Energy and Momentum Principle
Lecture No. # 02
Computation of Critical Depth

Friends, today we shall be discussing about computation of critical depth. We have already discussed regarding how to compute normal depth and also we have discussed about the concept of specific energy. Today, we shall be going to see, how we can calculate or how we can compute the critical depth, and how these things are coming into use in our different hydraulics calculations. Well, before going to this, let me just recapitulate what we did in the last class.

Well, we started with concept of specific energy. That means, just to recall, that specific energy is nothing but energy per unit weight of flowing fluid, rather per unit weight of flowing fluid with respect to channel bed. So, this is what we call as specific energy. Then, we did discuss about the specific energy diagram. Well, this specific energy is a function of the depth. So, if we plot the depth and the specific energy that diagram basically we call as specific energy diagram.

Well, then we did discuss about another diagram that we call as a depth discharge diagram. Well, for a given specific energy, we can have a relationship between the discharge and the depth. So, that diagram, that is, for a constant specific energy, we get a single line for depth and discharge a curve, we get rather and then again for a different energy level, we get different lines, a set of curve we get that we call as a depth discharge diagram.

(Refer Slide Time: 01:38)

Well, then again we did discuss about critical depth, which is very important. Today, we are going to discuss about the computation of critical depth. So, critical depth is the depth which corresponds to the minimum specific energy. So, we got specific energy and then, we could see that for a particular depth of flow, for a given discharge, the specific energy in a channel become minimum. That particular depth is called a critical depth. Well, then we got another term that is called alternate depth. That also, we did discuss.

What you mean by alternate depth that for a particular specific energy. That means, in a channel, we can get a specific energy for two different depths. We can have same specific energy and these two different depths are called alternate depth. I mean, one of these two depth is in the super-critical region and another, is in the sub-critical region. So, when the flow is in sub-critical condition, then for a particular depth, suppose we are getting a specific energy. Then, say for the same specific energy, we can get another depth when the flow is in a super-critical region. So, that way these depths are called alternative. So, that also we did discuss in our last class.

Then, we talked about another term that is called critical slope. Well, when a channel is carrying a particular discharge Q , then for a particular slope, we can have uniform flow for a particular slope. We can have uniform flow at critical depth; we know that critical depth is already defined. So, we know that this is that critical depth and in a channel for a particular slope, we can adjust the slope. We can have a slope where we are having

uniform flow for a particular discharge and that uniform flow depth, is equal to the critical depth. So, that particular slope we refer as critical slope. That means, critical slope is the slope where uniform flow occur with critical depth. Well, now when the slope of channel is flatter, then the critical slope, we call this as mild slope. When the slope of the channel is steeper, then the critical slope, we call that as a steep slope. So, that way we got critical slope, we got mild slope, then we got steep slope.

Well, after that, we did discuss the condition of critical flow. That means how we will understand that flow is critical. Well, we can define the minimum specific energy, means it is critical flow, but how we will understand. So, we need some definite index to show that it is the critical flow condition. Basically, one condition is definitely that when specific energy is minimum for a given discharge. That is called critical flow condition. Then, another condition is that the when Froude number, suppose in a channel, we are observing the velocity, we are observing the depth and then we can very easily calculate the Froude number. That we all know what is Froude number.

So, when that Froude number is unity, then we call, that is the critical flow condition, that we did derive in the last class. Similarly, we could see another point also for a given specific energy discharge is maximum at critical flow condition. So, that is also another condition. Then, we got another point related to that kinetic energy is half of the hydraulic depth. So, that sort of relation also, we did obtain and then we got another point, that is, of course, we did not discuss in detail that point, but still we just marked that point. That is specific force. Of course, specific force is minimum at critical flow condition. So, all those different conditions, we got for critical flow condition and which indicate that the flow is critical.

Now, after that we came to computation of critical depth rather computation of critical flow, means computation of critical depth. So, we started with that. We rather end up our last class with that computation of critical flow. There we could see that for a trapezoidal channel, if our channel is of trapezoidal shape, then we could see that we get relations which do not permit us to calculate the critical depth directly or explicitly. We can calculate and in that case, we need to go for trial and error procedure. So, let us start from that particular point, that is, computation of critical depth. So, you can concentrate into the slide.

(Refer Slide Time: 08:54)

Computation of Critical depth

- Trapezoidal $\frac{Q^2 T}{g A^3} = 1$ $\frac{Q^2 (B + 2zy_c) = [(B + zy_c) y_c]^3}{g}$ 
- Trial and error,
- Graphical procedure
- Section factor for critical depth computation

$$\frac{Q^2 T}{g A^3} = 1$$

$$\Rightarrow \frac{Q^2}{g} = A^3 \left(\frac{1}{T} \right) = A^3 D$$

$$\Rightarrow \frac{Q^2}{\sqrt{g}} = \frac{A^3 D}{\sqrt{g}} = Z$$
- Hydraulic Exponent (M) $Z^3 = C_1 D^3$

When it is trapezoidal channel, then we know that very basic relation for critical depth is $Q^2 T$ by gA^3 . This is equal to 1 that we did derive in the last class. If it is a trapezoidal channel like this, then we get that $Q^2 T$, that is, the top width T . If the side slope is z , then the top width T is B . That means the bottom with B plus twice of ZY_c c twice of ZY_c . So, this part and that way, we are getting this $Q^2 T$ by g and A^3 . If we write on this side, then area is B plus ZY_c into Y_c cube, so A^3 . So, that is what we are getting and from this equation, it is clear that we cannot have this in the form that Y_c is equal to some other known term. So, we cannot calculate it directly.

