing that is.

(Refer Slide Time: 07:59)

**Geosynthetics Testing in Civil Engineering**

**Permittivity or cross plane permeability (ASTM D4491 and ISO 11058):**

**Aim and objective:**  
To determine permittivity of a geosynthetic.

**Introduction:**

- Permittivity of a geotextile is defined as the discharge of water per unit cross sectional area per unit head under laminar flow condition.
- Main function of geosynthetic is filtration when water flows perpendicular to the geosynthetic.
- The permittivity of geotextile can be determined by:
  - Constant head test
  - Falling head test

 NPTEL

Prof. J. N. Mandal, Department of Civil Engineering, IIT Bombay

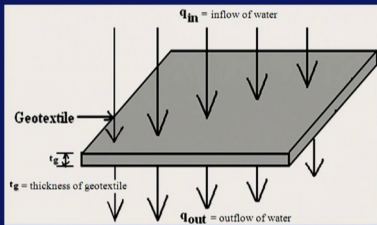

79

First that permittivity of cross plane permeability and this test is performed as for ASTM D 4491 and ISO 11058, the main objective of this test to determine the permittivity of a geosynthetic material. Now, what do you mean by the permittivity? So, permittivity of the geosynthetic is defined as the discharge of the water per unit cross section area per unit head under the laminar flow condition. And, main function of the geosynthetic is the filtration, when the water flow perpendicular to the geosynthetic material not across the geosynthetic material.

So, you remember that when you talk about the permittivity then water flowing across the plane of the geosynthetic material. So, that what you call the permittivity. And, you have to determine whether it is a permittivity or the transmittivity, whether it is a filtration or the drainage you have to decide, when you have to apply accordingly to your particular problem or particular application. Now, this test is performed with the constant head test or the falling head test method. So, I will show you what is the constant head method and the falling head test method?

(Refer Slide Time: 09:40)

**Geosynthetics Testing in Civil Engineering**

From Darcy's equation:

$$q = k_n \cdot i \cdot A_g = k_n \cdot \frac{\Delta h}{t_g} \cdot A_g$$

$$\frac{k_n}{t_g} = \frac{q}{\Delta h \cdot A_g}$$

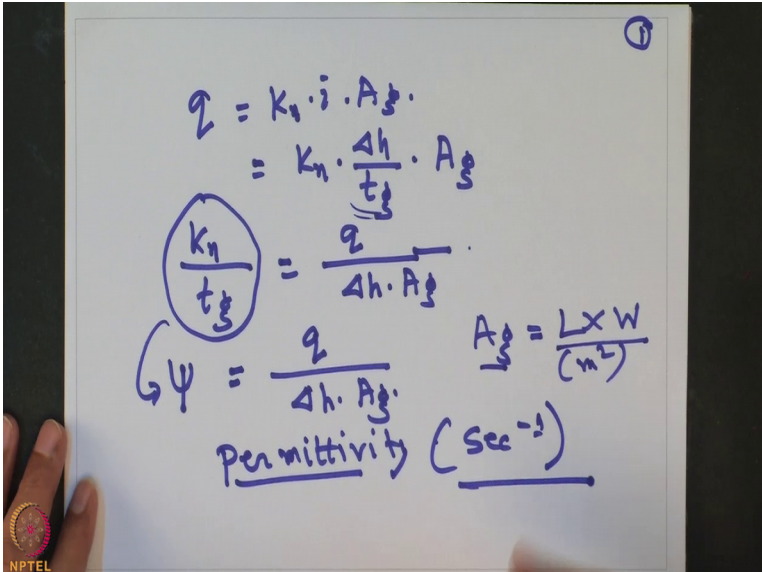

$$\psi = \frac{k_n}{t_g} = \frac{q}{\Delta h \cdot A_g}$$

$\psi$  = Permittivity ( $\text{sec}^{-1}$ )  
 $q$  = Flow rate ( $\text{m}^3/\text{sec}$ ),  
 $K_n$  = Hydraulic conductivity (Normal to geosynthetic) ( $\text{m/s}$ ),  
 $A_g$  = Area of geosynthetic =  $L \times W$  ( $\text{m}^2$ ),  
 $\Delta h$  = Head lost ( $\text{m}$ ), and  
 $t_g$  = Thickness of geosynthetic ( $\text{m}$ ).

