**Functions of Multiple Random Variables (Contd.)**

Hello and welcome to this tenth lecture of this module. You know that in this module, we are discussing about this multiple random variable, and it is, in last couple of classes, we are discussing about the functions of multiple random variable. So far we have discussed about one function of two random variables and their general cases and their application to different problems we have seen, and specially in the last class, we have seen that one example on the Civil Engineering problem that, how one function, how to determine the p d f of the functions of the random variable.

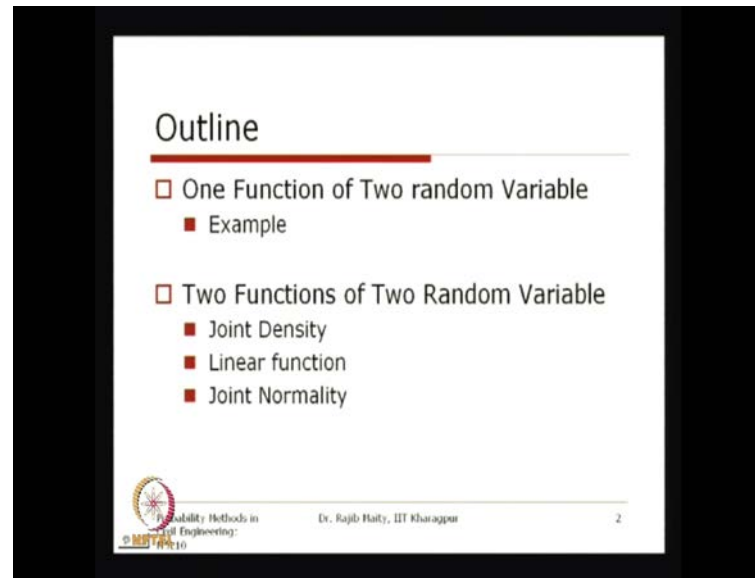

So, today's class basically, we will be, **we will be**, going through **the if there are** more than one, one, function. So, that means, the known random variables are say  $x$  and  $y$  and there are two more new functions are there say  $z$  or  $w$  based on this earlier random variable  $x$  and  $y$ . So, we will be interested to know that what is the joint density of these new functions, that is,  $z$  and  $w$ . So, now, you know that whatever we have discussed earlier that once we know their joint density, and from there, we can you can even obtain whatever we need, for example, the marginal densities, we can obtain, we can obtain their conditional density and all.

So, the focus of our today's class is to discuss about the, their density or rather the joint density of two functions of the two random variables, and of course, we will take this one from this 2 by 2 case to this general case from this  $n$  numbers of variables to  $m$  numbers of new functions. So, that we will generalize later.

But to start with today's class, we will take one more example from this one function of out of two random variables and we will take this problem in such a way that there are more than one root. If you recall that couple of class before, we discussed that whenever we are having more than one root, then we have to take a summation of for all the possible roots

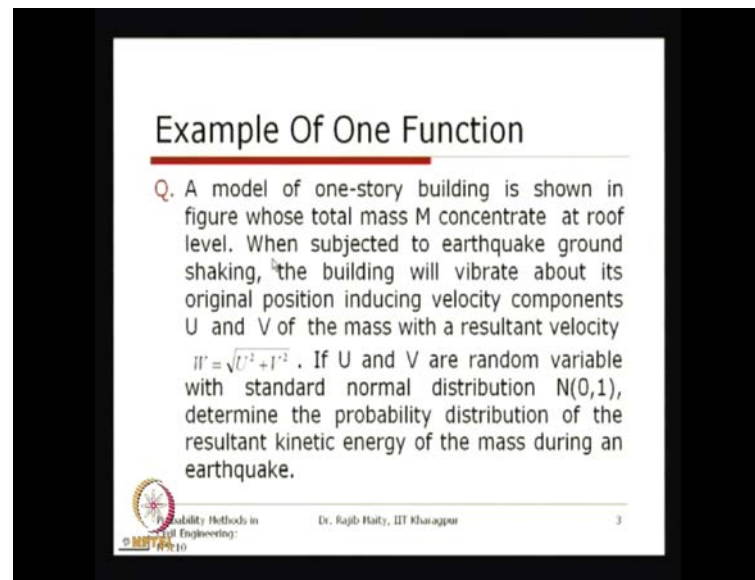

and that type of one example we will take, which is again **the** only a single function out of the two random variable. So, we will start with that and then we will go to these two functions of two random variables.