Well, what we can do then for this sort of trapezoidal channel? We need to go for trial and error procedure. We put some critical depth value and we try to see whether the left hand side and right side is matching or not. Then, if we keep on changing this one and we try to get the value of Y_c by trial and error procedure, well that procedure is definitely tiresome and time consuming. Of course, now with the advent of computer, we can get it very easily, but otherwise, if we go for hand calculation, this is really problematic. That is why some graphical procedures were also developed.

So, we have some graphical procedure and then in the graphical procedure, we use a term that is called section factor. In the computation of normal depth also, we got a term called section factor, which is basically coming from the sectional dimension of the flow section. Here, this section factor also we use, but this section factor for critical depth

computation is not the same expression, that we got for normal depth. It is different expression. So, if we start from this relation $Q^2 T / Z A^3 = 1$, then we can write it that $Q^2 / Z = A^3 / T$. So, that is given us. We know that A / T is nothing, but hydraulic depth D . So, as A / T is equal to hydraulic depth D .

So, we can have, that is equal to A^2 , that is area square into hydraulic depth. That we can write as $Q / \sqrt{g}$ taking, I mean square root of both side, we can write as $Q / \sqrt{g} = A \sqrt{D}$. This particular expression is called section factor Z for critical depth computation using this section factor. In fact, we can find this section factor, if we know the Q and g is, of course, known. So, once Q is given, we can find this value. Then, we have some graphical platform which we could find the critical depth value. However, nowadays these are not used. Utmost, the basic reason is that we have computer. We can go for trial and error method very easily and that is why, these methods are not having that popularity as it had earlier.

So, then similarly from this expression, we can see, we can rewrite this expression. The Z is equal to $A \sqrt{D}$. A is also a function of Y and D hydraulic depth is also a function of Y . So, that way, Z^2 we can write that $A^2 \sqrt{D}$. What we had? So, that we can write as C , I mean 1 co-efficiency, then Y to the power M . This is the depth. So, that way, from this relation, we are writing it in terms of one exponent M . That is called hydraulic exponent M for critical depth computation. Just as an information, I am just sharing these things that this sort of relation are using this hydraulic exponent M , then plotting it. This expression again in graphical form, we could solve for the critical depth, but as I am telling that nowadays, we have other easier procedure. So, we normally, do not go for this sort of graphical procedure.

Well, then from this particular slide, we could see that computation of critical depth, of course, we are talking about the expression what we are getting for trapezoidal channel. For this sort of channel computation of critical depth, we cannot get directly and that is why we are talking about all these graphical procedure or trial and error procedure. Is it the same situation for other shape of channel? That is, if our channel is say rectangular, if our channel is say triangular, then what will happen? So, let us just see, what sort of expression we get for solving critical depth in these different types of channels.

(Refer Slide Time: 14:47)

Computation of Critical depth

- Rectangular Channel

$$\frac{Q^2 T}{g A^3} = 1$$

$$\Rightarrow \frac{Q^2 B}{g B^3 y_c^3} = 1$$

$$\Rightarrow \frac{(Q^2)^{1/3}}{g (B^2)^{1/3} y_c} = 1$$

$$= \frac{q^2}{g} = y_c^3 \Rightarrow y_c = \left(\frac{q^2}{g} \right)^{1/3}$$

First, let us talk about rectangular channel. So, this is a rectangular channel. Then, say this is B bed width. In D, if this depth is y_c , that is the critical depth. Now, starting from the very general relation, $Q^2 T$ by $g A^3$ is equal to say 1. This is a general expression for critical depth. So, we can start from that and here, our top width T is nothing, but equal to the B . So, what we can write that this implies Q^2 . Then, we can write it as B and g and area is nothing, but B into y_c . So, we can write this as B^3 into y_c^3 . This is equal to 1.

So, this area cube and from that we can write it in a different form. So, this B^3 and B is there. So, it can be written Q^2 by B^2 and g , let it remain like that 1 by y_c^3 equal to 1. Now, this Q^2 by B^2 , that term can be written as in the term of unit discharge. So, discharge per unit width, that is Q is the discharge. So, per unit width means Q by B . That can be written as unit discharge and symbol used for, that is small q .

So, this can be written as Q^2 by g and that can be written as equal to y_c^3 . This implies that y_c is equal to Q^2 by g whole to the power 1 third. So, that way for a rectangular channel, we can see that we can calculate the critical depth y_c directly. If we know the Q value, small q or say capital Q and if we know the B value bed width B , then we can directly calculate this critical depth y_c is equal to Q^2 by g whole to the power 1 third.