Prof. J. N. Mandal, Department of Civil Engineering, IIT Bombay

So, here you can see that this is the geosynthetics material and the water is flowing from the top to the bottom this is  $q$  in and this is  $q$  out, and this is the geotextile material, and this geotextile material has a thickness that is  $t$  of  $t$  of  $g$ . And, this is the thickness of geosynthetic material and water is flowing across the plane of the geosynthetics. So, you know that from the permittivity of the geosynthetic material from the Darcy's equation, we can I can write that from that Darcy's equation that is you know  $q$  is equal to  $k$  into  $n$  into  $i$  into  $A$  into  $g$ .

(Refer Slide Time: 10:29)

$$q = k_n \cdot i \cdot A_g$$

$$= k_n \cdot \frac{\Delta h}{t_g} \cdot A_g$$

$$\frac{k_n}{t_g} = \frac{q}{\Delta h \cdot A_g}$$

$$\psi = \frac{q}{\Delta h \cdot A_g}$$

Permittivity ( $\text{sec}^{-1}$ )

$A_g = \frac{L \times W}{(\text{m}^2)}$

So, this again is equal to  $k$  into  $n$  is equal to  $\Delta h$  and  $t_g$  is the thickness of the geosynthetic material and  $A$  is equal to area of geosynthetic. So, you can write  $k$  of  $n$  divided by  $t_g$  is equal to  $q$  divided by  $\Delta h$  into  $A$  of  $g$ . So, this is the  $\psi$   $\psi$  the permittivity. So, this you can say this part is the  $\psi$   $\psi$ , which is permittivity will be equal to  $q$  divided by  $\Delta h$  into  $A$  of  $g$ . So,  $\psi$  which you call the permittivity and this unit is per second, remember this units of permittivity is per second ok.

$q$  is the  $48$  is meter cube per second and  $k$   $n$  is the hydraulic conductivity, that is the normal to the geosynthetic, that is unit is meter per second and the  $\Delta h$  is equal to head loss and  $t_g$  is the thickness of geosynthetic material and  $A$  of  $g$ . The  $A$  of  $g$  is area of geosynthetic material, which you can say that  $L$  into  $W$  that is  $m$  meter square. So, do you know what will be the length of the geosynthetic material? And, what will be the width of the geosynthetic material?

So, knowing this value of quantity of flow water percentage geosynthetic  $I$  and the head loss and the area of the geosynthetic that is length into the width so, you can determine: what is the permittivity. And, permittivity unit of permittivity can be expressed as meter per second per second only.

(Refer Slide Time: 12:50)

Now, this another also kind of the different hydraulic gradient, you can write that different hydraulic gradient of the hydraulic gradient the flow rate of  $q$  will be the

different; the slope of the  $q$  by  $A g$ , but says this is slope this is a slope of  $q$  by this is the this is the slope different hydraulic gradient you are taking.

(Refer Slide Time: 13:24)

**Geosynthetics Testing in Civil Engineering**

**Procedure:**

**Constant head test**

- The apparatus is assembled and the specimen is clamped.
- Fill the apparatus with water until water overflow.
- Adjust the discharge to obtain a head of 50 mm.
- The test is performed under this head.
- Record the quantity of water collected from discharge pipe for certain time interval.
- Repeat the test at different head.
- Permittivity is recorded as average value from all the tests.

Prof. J. N. Mandal, Department of Civil Engineering, IIT Bombay 84

And, this is the this is the different hydraulic gradient of flow rate that is  $q$  will be the different types the slope of  $q$  by  $A$  of  $g$  versus  $\Delta h$  curve, at the origin which will give you that what will be the permittivity of the geosynthetics material?