(Refer Slide Time: 02:36)

So, our outline is this one, **one** function of two random variables. So, we will put one example, and after that, we will go to that the two functions of two random variables and we will discuss their joint density, linear function, joint normality. This is important because, so, when most of the cases or many cases, I should say that there are random variables which are jointly normal. Joint Gaussian distribution is observed, and if they are having two new functions, then what is their distribution properties and all. So, to start with as I was telling that, we will just take one, **one**, more example of this one function of two random variables.

(Refer Slide Time: 03:20)

**Example Of One Function**

Q. A model of one-story building is shown in figure whose total mass  $M$  concentrate at roof level. When subjected to earthquake ground shaking, the building will vibrate about its original position inducing velocity components  $U$  and  $V$  of the mass with a resultant velocity  $W = \sqrt{U^2 + V^2}$ . If  $U$  and  $V$  are random variable with standard normal distribution  $N(0,1)$ , determine the probability distribution of the resultant kinetic energy of the mass during an earthquake.

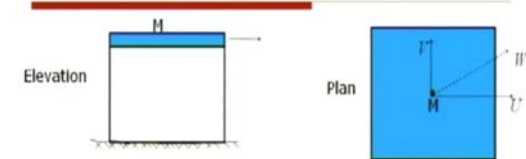

Probability Methods in Civil Engineering  
Dr. Rajib Haity, IIT Kharagpur

And this example is based on the, **based on the**, kinetic energy that is being stored in a structure during a earthquake time. So, the, you know that during the, during the earthquake, generally, the, a structure vibrates and vibrates and we can have their velocity component in two orthogonal direction and their resultant direction, resultant velocity we can obtain and we may be interested to know what is the property of that, **of that**, resultant kinetic energies.

So, based on that, we will be taking a simplified structure, and here, the one, **one**, storied simplified structure has been obtained and in that structure there. So, the idealized case you know that, if you have that the general way of analyzing, this earthquake force is a we generally assume that concentrated mass at the, at the floor level, and based on that, we obtain some force at that level and we calculate what is the kinetic energy. So, here, we will be taking one such problem for one idealized one storage structure. So, this problem statement is that a model of one-story building is shown in the figure. So, let us see the figure first.

(Refer Slide Time: 04:40)

**Example...Contd.**

**Sol.:**  
The resultant Kinetic energy:  

$$K = \frac{1}{2} M W^2 = m W^2 = m (U^2 + V^2)$$
 Let  $A = mU^2$  and  $B = mV^2$ , so  $K = A + B$

Probability Methods in Civil Engineering: Dr. Rajib Baiti, IIT Kharagpur 4

So, this is the one storied building, and as I was telling that mass  $M$  is concentrated at its first floor level. So, whose total mass  $M$  concentrated at the roof level, and when subjected to the earthquake ground shaking, the building will vibrate about its original position inducing the velocity components  $U$  and  $V$ . So, this  $U$  and  $V$  are in two orthogonal directions of the mass with the resultant velocity. You know that if the  $U$  and  $V$  are the velocity component in two orthogonal direction, then their resultant velocity will be denoted as  $W$  and  $W$  is equals to square root of  $U$  square plus  $V$  square.

Now, if  $U$  and  $V$  are the random variable with standard normal distribution, that is, it is a normal distribution with mean 0 and standard deviation 1. So, we know that how this, how this distribution function is. So, both of them, that is,  $U$  and  $V$  are distributed as the standard normal distribution they follow.

So, our, so, what we have to determine is that probability distribution of the resultant kinetic energy. Now, this so, if this is the force, then we have to first know that what should be the kinetic energy, and then, we, we will be able to determine what is this probability distribution. The information that we know that the marginal density, that is the density of the  $U$  and  $V$  are known to us. We just standard normal distribution. So, determine the probability distribution of the resultant kinetic energy of the mass during an earthquake.

So, as we are just explain in the problem that this is the mass that is concentrated at the first floor level, and if we just see it from the top, so this is the component of this velocity U and this is the component of velocity V and their resultant is W and which is you know that the square root of u square plus V square.

Now, if we see their kinetic energy, then this can be explained; this can be denoted as K and this can be finally written that this m U square plus V square. So, basically, we are having two random variable which are, for, for which, the distribution is the standard normal distribution and we are just adding them up after squaring them. So, U and V we know. So, what is the distribution of the U square plus V square, where U and V both are standard normal distribution? That is the basic question here. So, you see that if we just know denote that A equals to m U square and B is equals to m V square, so we can write the total resultant kinetic energy is equals to A plus B.