Well, one important point. Though, it is obvious that we need to mention or rather, if we mention this is better that for a channel, if someone ask that a channel is getting this much of discharge and it is having this much of slope, what is the critical depth. Normally, when someone asks to compute critical depth, many student I have seen that things about the slope here, basically critical depth is not depending on the slope. So, critical depth is a not a function of slope. Rather, we can calculate the critical depth as in terms of Q and this g value. So, that way critical depth can be calculated directly. Well, now let us see another relationship.

(Refer Slide Time: 18:21)

E and Y Relationship for Critical Condition (Rectangular)

• Relationship of critical depth Y_c and Specific Energy

$$E_{min} = Y_c + \frac{V_c^2}{2g}$$

$$= Y_c + \frac{Q^2}{Y_c^3 2g}$$

$$= Y_c + \left(\frac{Q^2}{g}\right) \frac{1}{2 Y_c^3}$$

$$E_{min} = Y_c + \frac{Y_c^3}{2 Y_c^3} = Y_c + \frac{Y_c}{2}$$

$$E_{min} = \frac{3}{2} Y_c$$

$$Y_c = \frac{2}{3} E_{min}$$

Also shown: $V = \frac{Q}{A} = \frac{Q}{b Y_c} = \frac{Q}{b Y_c}$

Another relationship at critical condition, suppose the channel is flowing in a critical, so water is flowing in a channel with critical condition or at a particular section. We have a critical depth. Now, what is the energy at that point? We know that energy or the specific energy is minimum, that is known, but I mean, can we express that energy in terms of that critical depth, because we know that energy is a function of Y, depth Y.

So, at critical condition, can we have a definite relationship between this specific energy and the depth? Well, let us just explore that. So, in this slide, we will be discussing about, that is E versus Y relationship for critical condition and this we are discussing for, say rectangular channel as we are starting with rectangular channel. Well, we know that, that is why, say relationship of critical depth Y_c and specific energy, we are meaning,

but specific energy we can always find as E_{minimum} because this particular condition, we are talking about minimum specific energy because it is the critical flow condition.

Well, so, we can start like say E_{minimum} is equal to Y_c plus v^2 by twice gY_c plus v^2 by twice g as we are writing E_{minimum} . So, we are writing here Y_c . We are writing here, critical depth. Well, then V^2 that we can write as, V is nothing, but equal to Q by area and for rectangular channel this is nothing, but Q by B into Y_c . This is always critical depth. So, this is equal to, we can write as Q by B . That part, we can write as Q by Y_c . So, this part, we can write this is equal to Y_c plus V^2 . We can write as Q^2 by Y_c^3 and then, it is twice g . From this expression, what we can write that Y_c plus, we had one expression Q^2 by g . So, I am keeping it like Q^2 by g .

If we go to our previous slide, we could see that q^2 by g . This expression Q^2 by g is nothing, but Y_c^3 . So, this Q^2 by g , we can write as Y_c^3 . This is plus. So, this is equal to Y_c plus Y_c^3 by $2Y_c^2$ and that will lead us to, say Y_c plus Y_c by 2 Y_c plus Y_c by 2 . All these we are writing about E_{minimum} . So, this is nothing, but we can write that 3 by 2 into Y_c .

So, Y_c minimum, we can write as E_{minimum} is equal to 3 by 2 into Y_c or this can be written in the form that Y_c is equal to 2 by 3 E_{minimum} . So, once we know the energy E_{minimum} , then we can calculate the Y_c directly from this or if we know the Y_c , we can calculate E_{minimum} directly from this. So, this relation shows that, there is a definite relation for critical depth computation or for computation of minimum specific energy in critical condition.

(Refer Slide Time: 23:01)

Computation of Critical depth

- Triangular Channel

$$\frac{Q^3 T}{g A^3} = 1$$

$$\Rightarrow \frac{Q^3 2ZY_c}{g (ZY_c^2)^3} = 1$$

$$\Rightarrow Y_c^5 = \frac{Q^3 2Z}{g^2 Z^3} = \frac{2Q^3}{g^2 Z^2}$$

$$\Rightarrow Y_c = \left(\frac{2Q^3}{g^2 Z^2} \right)^{1/5}$$

$A = \frac{1}{2} 2ZY_c \cdot Y_c$
 $A = ZY_c^2$

Now, let us see if our channel is not rectangular. Rather, say it is a triangular channel. So, let me draw a triangular channel. Suppose, we are having flow Y_c and then, side slope is Z . So, this top width here, it will say this part will be ZY_c . So, total will be twice Z into Y_c and this Z is basically, we are writing about the side slope Z . So, in triangular channel, again if we start from the various basic relation, that is $Q^3 T$ by gA^3 and area we can write as half of base in altitude. So, base of this triangular is twice ZY_c and altitude is equal to Y_c .