(Refer Slide Time: 13:59)

**Geosynthetics Testing in Civil Engineering**

**Equipment and Accessories required:**

- Stand pipe
- Geosynthetic clamping device
- Discharge pipe
- Reservoir

**constant head permittivity test**

Prof. J. N. Mandal, Department of Civil Engineering, IIT Bombay 82

Now, what are the equipment you required for the determination of constant head permeability test of the geosynthetics material. So, you required that what is the stand

pipe? And geosynthetics is clamped geosynthetics is clamped here and the device and discharge pipe and then it is the reservoir. So, water can flow from top to the bottom at a constant head of permittivity. And, then you are collecting the water here in the reservoir.

(Refer Slide Time: 14:49)

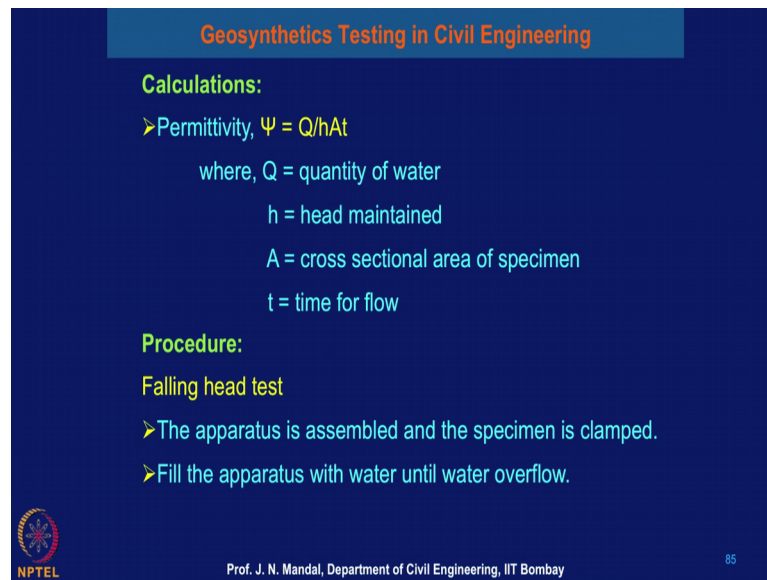

So, after collecting the reservoir, it is another kind of falling head permeability test method this is a geosynthetics material is here. And, this distance is the initial time initial time  $t_0$ , when the height is initial  $h_i$ . And when the, this is the time after a certain time this time is  $t_f$  final time. So, then this is the  $h_f$  height, which is measuring from here to here and geotextile material is here. So, this is the stand pipe. So, form this test. So, you can determine that what will be the permittivity of the geosynthetics material?

Now, this procedure for constant head test the apparatus is assemble and specimen is clamped fill the apparatus with water until water overflow. Adjust the discharge to obtain the, to obtain a head of about 50 millimeter. So, the test is performed under this head and records the quantity of water collected from the discharge pipe for a certain time interval and repeat the test as different head, so permittivity is recorded as the average value from all the test.

(Refer Slide Time: 16:22)

**Geosynthetics Testing in Civil Engineering**

**Calculations:**

- Permittivity,  $\Psi = Q/hAt$

where, Q = quantity of water  
h = head maintained  
A = cross sectional area of specimen  
t = time for flow

**Procedure:**

**Falling head test**

- The apparatus is assembled and the specimen is clamped.
- Fill the apparatus with water until water overflow.

NPTEL Prof. J. N. Mandal, Department of Civil Engineering, IIT Bombay 85

So, we can calculate the permittivity you know the equation  $\Psi$  is equal to  $Q$  by  $h$  into  $A$   $t$ . So, where  $Q$  is equal to quantity of water,  $h$  is equal to head maintained,  $A$  is equal to cross selection area of the specimen and  $t$  is the time of flow. So, another so, knowing this value what will be quantity of water you have collected at a particular time.