(Refer Slide Time: 07:38)

**Example...Contd.**

□ Taking  $a = mu^2$

$$u = \pm \sqrt{\frac{a}{m}}$$

Thus

$$\frac{du}{da} = \pm \frac{1}{2\sqrt{ma}} \quad \text{or} \quad \left| \frac{du}{da} \right| = \frac{1}{2\sqrt{ma}}$$

We know

$$f_A(a) = \sum_{\text{for all } u} \frac{f_U(u)}{\left| \frac{da}{du} \right|}$$

Probability Methods in Civil Engineering  
Dr. Rajib Hait, IIT Kharagpur  
5

So, now, we will see what is their distribution of the A and B first. Now, this one if we just take the specific value of the random variables, we can write that a equals to m u square. So, that u will have the plus minus square root a by m. Now, you see that here we are getting the two roots.

So, we have to whatever the distribution that we will get, we have to get it for the both this, both this roots, and now, there we have discussed it earlier how to get their distribution of their functions. So, we have to get their Jacobian, that is, d u by d a

Now, we know that for this, if we want to know what is the distribution of this  $a$ , when we know that distribution of this  $u$ , then we have to multiply it by its Jacobian or divide by its inverse of this one, that is,  $da/du$  of this absolute value and we have to do it for all the roots that is for all  $e^u$ . Now, here, there are two roots that we, as you can see, and we also know what is the distribution of this  $u$  which is a standard normal distribution.

## Example...Contd.

- In accordance with the previous equation, density function
 
$$f_A(a) = \left[ f_V\left(\sqrt{\frac{a}{m}}\right) + f_V\left(-\sqrt{\frac{a}{m}}\right) \right] \frac{1}{2\sqrt{ma}}$$

$$= \frac{1}{\sqrt{2\pi ma}} \exp\left(-\frac{a}{2ka}\right) \text{ for } a \geq 0$$
- Similarly
 
$$f_B(b) = \frac{1}{\sqrt{2\pi mb}} \exp\left(-\frac{b}{2m}\right) \text{ for } b \geq 0$$

which is a chi-square-distribution with one degree of freedom

Probability Methods in  
Civil Engineering

Dr. Rajib Halty, IIT Kharagpur

6

So, so, this is the distribution of  $a$  that we got from what we know that. So, here, what we have to do is that maybe one more step could have been shown here is that, this is the  $f_U$  of this component means that you are, you are putting their standard normal distribution. You know that how to, what is the form of the standard normal distribution,

and so, it will be just that 1 by square root of pi because the sigma is the 1, then exponential of minus half of this one because the mean is 0 and standard deviation is 1. So, if we put both these things into places with this respective, this component that will one is the square root a by m and other one is this minus square root of a by m, and then, if we add them, then we will get this form.

And for the b also the expression is same, that is, now this capital B is equals to, capital B is equals to m u square m v square, **v square**, and v is also having the same standard normal distribution. So, from there, if we want to know what is the distribution of this b; then b distribution also will be the similar one with this parameter change as b. So, it will be 1 by square root of 2 pi m b exponential minus b by twice m for b greater than equal to 0. So, which is a chi-square-distribution with one degree of freedom that we know this distribution, and now, if we want to know what is the distribution for the k and this k you know that k equals to a plus b.

(Refer Slide Time: 11:27)

**Example...Contd.**

□ Taking  $b = K - a$

$$f_k(k) = \frac{1}{2\pi m} \int_0^k \frac{1}{\sqrt{a}} e^{-a/2m} \cdot \frac{1}{\sqrt{k-a}} e^{-(k-a)/2m} da$$

$$= \frac{1}{2\pi m} e^{-k/2m} \int_0^k (a)^{-1/2} (k-a)^{-1/2} da$$

□ Taking  $r = a/k$ ; i.e.  $da = kdr$

$$f_k(k) = \frac{1}{2\pi m} e^{-k/2m} \int_0^1 (r)^{-1/2} (1-r)^{-1/2} dr$$

© 2014 IIT Kharagpur

Dr. Rajib Haty, IIT Kharagpur

7

So, k equals to a plus b and that can be arranged, that is, b equals to k minus a, and from these addition in the last class also we discussed that last class or that last to last class that a plus b if one function, then how to get the distribution of that one. So, we are using the same thing. It can be expressed in the two different way - one is that you just explain the function in terms of only one variable either a or b and do this integration for the entire range for the variable that you have kept.

So, here, so, one such is this. So, here, we are keeping that variable  $a$  here. So, this, so, this is the distribution of this, **of this**,  $a$  and this is the distribution of the  $b$  expressed in terms of  $k$  minus  $a$ . So, now, we are just eliminating out the  $b$ . So, we will do this integration for the entire range of this  $a$ . So, that is why it is 0 to  $k$  and this is integration with respect to  $a$ . Now, if we do this integration, then we will get that  $1$  by  $1$  by  $2\pi m$  exponential of minus  $k$  by  $2m$  integration 0 to  $k$   $a$  power minus half  $k$  minus  $a$  power minus half  $d a$ .