So, this is equal to ZY_c^2 square. So, area we can write like that. So, $Q^3 T$ by gA^3 cube equal to 1. That will lead us to Q^3 square, then top width is equal to twice Z into Y_c . Then, it is g and area we can write as ZY_c^2 square whole cube. Now, from this, we can express Y_c in terms of the other value. I mean in terms of the other value. So, let us try doing, that is, will be Y_c^5 equal to $\frac{2Q^3}{g^2 Z^2}$. This part will be and this is $1Y_c^5$. So, ultimately, we can write Y_c^5 equal to $\frac{2Q^3}{g^2 Z^2}$. Then, twice Z and here, it will be g and Z to the power cube.

So, finally, we can have it in the form that Q^3 square, twice Q^3 square by gZ^2 square. So, Y_c^5 we are getting in the form that twice Q^3 square by gZ^2 square. Using this relationship again, say Y_c is equal to $\left(\frac{2Q^3}{g^2 Z^2} \right)^{1/5}$. Now, this relation we can use for computing critical depth directly. So, in a triangular channel, if the side slope Z is known, Q is known, then we can directly

calculate the Y_c . Now, let us see, can we have some relationship again for computing minimum specific energy or specific energy at the critical condition that on the basis of this critical depth.

(Refer Slide Time: 26:33)

**E and Y Relationship for
Critical condition (Triangular)**

$$E_{min} = Y_c + \frac{v^2}{2g}$$

$$= Y_c + \frac{Q^2}{(ZY_c^2)^2 2g}$$

$$E_{min} = Y_c + \frac{(2Q^2)}{4Z^2g} \frac{1}{Y_c^4}$$

$$= Y_c + \frac{Y_c^5}{4Y_c^4} = Y_c + \frac{Y_c}{4} = \frac{5}{4} Y_c$$

$E_{min} = \frac{5}{4} Y_c$

 $\Rightarrow$

$Y_c = \frac{4}{5} E_{min}$

So, this slide will be discussing about E versus Y relationship for critical condition is triangular channel. Let me again start from, say E is equal to specific energy E_{min} . We are talking about E_{min} is equal to Y_c plus v^2 by twice g . Starting from that we can write it as Y_c plus v^2 is equal to Q^2 by a square and that a square relationship as we could get here, that we can see is ZY_c^2 square. So, we can write ZY_c^2 square whole square and then, twice g . We just need to remember what relationship we got for this Y_c ?

So, that is Y_c is equal to twice Q^2 by gZ^2 square. Y_c we got as twice Q^2 by gZ^2 square Y_c to the power 5. Rather, Y_c to the power 5 is equal to twice Q^2 by gZ^2 square. Now, we need to express this particular expression. To have this expression, that is this expression twice Q^2 by gZ^2 square, so that we can have it terms of Y_c . So, let us just rewrite this and this from Y_{min} is equal to Y_c plus. If we write here twice Q^2 , just have it in this form. In this form, we can write here another two. So, it will become 4. Then, this ZY_c^2 square is already there. So, let me write it as Z^2 square and then g is here and Y_c , I am writing separately, Y_c to the power 4.

So, twice Q square by gZ square that expression we are getting here and that expression is nothing, but it is Y_c to the power 5. So, we can rewrite this expression as Y_c plus Y_c to the power 5 divided by $4Y_c$ to the power 4. This is nothing equal to Y_c plus 1 by $4Y_c$ or Y_c by 4 and that we can write as 5 by Y_c 5 by $4Y_c$. So, we can write as E_{minimum} , we can write as 5 by $4Y_c$. So, that is another relation that we can have for triangular channel. Y_c is equal to 4 by 5 E_{minimum} .

(Refer Slide Time: 30:27)

Computation of Critical depth

• Parabolic Channel

$$\frac{Q^2 T}{g A^3} = 1$$

$$\Rightarrow \frac{Q^2 K Y_c^{1/2}}{g \left(\frac{2}{3} K Y_c^{3/2} \right)^3} = 1$$

$$\Rightarrow \frac{Q^2 K Y_c^{1/2}}{g \frac{8}{27} K^3 Y_c^{9/2}} = 1 \Rightarrow$$

$$Y_c = \left(\frac{27 Q^2}{8 g K^2} \right)^{1/3}$$

$$A = \frac{2}{3} K Y_c^{1/2} \cdot Y_c$$

$$A = \frac{2}{3} K Y_c^{3/2}$$

$$Y_c = \frac{Q^2}{\frac{8}{27} g K^2}$$

Well, from these two analyses, we could see that for triangular channel and for rectangular channel, we can express minimum specific energy, that is, the energy at critical condition in terms of Y . Now, if it is a parabolic channel, let us see what sort of expression we can have or can we solve with directly, can we solve critical depth directly for parabolic channel. So, let us take a parabolic channel like this and the in parabolic channel, if this depth is Y_c , then this top width can be expressed in terms of Y_c as, say K some coefficient and Y_c to the power half.

This is our top width from the very basic expression of parabola. We can write it like, that top width is equal to $K Y_c$ to the power half and the area, that we can write as area is equal to $\frac{2}{3} K Y_c$ to the power half, that is what the top width and into Y_c two third. So, this becomes equal to $\frac{2}{3} K Y_c$ to the power $\frac{3}{2}$. So, that is the expression for area and K is a constant of the parabola.