So, what will be the height? You know what a head? And, you know the cross sectional area of the geosynthetic material. So, you can determine the permittivity using this equation. Now, another procedure is the falling head test method. This apparatus is assemble and the specimen is clamped and fill the apparatus with water until the water overflow.

(Refer Slide Time: 17:15)

**Geosynthetics Testing in Civil Engineering**

- Adjust a water level in stand pipe.
- Start the stop watch and note down the time for a fall of 20 mm in level of water in stand pipe.
- Record minimum 5 readings.

**Calculations:**

- Permittivity,  $\Psi = 2.3 \frac{a}{A_g \Delta t} \log_{10} \left( \frac{h_i}{h_f} \right)$

$\Psi$  = permittivity (sec<sup>-1</sup>)  
 $a$  = Area of stand pipe (m<sup>2</sup>)  
 $A_g$  = Area of geosynthetics (m<sup>2</sup>)  
 $h_i$  = Initial head at time  $t_0$ ,  
 $h_f$  = Final head at time  $t_f$ , and  
 $\Delta t = t_f - t_0$  = Change in time (sec)

86

Prof. J. N. Mandal, Department of Civil Engineering, IIT Bombay

So, adjust a water level in the stand pipe and then we can start the stopwatch and note the time for a fall of about 20 millimeter in the level of the water in the stand pipe. So, we record the minimum 5 reading.

(Refer Slide Time: 17:54)

$$\Psi = 2.3 \frac{a}{A_g \Delta t} \log_{10} \left( \frac{h_i}{h_f} \right)$$

Permittivity (sec<sup>-1</sup>)

$a$  = Area of Stand pipe (m<sup>2</sup>)  
 $A_g$  = Area of GS material (m<sup>2</sup>)  
 $h_i$  = Initial head at time  $t_0$ .  
 $h_f$  = Final head at time  $t_f$  and  
 $\Delta t = t_f - t_0$  = change in time (sec)

So, you can use this equation that is equal to psi which you call the permittivity. So, equation you know psi is equal to 2.3 into a divided by A of g into delta of t into log of 10 h of i by h of f. So, you know this i pi, which you call the permittivity. And the unit is per second per seconds. And a small a is equal to area of stand pipe, you know area of

that is stand pipe that is let us say meter square. And  $A_g$  is you know area of geosynthetics material area of geosynthetics material. And, this is in meter square and  $h_i$  is equal to initial head initial head at time  $t_0$  and  $h_f$  is equal to final head at time  $t_f$ .

And,  $\Delta t$  is equal to that is  $t_f - t_0$  that is change in time change in time and that it is which unit is second. So, knowing this all these value you know cross sectional area of the stand pipe, you know what will be the  $h_i$  value and the  $h_f$  value and you know the, what will be the  $\Delta t$  value, you know what will be the area of the geosynthetics material? So, you can calculate the permittivity of the geosynthetics material.

(Refer Slide Time: 20:17)

**Geosynthetics Testing in Civil Engineering**

Specimen calculation to determine permittivity of a specimen using constant head method:

- Type of geosynthetic: Non woven geosynthetic
- Quantity of water collected = 204.95 mm<sup>3</sup>/ sec
- Head maintained = 50 mm
- Cross sectional area of the sample = 2.827 mm<sup>2</sup>
- Permittivity =  $Q/(\Delta h \times A)$   
=  $204.95/(50 \times 2.827)$   
= 1.44 sec<sup>-1</sup>

NPTEL Prof. J. N. Mandal, Department of Civil Engineering, IIT Bombay 87

So, specimen calculation for the to determine the permittivity of a specimen. For example, you are taking that type of geosynthetics is the non-woven geosynthetics material and quantity of water collected about 204.95 millimeter cube per second. And, the head maintenance about 50 millimeter and cross section area of the sample is given 2.827 millimeter square. So, you know the equation permittivity is equal to  $Q$  by  $\Delta h$  into  $A$ . So,  $Q$  is the quantity of water collected that is 204.95.