Now, so, this integration if you want to do, that is, the closed form; integration is not available, but if you just replace this  $a$  by  $k$  by  $r$ , so this  $a$  by  $k$ , then it can be expressed that this integration limit will be 0 to 1 and it will be  $r$  power minus half and  $1$  minus  $r$  power minus half  $d r$ .

Now, this is nothing but a, nothing but a, beta function, beta function, with parameter half and this also half. So, beta half comma half this is a, **this is**  $a$ , function which also can be expressed in terms of this gamma function and gamma function few values few standard values we know. So, this integration component we can get from that gamma function which is explained here.

(Refer Slide Time: 13:32)

**Example...Contd.**

□ The integral part is the beta function  $B(1/2, 1/2)$

$$B\left(\frac{1}{2}, \frac{1}{2}\right) = \frac{\Gamma\left(\frac{1}{2}\right)\Gamma\left(\frac{1}{2}\right)}{\Gamma(1)} = \pi \quad \text{since } \Gamma\left(\frac{1}{2}\right) = \sqrt{\pi}$$

□ Hence

$$f_K(k) = \frac{1}{2m} e^{-k/2m}$$

is a chi-square distribution with two degrees of freedom

Probability Methods in Engineering: Dr. Rajib Baitty, IIT Kharagpur

So, this beta half, **half**, is equals to this gamma half multiplied by gamma half by gamma 1. So, which is now equals to  $\pi$ . You know that this gamma half is equals to square root  $\pi$ .

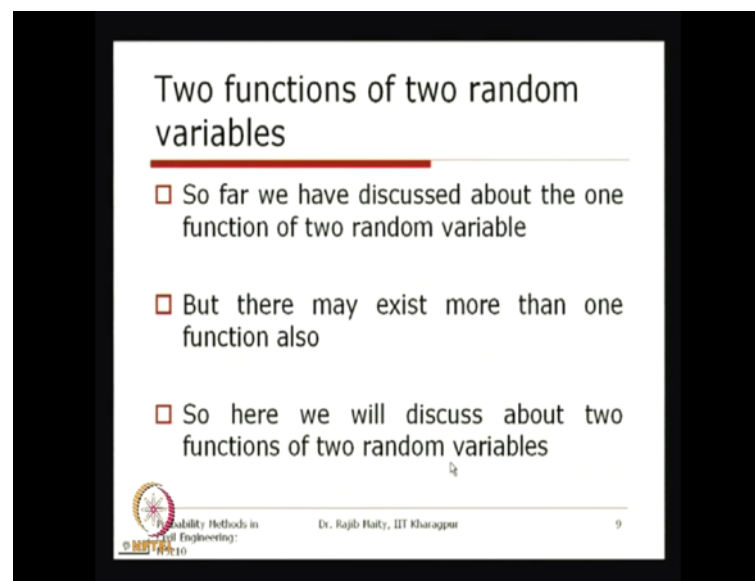

So, if we are, so, we are getting this beta half, half is pi. So, basically so this integration is the value of this integration is pi and that pi and this will cancel.

So, this final form of this distribution of this random variable  $k$  will be your  $1$  by  $2$   $m$  pi cancelled power minus  $k$  by twice  $m$ . Now, you know that this also a chi-square distribution with two degrees of freedom which is nothing but the distribution of the total kinetic energy induced during the earthquake time, earthquake time.

So, now means, now the, once we know this distribution, obviously this support is  $k$  is you know, it is forgot to mention here that this  $k$  is greater than equal to  $0$ . So, now, once we get this support and this will be now whatever the property that we know, that we can, **that we can obtain** and that we have discussed in earlier classes as well once the distribution is known all other properties can be assessed.

(Refer Slide Time: 14:55)

Two functions of two random variables

- So far we have discussed about the one function of two random variable
- But there may exist more than one function also
- So here we will discuss about two functions of two random variables

 Reliability Methods in Civil Engineering: Dr. Rajib Haity, IIT Kharagpur 9

So, now, we will go to the two function as I was telling that sometimes we need to, we need to know what is the, there could be it is possible to have; that means, two more functions out of the whatever the, whatever the random variable that we are having. So, if we are now talking about more than one new random variable. So, you know that this functions are also random variable. So, if you are talking about that more than one new random variable, then we will be interested to know what is their joint density.

So, and also you know that if we know the joint density, then from the joint density, we can get their marginal's or whatever the distribution or the their properties we can, we can, assess. So, that is why so far we have discussed one, one function, and here, we will see some one more interesting point is that, sometimes even though we are, we are, looking for a single function and it will be, soon that it will be even sometimes easier to introduce a dummy function means a another new function of your own choice and follow the procedure to obtain the joint density of the two new random variable, and then, you get that marginal density of the random variable that is of interest to you.