So, using this expression again, if we start from the very basic relation, that is, $Q^2 T / (g A^3)$ is equal to 1. If we start from that again, then what we can write Q^2 and T top width is nothing, but $K Y_c$ to the power half. So, $Q^2 T$. Then, $g A^3$, we can write as $2.48 K Y_c$ to the power $3/2$, but this entire expression will have to be power to cube. So, this we can again simplify, rather our basic objective is to find out Y_c .

Well, let me write one more step here, that is $Q^2 K$ into Y_c to the power half g . Then, this 2.48 means 8 divided by 27 and then, we can write K cube and then, this will be Y_c to the power half Y_c to the power half. Sorry, this will be Y_c to the power $9/2$. Now, from this, if we write the Y_c , directly this is equal to 1 and from that, let me go this side, that is Y_c to the power $9/2$. If it is coming here, then it will be $8/2$. So, it will be Y_c to the power 4 or we can write Y_c to the power 4 directly. This expression, this Y_c and this Y_c combining, it will be Y_c to the power 4 . This is equal to Q^2 by $8/27g$ and this K , it is K square. So, that expression, we are getting, that is Y_c to the power 4 is equal to Q^2 by $8/27gK$ square.

Well, now using this expression, can we again just find one relationship between the minimum specific energy and Y and the critical depth Y_c again. We need to recall this relationship. This can be written in this form also, Y_c is equal to $2.48 Q^2 / (g K^2)$ to the power one fourth. This can be written like that also **ok**. Now, let me go to the next slide and see how we can calculate Y_c or how we can express Y_c , in terms of minimum specific energy.

(Refer Slide Time: 34:49)

**E and Y Relationship for
Critical condition (Parabolic)**

$$E_{min} = Y_c + \frac{v^2}{2g}$$

$$E_{min} = Y_c + \frac{Q^2}{A^2 \cdot 2g}$$

$$\Rightarrow E_{min} = Y_c + \frac{Q^2}{\left(\frac{2}{3} K Y_c^{3/2}\right)^2 \cdot 2g}$$

$$= Y_c + \frac{4 K^2 Y_c^3 \cdot 2g}{9 Q^2}$$

$$= Y_c + \frac{4 K^2 g Y_c^3}{9 Q^2} = Y_c + \left(\frac{27 Q^4}{8 K^2 g}\right)^{1/3} Y_c^2$$

$$E_{min} = \frac{4}{3} Y_c$$

$$= Y_c + \frac{1}{3} Y_c = \frac{4}{3} Y_c$$

Well, again minimum specific energy E_{minimum} is equal to Y_c plus v^2 by twice g . So, Y_c plus v^2 is nothing, but Q^2 by A^2 and twice g . Now, let me write this A^2 term and let me have this term here. So, that readily, we can write it in area terms is equal to $2/3$ by $K Y_c^{3/2}$. So, area is equal to Z square whole to the power $1/4$. Starting from that what we can write? This implies E_{minimum} is equal to Y_c and let me again rewrite this expression in the form.

So, that we can write Y_c for this particular expression, Y_c plus say Q^2 . Let it remain like that and then, area we will be writing as $2/3$ by $K Y_c^{3/2}$ square and twice g . So, this is equal to Y_c plus. This we can write as $4/9$ by K^2 square and Y_c to the power $3/2$, that is Y_c^3 and then, it is twice g . Then, Q^2 is remaining there. So, this expression, if we just try to write it in this form, then we can just write it like that Y_c plus, it will be $9/4$, but we need to get it as $27/8$. Let me write it as $9/4$. Then, it is Q^2 , then $K^2 g$ is there. So, this 2 and this 4 , this will become 8 , 2 and 4 .

This will become 8 and then, this is Y_c^3 , but still to express this in the form, that is $27/8$, we can write it in the form that Y_c plus. This we will write at $27 Q^4$ square, then $8 K^2 g$. This part is there and then, we will multiply it by $3 Y_c^3$. So, finally, this expression we can combine and we can write this as Y_c plus. This part is again Y_c to the power 4 . So, untimely it will be one third of Y_c and this can be written as $4/3$ by Y_c . So, the expression can be written as E_{minimum} is equal to $4/3$ of Y_c^4 by $3 Y_c^4$ by $3 Y_c$.

So, this is one relationship that we can have for a parabolic channel as such. We can see now that and computation of critical depth is not always, I mean very difficult, rather for most of the cases like rectangular channel, like triangular channel and then, like parabolic channel. Even, we can get it very directly, that is if we know why, if we know the discharge, if we know the channel section, then we can get the critical depth expression directly. So, computation is rather easy as compared to the computation of normal depth. Only for trapezoidal channel, we need to go for trial and error procedure.