This divided by that is  $\Delta h$ ; that means, head measurement is 50 and this into this is cross sectional area of the sample this is 2.827. So, if you can calculate. So, you can obtain the permittivity which is 1.44 per second. So, this is what we call the permittivity

of the geosynthetics material? The permittivity of the geosynthetics material is very important and particularly in case of the drainage and the filtration problem. And you remember permittivity, then when the water or gas pass across the plane of the geosynthetics material and the unit of permittivity is per second. Now, we will discuss about the transmittivity of the geosynthetics material. Now, transmittivity it is a in plane, then when the water or liquid or gas pass along the plane of the geosynthetics material is called the transmittivity.

(Refer Slide Time: 22:20)

**Geosynthetics Testing in Civil Engineering**

**Transmissivity or in - plane permeability (ASTM D4716 and ISO 12958):**

**Aim and objective:**  
To determine transmissivity of a geosynthetic.

**Introduction:**

- Transmissivity of a geotextile is defined as the discharge of water per unit width per unit gradient in the direction parallel to the plane of specimen.
- Major function of geosynthetic is drainage when water flows along the plane of geosynthetic under applied load.

 Prof. J. N. Mandal, Department of Civil Engineering, IIT Bombay 88

So, this transmittivity can be can be can be done by the ASTM D 4716 and ISO 12958. So, main objective of this test to determine transmittivity of a geosynthetics material, to transmittivity of the geotextile is defined as the discharge of water per unit width per unit gradient in the direction of parallel to the plane of the specimen. So, manual function of the geosynthetics is the drainage when the water flow along the plane of the geosynthetics material. So you remember between the define between the two, one is the relation another is the drainage.

(Refer Slide Time: 23:17)

**Geosynthetics Testing in Civil Engineering**

At different hydraulic gradients, the flow rate (q) will be different. The slope of  $q/w_g$  vs.  $i$  curve at the origin gives the permittivity.

**Transmissivity test**

- Full length in-plane flow
- Radial in-plane flow

Prof. J. N. Mandal, Department of Civil Engineering, IIT Bombay

In case of the permittivity, it is a filtration and in case of the transmissivity it is a drainage; that means, when the water flow along the plane of the geosynthetic material.

(Refer Slide Time: 23:35)

**Geosynthetics Testing in Civil Engineering**

From Darcy's equation, we can derive the expression for transmissivity,

$$q = k_p \cdot i \cdot A_g = k_p \cdot i \cdot (w_g \cdot t_g)$$

$$k_p \cdot t_g = \frac{q}{w_g \cdot i}$$

Transmissivity ( $\theta$ ) =  $k_p \cdot t_g = \frac{q}{w_g \cdot i}$

$\theta$  = transmissivity of geosynthetic ( $m^2/sec$ )  
 $q$  = flow rate ( $m^3/sec$ ),  
 $k_p$  = hydraulic conductivity (in-plane of geosynthetic) ( $m/sec$ ),  
 $i$  = hydraulic gradient =  $(\Delta h/L_g)$ ,  
 $\Delta h$  = head loss ( $m$ ),  
 $L_g$  = length of geosynthetics ( $m$ ), and  
 $w_g$  = width of geosynthetics ( $m$ )  
 $t_g$  = thickness of geosynthetic ( $m$ )

Prof. J. N. Mandal, Department of Civil Engineering, IIT Bombay

So, how to that calculate that transmissivity?

(Refer Slide Time: 23:48)

Handwritten equations on a whiteboard:

$$q = k_p \cdot i \cdot A_g$$

$$= k_p \cdot i \cdot (W_g \times t_g)$$

$$k_p \times t_g = \frac{q}{W_g \times i}$$

↳ Transmissivity ( $\theta$ ) =  $\frac{m^2}{sec.}$

$$i = \frac{\Delta h}{L_g}$$

The diagram shows a rectangular cross-section of a geosynthetic material with width  $W_g$  and thickness  $t_g$ . A hydraulic gradient  $i$  is indicated by a downward arrow on the right side. The discharge  $q$  is shown as a horizontal arrow pointing to the right through the material.