So, sometimes this procedure is found to be mathematically more easier than to get the distribution of a single function out of two random variable. That we will discuss. So, the, our motivation here is that we have discussed about the one function so far out of two random variables, but there it will be variables, but there may exist more than one function also. So, here, we will be discuss about this two, two functions of two random variables and also gradually we will take this same concept to for the, for the, m functions out of n random variables. So, that will be the general case.

(Refer Slide Time: 17:06)

Two function of two random variables...Contd.

- Let  $X$  and  $Y$  be the two random variables with joint pdf  $f_{XY}(x, y)$
- Two functions  $g(x, y)$  and  $h(x, y)$  are used to define two new random variables,  $Z = g(X, Y)$  and  $W = h(X, Y)$
- We are interested to determine the joint pdf between  $Z$  and  $W$ , i.e.,  $f_{ZW}(z, w)$
- Once  $f_{ZW}(z, w)$  is determined, then the marginal pdf's  $f_Z(z)$  and  $f_W(w)$  can be easily determined

Probability Methods in Electrical Engineering  
Dr. Rajib Halty, IIT Kharagpur  
10

Well, so, what we are having is that two random variables is there. Let that  $X$  and  $Y$  be the two random variables with the joint pdf  $f_{XY}(x, y)$ . So, we have two random variables and their joint pdf is known to us; that means, we know whatever the properties their

marginal distribution everything we know if we know their joint distribution. So, this joint distribution of this two random variable X and Y is known.

Now, there are two functions - one is that  $g(x, y)$  and other one is  $h(x, y)$  are used to define the new random variables. So, you know that these functions are also the, also a random variable only. Suppose that we are denoting that  $g(x, y)$  as the  $z$  and this  $h(x, y)$  as the  $w$ . So, what we are interested is, to determine the joint density or the joint p.d.f between this  $Z$  and  $W$ , that is,  $f_{ZW}(z, w)$  express in terms of their lower case letters.

So, once we know this one, then you know that as, as we have started that the joint p.d.f of  $x$  and  $y$  is known means we know their whatever the properties we need to know. Similarly, if we can obtain this joint density of this, of their functions, then whatever we need to know we will be knowing. For example, their marginal p.d.f's of this  $Z$  and  $W$ . This  $f_Z$  expressed in terms of  $z$  and  $f_W$  expressed in terms of  $w$  can also be easily determined from the theory that we have discussed earlier. So, now, we are interested to know what is that the joint density of  $f_{ZW}$  from the joint density of  $f_{XY}$ , where  $x, y$  is my original random variable and  $Z$  and  $W$  are the functions of this original random variable  $X, Y$ .

(Refer Slide Time: 19:10)

**Two function of two variables...Contd.**

- Determination of  $f_{ZW}(z, w)$  can be done similar to the one function of two random variable i.e.

$$\begin{aligned}
 F_{ZW}(z, w) &= P\{Z(\xi) \leq z, W(\xi) \leq w\} \\
 &= P\{g(x, y) \leq z, h(x, y) \leq w\} \\
 &= P\{(x, y) \in R_{z,w}\} = \iint_{R_{z,w}} f_{XY}(x, y) dx dy
 \end{aligned}$$

Since the region  $R_{z,w}$  of the  $xy$  plane such that the inequalities  $g(x, y) \leq z$  and  $h(x, y) \leq w$  are simultaneously satisfied

Probability Methods in Electrical Engineering: Dr. Rajib Halty, IIT Kharagpur 11

Now, the determination of this joint density  $f_{ZW}$  can be done similar to the one function of two random variables. Basically, the, keeping the fundamental concept same, what we can express is that their cumulative density, that is,  $f_{ZW}$  express in terms of  $z$  and  $w$  can

be express at that probability that this, that is,  $z$  for a specific outcome of  $x$  and  $y$  in the sample space, it should be less than or equal to  $z$  and  $w$  should be less than or equal to  $w$ . So, this comma you know that. That also we discussed earlier also. This comma here indicates that the simultaneous occurrence of both these events.