(Refer Slide Time: 39:59)

Relationship between Critical Depth and Alternate Depth

$$\begin{aligned}
 y_1 + \frac{v_1^2}{2g} &= y_2 + \frac{v_2^2}{2g} \\
 \Rightarrow y_2 - y_1 &= \frac{v_1^2}{2g} - \frac{v_2^2}{2g} \\
 &= \frac{Q^2}{g y_1^3} - \frac{Q^2}{g y_2^3} \\
 &= \frac{Q^2}{g} \left[\frac{1}{y_1^3} - \frac{1}{y_2^3} \right] \\
 (y_2 - y_1) &= \frac{Q^2}{g} \cdot \frac{1}{2} \left[\frac{y_2^3 - y_1^3}{y_1^3 y_2^3} \right] = \frac{(y_2 - y_1)(y_1^2 + y_1 y_2 + y_2^2)}{2 y_1^3 y_2^3} \\
 \boxed{y_1^3} &= \frac{2 y_1^2 y_2^3}{y_1 + y_2}
 \end{aligned}$$

Well, let me go to another important relationship. We have seen that Y_c can be calculated and thus, energy at that Y_c can also be calculated and if we just recall our specific energy diagram, it was like that. Then, you can just concentrate on to the graph. Then for a specific energy E , we can have two depths, say this is Y_1 and this Y_2 . These two depths, we call as alternate depth, other than the minimum specific energy.

When it is minimum specific energy, then the depth we get is called critical depth. This is what our critical depth, but other than minimum specific energy, if we go to any other energy level, then we get two different depths for a specific energy, for a given discharge Q . These two depths, one is in super-critical condition and other is in sub-critical condition. Now, let us see, can we derive some relationship between the critical depth and these alternate depths. So, in this slide, we will be discussing about relationship between critical depth and alternate depth.

Well, let me write that as in these two points, specific energy is equal. So, what we can write, that is Y_1 plus, suppose velocity corresponding to this point is this depth is V_1 . So, Y_1 plus V_1^2 by twice g and that is equal to Y_2 plus V_2^2 by twice g . So, from this, we can say that Y_2 minus Y_1 is equal to V_2^2 by twice g minus V_1^2 by twice g . Sorry, V_1^2 by twice g minus V_2^2 by twice g . Now, for rectangular channel, what we can write for rectangular channel? This relationship is very popular and for rectangular channel, we can have this in this form, that is if it is Y_c , then this velocity V at any point can be written as Q .

Basically, first we can write it as area into, sorry Q by area and this is velocity equal to Q by area. Area is nothing but B into Y_c . So, this can be written as Q by Y_c . So, writing this, whatever may be the velocity, see here the velocity is V_1 and in the second section, velocity is or when the depth is higher, velocity is V_2 . Definitely, it is V_2 will be less than V_1 , but the discharge, there is the unit discharge or the discharge of the channel is not changing. So, if we are talking about this particular line, we are talking about this specific energy line for a given discharge.

So, when the discharge is same and if it is a prismatic channel, then our B is also same. So, that way, it is Q . This small q is not changing. So, whether it is V_1^2 or V_2^2 square, that we can write as in terms of Q square by Y_c Q square by Y_c and twice g minus Q square by Y_1 . Rather, at this point, it will be Y_1 . At the other point, it will be Y_2 Q square by Y_1 minus Q square by twice g into Y_2 .

So, taking this advantage, what we can write that we can write as 1 by twice gQ square by twice g . Rather, we can write Q square by twice g and then, it is 1 by Y_1 minus 1 by Y_2 by Y_1 minus 1 by Y_2 . Oh! Here, I did a mistake because this is V square. I am writing V is equal to Q by Y_1 . So, V square is equal to Q square by Y_1 square and this is equal to Y_2 square. So, it will be Y_1 square minus Y_2 square. So, this can be written as, again we know that Q square by g , that particular expression is nothing, but Y_c cube, if we recall our earlier expression.

So, Q square by g can be written as Y_c cube and then, it will be 1 by 2 . This part is Y_1 square Y_2 square. This will be Y_2 square minus Y_1 square and that can be written as Y_2 minus Y_1 into Y_2 plus Y_1 divided by twice Y_1 square Y_2 square and this here on the left hand side, we had Y_2 minus Y_1 . So, this Y_2 minus Y_1 , if we cancel, then we

can write that this Y_c^3 is equal to this part twice $Y_1^2 Y_2^2$ divided by $Y_2 + Y_1$. So, this expression finally, can be written as Y_c^3 is equal to twice $Y_1^2 Y_2^2$ divided by $Y_1 + Y_2$.

So, this is one of the very popular expressions. That is used when we want to know that what will be the, suppose if we know that a particular depth, we have Y_1 , then we want to know what is the alternate depth. Then, if we know the critical depth, we can calculate that. Suppose, we know Y_1 and Y_2 at a particular energy level, we know that this is Y_1 and that is Y_2 , then knowing Y_1 and Y_2 also, we can calculate critical depth. That is why while we are discussing the computation of critical depth, we are discussing this relation as well because this can be used for computing the value of critical depth.

Critical Depth in Compound Channel

• Choudhry and Ballamudi (1988)

Diagram of a compound channel cross-section showing a central rectangular section of width b_f and side sections of width b_s . The total width is $b = b_f + 2b_s$. The flow depth is y . The side sections have a sloped bottom with a horizontal distance x from the centerline to the edge of the side section.