So, from the Darcy's equation you know  $q$  is equal to  $k$  of  $p$  into  $i$  into  $A$  of  $g$ . So, this is  $k$  of  $p$  into  $i$  into here area is equal to  $W$  of  $g$  into  $t$  of  $g$ . So, we can write  $k$   $p$  into  $t$  of  $g$  is equal to  $q$  divided by  $W$  of  $g$  this into  $i$  or  $k$   $p$  by  $t$   $g$  which you call the transmissivity. And, this is express as  $\theta$  and this is transmittivity, this unit is meter square per second. So, here because water is flowing along the plane of the geosynthetic material that is why this if the geosynthetic material is like this and water is flowing along the plane of the geosynthetic material.

So, this geosynthetic material has a certain thickness that is  $t$  of  $g$  and this width is equal to this  $W$   $g$  width of the (Refer Time: 25:18) that is why this area because this is flowing along the plane of geosynthetic material. So, that area of geosynthetic will be  $W$   $g$  into  $t$  of  $g$ . So, when you know that  $\theta$  transmittivity of the geosynthetic material, the unit is meter square per meter square meter square per second and  $q$  is the product that is meter cube per second, and  $k$   $p$  is the hydraulic conductivity in plane of the geosynthetic material. And  $i$  is equal to hydraulic gradient that  $i$  is equal to hydraulic gradient is equal to  $\Delta h$  by  $L$  of  $g$  and  $\Delta h$  is the what you call head loss?

And,  $L$   $g$  you know length of the geosynthetic material, if this is the length of the geosynthetic material here. And  $W$   $g$  is the width of the geosynthetic material and  $t$   $g$  is the thickness. So, you know all this value. So, you can determine what will be the hydraulic conductivity or the transmittivity of the geosynthetic material? Now from this

you can have different types of the hydraulic gradient you can take and the flow rate  $q$  will be the different slope of the  $q$  by  $Wg$  versus the  $i$  curve at the origin give the permittivity. So, there are different types of the test one is the full length in plane flow, another is radial in plane flow.

(Refer Slide Time: 27:04)

**Geosynthetics Testing in Civil Engineering**

**Equipment and Accessories required:**

- Metal base
- Reservoir
- Loading mechanism
- Outflow weir
- Manometer

Prof. J. N. Mandal, Department of Civil Engineering, IIT Bombay

So, full length in plane flow is required the accessories that what will be the metal base; what will be the reservoir? What will be the loading mechanism? And outflow weir and the manometer. So, here you can see that this is the equipment and this is the geosynthetics material, which is located between the 2 solid plate and the water reservoir is here water is flowing across the plane of the geosynthetics material and you are collecting the water here in a in a in a container.

And, then you will be knowing what is the quantity of water passes along the plane of the geosynthetics material and collect it into this water (Refer Time: 27:57). And, at a particular time what will be the volume of water collected here. And they defines in the head is equal to delta of  $h$ . So, this is you have to perform the test under different loading, it may be the 50 kilonewton 250 100 kilonewton 250 kilonewton or the 300 or 350 kilonewton or 400 or 500 600 700 800. And, then you can correlate between the what should be the quantity of water pluses and what should be the load?

So, you can draw a relationship between the quantity of water flow and then what should be the applied load? So, you know each and every time what will be the quantity

of water flow and what will be the under water pressure? So, you can make a correlation between the between the applied load and corresponding the quantity of water, you can have a nature of that curve the quantity of flow is load is increasing the your quantity of water flow is decreasing. So, this is very important when you will use that PPD or prefabricated particle drain for a particular project, this is very important what quantity of water should flows through the geosynthetics material.

Thank you.