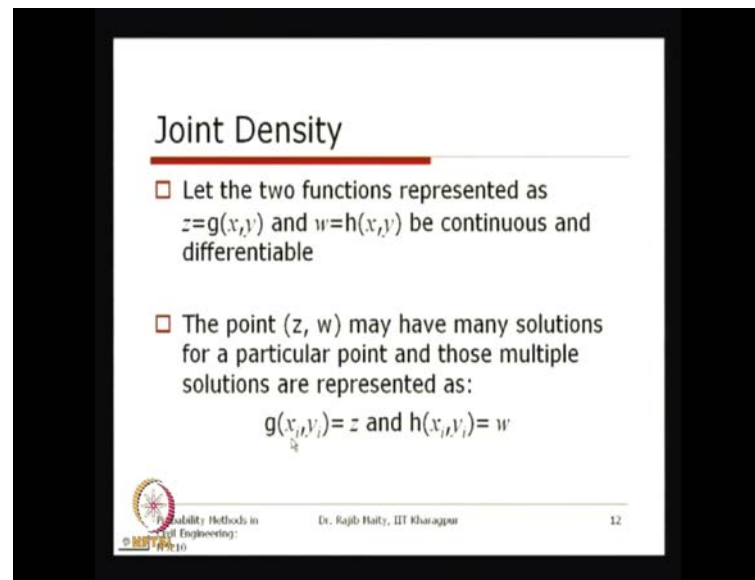

So, in whatever cases, the, both these events occur. Simultaneously we will get the probability and that probability is nothing but the cumulative probability of the joint distribution between  $z$  and  $w$ . Now, this one can be again, again, express that, you know that this  $z$  is the function of this  $g(x, y)$ . So, this can be expressed in terms of  $g(x, y)$  which is less than or equal to  $z$  and this can be expressed as  $h(x, y)$  less than or equal to  $w$ . So, basically what is express is that this  $x, y$ . So, that we are looking for a subset  $x, y$  which belongs to a specific set  $R$  denoted by  $R(z, w)$ . So, this is the probability where this condition, this simultaneous occurrence of these events is satisfied.

So, once we know this region that means I have to integrate the joint density of the  $x$  and  $y$  over that region only. So, this is the integration as there are two random variables. This is the double integration over the region of this  $R(z, w)$ , where this condition are this, this, joint occurrence is satisfied.

So, what is this region  $R(z, w)$ ? So, since the region  $R(z, w)$  of this  $x, y$  plane, such that the inequalities this  $g(x, y)$  less than or equal to  $z$  and  $h(x, y)$  less than or equal to  $w$ ; that means, these two events are simultaneously satisfied. So, this simultaneously word is important here as I, as I, was telling that both this event should be satisfied simultaneously. So, that that is what it means the joint occurrence and then only we will get what is the joint distribution. So, this is straight forward; straight forward in the sense that this is the fundamental concept where even while discussing about the one function out of two random variable.

So, this fundamental concept was same. Only thing is that there the resulting function was a one-dimensional means that only for the single random variable. Here, we are going from one-two dimensional plane to another two-dimensional plane. So, it is map from the one surface to the another surface. The first surface is the  $x, y$  consist of this original two random variable and the other surface that we are talking about is this  $z, w$  which is mapped from this  $x, y$  through this functional dependence  $g(x, y)$  and  $h(x, y)$ .

(Refer Slide Time: 22:33)

**Joint Density**

- Let the two functions represented as  $z=g(x_i, y_i)$  and  $w=h(x_i, y_i)$  be continuous and differentiable
- The point  $(z, w)$  may have many solutions for a particular point and those multiple solutions are represented as:  
$$g(x_i, y_i) = z \text{ and } h(x_i, y_i) = w$$

 Probability Methods in  
Engineering: Dr. Rajib Halty, IIT Kharagpur 12

So, now, let the two functions represented as this  $z$  equals to  $g \times y$  and  $w$  equals to  $h \times y$  be continuous and differentiable. So, if we just going on **this** with this assumption, so basically what we are talking about these random variables are the continuous random variable, and whatever the function that we have taken that is differentiable at every  $u$  point.

Now, the point  $z, w$  may have many solutions for a particular point and those multiple solutions are represented as that  $g \times i \times y \ i$  is equals to  $z$  and  $h \times i \times y \ i$  is equals to  $w$ . So, now, for the, so, it can happen that from the surface from the plane  $z, w$ . For one combination, we could have, we could have multiple solution means multiple representative point on the  $x, y$  plane and those are denoted by this  $x \ i \ y \ i$ .