Derivations:

$$Y_c^3 = \frac{Q^2}{g b^3}$$

$$\Rightarrow \frac{g b^3 Y_c^3}{Q^2} = 1$$

$$\frac{g b^3 Y_c^3}{Q^2} = K$$

For $K = 1 \Rightarrow Y_c = Y_f$

For $K < 1 \Rightarrow Y_c > Y_f$ → critical flow in the rectangular portion.

For $K > 1 \Rightarrow Y_c < Y_f$ → critical flow occurs in the side portion.

Side section width $b_s = \frac{y}{\eta_f}$

Rectangular portion width $b_f = \frac{B_f}{\eta_f}$

Total width $b = \frac{B_f}{\eta_f} + 2 \frac{y}{\eta_f}$

Well, then, let me discuss another topic very briefly. Of course, this topic is critical depth in compound channel and this need to be discussed very elaborately, but it is beyond the scope of this particular course. That is why, just to give you some idea or just to have some discussion on this topic, let me discuss it briefly. Well this, let us draw one compound channel and let us see how we can have some peculiar relationship for critical depth computation in compound channel.

In fact, Chaudhry and Ballamudi in 1988 did this sort of analysis by symmetrical compound section. What we mean that these are identical. This left hand side, right sides are identical. This is a compound channel and then, say depth flow at any level, may be

Y here, then this B we can write as B_m . That is the main channel and always we know that in a compound channel, when the depth of flow will be less or discharge will be less, then flow will be concentrated, sorry the flow will be flowing through the main channel. Of course, concentrated flow goes through. The flow concentration is always in the central part and then, on the side, the flow will be less. Rather, the flow velocity will be less. Then, this level we call as depth up to the floodplain Y_f and this portion is call width of the floodplain B_f . As it is symmetrical, so this side also it will be floodplain width, the same B_f .

So far, Manning's roughness is concerned; here we can write that this is n_m , main channel roughness. This is, say floodplain roughness and then in the compound channel, using this term, some non-dimensional term can be derived say Y_r , that is, equal to Y depth of flow at any point divided by Y_f . This is say non-dimensional term regarding depth. Then, we can have breadth related non-dimensional term, that is, equal to floodplain width divided by say, sorry floodplain width divided by width of the main channel B_m .

Then, we can have another term B_f . This is equal to B_f divided by Y_f . Then, we can have this n_r , that is, equal to n_m divided by n_f . Now, this is just non-dimensional term which is used for obtaining or for analyzing this critical flow computation. Of course, as I have already mentioned that we do not have that much of scope to go in detail of these analyses, but still we can have some of the understanding.

Well, now we know that Y_c , as we have already discussed say Y_c is equal to, we can have Q^2 by gY_c^3 is equal to Q^2 by g . So, if it is Q^2 by g , means small q is equal to q by B and when we talked about this rectangular portion, that is the lower portion of the compound channel, this particular portion. Then, it is just simple rectangular channel and we can have this expression, that is, Q^2 by g . That Q^2 we can write Q^2 by B^2 small q^2 . So, q^2 by g and Y_c^3 is equal to Q^2 by g . So, this is say, B_m . Now, this we can write as at critical condition, it is like that Y_c^3 is equal to, so this can be written as gB_m^2 . Then, Y_c^3 by Q^2 is equal to 1. I mean from that we can write this one.

Now, let us see, if for a particular discharge, if our critical depth lies below this channel, below this floodplain depth, then we can use this expression directly because up to this

point, we do not have anything, nothing like compound channel. Here, it is just simple rectangular channel. Now, we can calculate if in place of Y , say that means, upto Y_c is equal to Y_f . If your Y_c remains Y_f , then we can have this sort of relationship.

So, we can write one expression that gB^3 square, then say, Y_f^3 cube by Q^2 square. Let us define this as K . Now, from this expression, we can have some understanding that if our K is equal to 1. So, K is equal to 1 means Y_c . This implies that Y_c is equal to Y_f . Now, if K is less than 1, then 1 means Y_c , that is it is less than y means Y_f is less than Y_c . So, Y_c is greater than Y_f . Well, now what it indicate Y_c greater than Y_f means critical depth.

If you just refer this diagram, critical depth will be greater than Y_f . That means, greater than this particular depth. So, when critical depth is greater than this particular depth, that means we cannot have critical depth below this main channel, below the floodplain level. In that case, that will not be valid because up to this portion only, we can have rectangular. So, this we can consider, this is rectangular channel. So, this implies that critical flow cannot occur within the, let me write critical flow, cannot occur in the rectangular portion.

Now, if we have another condition that K is greater than 1. So, K greater than 1 will indicate Y_f is greater than Y_c . Now, if our floodplain depth B_f , sorry if our floodplain depth Y_f is greater than critical depth, that means the critical depth will occur or critical flow will occur within the rectangular channel. So, this will lead us to that condition that critical flow occurs in the rectangular portion.

So, when critical flow occurs in the rectangular portion, then this we can calculate directly. Now, when critical flow is occurring somewhere here, when the flow is over floodplain that means from this analysis, what we are getting that, if the flow is critical depth is occurring, what the flow is occurring above the floodplain. Then only, that is when the flow depth somewhere here, then we can have some complexities in computing critical flow, when it is below this. Yes, we can do it directly and for that another term was defined.