(Refer Slide Time: 23:34)

**Joint Density ...contd.**

- Now the probability can be represented as:  

$$P\{z < Z \leq z + \Delta z, w < W \leq w + \Delta w\}$$

$$= P\{z < g(X, Y) \leq z + \Delta z, w < h(X, Y) \leq w + \Delta w\}$$
- It can be rewritten as:  

$$P\{z < g(X, Y) \leq z + \Delta z, w < h(X, Y) \leq w + \Delta w\}$$

$$= \int_{z}^{z+\Delta z} \int_{w}^{w+\Delta w} f_{ZW}(z, w) \Delta z \Delta w$$
- Now to evaluate the equivalent of  $\Delta z \Delta w$  in the xy plane, let us consider the point A in the given figure

Probability Methods in Electrical Engineering  
 Dr. Rajib Halty, IIT Kharagpur  
 13

So, if that is the case, now from the concept of this probability, that we can be, we can express that the probability of Z from a very small region of this delta z, that is, Z lying between z and z plus delta z. So, remember that this capital letter as I was telling I told earlier also that this capital one is the random variable and the lower case letters are the specific values. So, this random variable z in between that z and z plus delta z and simultaneous occurrence of this W in between w plus w and w plus delta w which can be also, which can be also written as this. In place of this z, we can write that that function g and this w can be replaced by the function h. So, if these values are in between this small area of this delta z and this delta w.

It can also be written as this function is equals to nothing but their the density, the probability density at that point; that point means the z w multiplied by that elemental area. Area means here we are talking about the two random variable that, that is why it is area, so that density multiplied by this small elemental area. So, that will be the total probability. Now, see the difference here from the single random variable to the two random variables here, is the single random variable. Whenever we are discussing, we are discussing about the probability density multiplied by a small elemental length over the a axis represented, **represented**, by the random variable.

So, that the area itself is giving you the probability, but here, when you are we are taking it to, to the two-dimensional case, that means I have to consider a volume that is a

density multiplied by the small area below that density curve. So, that will give the probability. Similarly, you can even extend this one to this even for the three random variables, four random variables. So, that will be some hyper plane and the hyper volume to represent that probability.

So, here, for the two-dimensional case, the density multiplied by the small area which is the probability of this joint occurrence of this two event. Now, to evaluate the equivalent of this area, that is, this  $\Delta z$  and  $\Delta z$  multiplied by  $\Delta w$  which is the, which is the, area on the plane represented by the new random variable, that is,  $z$  and  $w$ . Now, this area I have to find out what is the equivalent area on the  $x$   $y$  plane that is the original random variable. So, let us consider a point  $a$  in the given figure.

(Refer Slide Time: 26:32)

So, here, you can see that this is the plane which is by, made by this  $z$  and  $w$ . So, here, the point that we are talking about the  $A$  and  $A$  is the, is the coordinate having that  $z$  and  $w$ . Now, we have considered a small elemental area means surrounded by this  $A$   $B$   $D$  and  $C$  and this  $A$   $B$  is your  $\Delta z$  and this  $A$   $C$  is your  $\Delta w$ .

Now, we are interested to know so that some equivalent area or equivalent or the representative of the same area in this  $z$   $w$  plane on the  $x$   $y$  plane. So, you know that this will be obviously be distorted and that equivalent area if we represent at this represented by this  $A$  prime  $B$  prime  $D$  prime and  $C$  prime and this total area as we are talking about is the  $\Delta I$ .

(Refer Slide Time: 27:29)

**Joint Density ...Contd.**

- From the figure we can see that the point  $A(z,w)$  gets mapped on to the point  $A'(x_i, y_i)$ .
- Similarly the other points also
- Thus  $A'B'C'D'$  represent an equivalent parallelogram in the  $xy$  plane with area  $\Delta_i$
- Now the probability equation described previously can be rewritten as:

$$\sum_i \{P\{X, Y\} \in \Delta_i\} = \sum_i f_{XY}(x_i, y_i) \Delta_i$$

Probability Methods in Electrical Engineering: Dr. Rajib Halty, IIT Kharagpur 15

Then, we can express that from the figure, we can see that the point  $A(z, w)$  gets mapped on to the point  $A'(x_i, y_i)$ . So, this  $A$  is mapped to the point  $A'$  whose coordinates are  $x_i, y_i$ . Now, similarly other points also means other that  $B', C', D'$  are also will be  $A'$ , will be mapped in a similar way. So, thus the  $A' B' C' D'$  represent equivalent parallelogram in the  $x, y$  plane with the area  $\Delta_i$  what we have just now shown in the, in the, **in the**, figure.

So, now, the probability equation describe previously can be  $A$ , can be, rewritten as that this summation of this all this, for this all this representative area, that is, if it is belong that  $P(X, Y)$ , the combination belongs to this. That, that representative area  $\Delta_i$  should be the summation of the, for the all this representative point  $x_i, y_i$  multiplied by their elemental area. So, this is the joint density of the  $x, y$  between  $x$  and  $y$  and this is the area over which we are interested to know how much probability is there. So, we have to just multiply that area and its density.