(Refer Slide Time: 56:48)

That term is called C , which basically relates, that is Y_r b_f r . Those non-dimensional relationships, B_f and N_r and this C mean, when this K expression is equal to C , then we can have critical flow condition. Well, that C , we can plot like this. That means, on this side, if we plot Y_r , basically for a section for other things remaining the same. Say, our B_r , as we could see, just to again go back, B_r is equal to B_f by B_f by B_m . It should be written B_m ; sorry B_r is equal to B_f by B_m .

So, as we can see that this B_f B_m , suppose for a given section, if these are constant B_f Y_f these are constant, but this Y_r will be varying with that depth, that means when depth changes, Y_r is varying N_m and N_f . This N_r ratio is also remaining the same. So, ultimately from this expression, if for a given section, for a given roughness, everything remaining the same C becomes a function of Y_r . So, we can plot Y_r versus C and C and Y_r . Y_r will start from 1. If you just go back to this expression, Y_r is nothing, but Y by Y_f .

So, when Y is equal to Y_f , this Y is equal to Y_f . The depth flow is this much. We are getting it below the rectangular portion. Now, our point or we are now interested when it is above this thing. So, when Y will be exceeding this Y_f , then Y_r become higher than 1. So, when it is higher than 1, then we are interested what will happen then. We are talking about this term C .

So, this is say 1. This is 0.123. If we get like that, depending on the section, we can have different sort of curve. This will be 1, say 1.1, 1.2. That way the ratio is gradually increasing and then, we can have a curve like this. We can have a curve like this and then, when we calculate the K value, that K value, what we got earlier, this K value. Then, if we see that in this curve, K can be greater than, there we are getting a value C_{max} , maximum value of C for a given section. If our K is, suppose K value we are calculating and K is greater than C_{max} , this can be one condition. Say, this is case 1.

Case 1, we are getting K is greater than C_{max} . Then, we can have another condition that now, here we can see when case 1, K is greater than C_{max} means, this on the floodplain, when the flow is above floodplain, we are not getting any intercept of this K value with the C_{max} . That means, it directly means that no critical flow will occur in the upper portion of the compound channel because we are talking about upper portion of the compound channel as Y_r ratio is higher. So, no critical depth will occur in the upper portion of the compound channel.

Well, critical flow will occur only in the lower portion of the compound channel, that is, the condition. When we have, say if our case 2, if we can have this K is less than C_{max} and we can have K is greater than 1. That means, it is above 1 and is less than C_{max} means somewhere here, this K value. Now, if it is like that, that means, we are finding there will be one critical depth where K is equal to C. Here, one point and this is above the floodplain Y_r ratio 1.1 and 1.2 between. So, it is higher than that. So, at some point, it will be there and another critical depth we are getting here, where it is just likely higher than Y_r . Y_r is slightly higher than 1 means just near the floodplain, we are getting this thing.

If I draw this compound section, that means, Y_r is just greater than 1 means just here somewhere, we are getting one critical depth, say Y_c . We are getting $1Y_c$ and another Y_c we will be getting here which correspond to this value. So, this condition indicates two critical depths. One will be there above the floodplain, $2Y_c$ above the floodplain. So, that is what we are getting. Of course, as K is greater than 1, from this condition, we got when K is greater than 1, there will be another critical depth below the floodplain. So, $2Y_c$ and $1Y_c$ below floodplain, so that also we are getting.

Then, we can have another case 3. When our K is less than C_{max} and also K is less than equal to 1. That means, if we are coming below this 1, then it is going like this and we are getting one critical depth above the floodplain. So, this will lead to one critical depth above the floodplain and obviously as K is less than 1, we will not get any critical depth below the floodplain level. That is why from these conditions, we can see that there will be a, if draw the specific energy diagram, this is a floodplain level.

(Refer Slide Time: 1:03:06)

For case 1, there will be no critical depth here and there will be a change in the diagram. This is the critical depth. This is case 1. Then, for case 2 what will happen, there will be one critical depth here. Then, energy diagram is going like that and then, it is coming like that. So, there will be three critical depths. Two above the floodplain and one below the floodplain 1 2 3 and here, it is only one. For the third, this is case 2 and for the third case, what will happen, there will be a critical depth above the floodplain, but there will be no critical depth below the floodplain. This is what one critical depth. So, that is why in compound section, we can have three critical depth conditions, three critical flow conditions. For all these specific energy is of course minimum. Here, specific energy is minimum in the case 1. Specific energy is minimum for two cases. In the case two, but for case 1, specific energy is not even minimum. So, this sort of different conditions, we can have for computing critical flow in compound channel.

Well, this much is, I think sufficient who have some understanding of critical depth computation in compound channel. In the next class, we will be going in more detail into the critical flow computation. We will be solving some numerical. That way, we will try to see how critical depth computation can be done for the different types of channel and how this critical flow computation helps us in studying other aspect of hydraulic engineering. Thank you very much.