(Refer Slide Time: 28:54)

**Joint Density ...Contd.**

- Equating both the equation:

$$f_{ZW}(z, w) = \sum_i f_{XY}(x_i, y_i) \frac{\Delta y}{\Delta z \Delta w}$$

- Let  $g_1$  and  $h_1$  represents the **inverse transformation**  
i.e.  $x_i = g_1(z, w)$  and  $y_i = h_1(z, w)$
- When the point  $A(z, w)$  moves to  $A'(x_i, y_i)$ , the other points:  
 $B(z + \Delta z, w)$  moves to  $B'$ ,  $C(z, w + \Delta w)$  moves to  $C'$ ,  
and  $D(z + \Delta z, w + \Delta w)$  moves to  $D'$

Probability Methods in Electrical Engineering: Dr. Rajib Halty, IIT Kharagpur 16

Now, if we equate the both the equations now from the whatever the equation that you got from here and the equation that we have represented here. So, both we are, both we are referring to the same probability and express one in the  $z, w$  plane; other one is the one on the  $x, y$  plane. So, you can equate these two as the, as the, probability that we are looking for is the, **is the**, same probability. So, these two are now equated to get that  $f_{ZW}$  is equal to single equal to of this function, and so, this  $\Delta z \Delta w$  is taken here as  $\Delta x \Delta y$  in that denominator.

Now, let that this  $g$  one and  $h$  one represent the inverse transformation. So, inverse transformation means that, we have that  $z$  equals to  $g(x, y)$ . So, now, we are just representing it that in terms of the  $x, y$ , we are representing in terms of the  $z, w$ . Just like that we are looking for the solution for this  $x$  and  $y$ . So, this is so, whatever the function through  $h$ , it is represented we are just denoting  $h$  as the  $g_1$  which is nothing but the inverse function to represent the  $x$ , and similarly, for the inverse function of the  $h$  is nothing but the  $h_1$ .

When the point  $A(z, w)$  moves to this  $A'(x_i, y_i)$ , the other points  $B(z + \Delta z, w)$  moves to  $B'$ ;  $C(z, w + \Delta w)$  will move to  $C'$  and  $D$ . I think it will be better to explain from this fifth figure directly. This is as I was just telling that  $A$  is having the coordinate  $z, w$ . This is mapped through  $A'$ . Now, what is the coordinate of this  $B$ ?  $B$  coordinate is nothing but it is  $z + \Delta z$  and  $w$  and coordinate of  $C$  will be  $z, w + \Delta w$ .

plus delta w and coordinate of d will be plus delta z, w plus delta w. So, these points are being mapped to this A prime, B prime, C prime and D prime. So, now, as these are mapped like this, I think the map will be the better word instead of this moves. It will be mapped through this point.

(Refer Slide Time: 31:33)

**Joint Density ...Contd.**

□ Thus co-ordinates of B' are:

$$g_1(z + \Delta z, w) = g_1(z, w) + \frac{\partial g_1}{\partial z} \Delta z = x_i + \frac{\partial g_1}{\partial z} \Delta z$$

and  $h_1(z + \Delta z, w) = h_1(z, w) + \frac{\partial h_1}{\partial z} \Delta z = x_i + \frac{\partial h_1}{\partial z} \Delta z$

□ The co-ordinates of C' :

$$x_i + \frac{\partial g_1}{\partial z} \Delta w \quad \text{and} \quad x_i + \frac{\partial h_1}{\partial z} \Delta w$$

Probability Methods in Electrical Engineering: Dr. Rajib Halty, IIT Kharagpur 17

Then, what we can write that the coordinates of the B prime can be written as this g. There is an inverse function  $g_1$   $h_1$  plus delta z, w is equal to  $g_1$  z w plus its derivative at that point multiplied by what is the change; that means, the delta z. So, we know this one from this fundamental theory of this calculus. So, this can be again as you know the, this is the  $x_1$  plus  $dg_1$  by  $dz$  multiplied by their value of the change, that is, delta z. Similarly, this  $h_1$  z plus delta z comma w can be represented by  $x_i$  plus delta  $dh_1$   $dz$  multiplied by this delta z. The coordinates of C prime will be now this one that similarly that this is for the B prime this is for the C prime  $x_i$  plus  $dg_1$   $dw$  and  $x_i$  plus  $dh_1$   $dw$ .

(Refer Slide Time: 32:39)

**Joint Density ...Contd.**

□ Thus area of A'B'C'D'

$$\Delta_i = (A'B') (A'C') \sin(\theta - \phi)$$

$$= (A'B' \cos \phi) (A'C' \sin \theta) - (A'B' \sin \phi) (A'C' \cos \theta)$$

□ From the previous equations, it can be written as:

$$A'B' \cos \phi = \frac{\partial g_1}{\partial z} \Delta z \quad A'C' \sin \theta = \frac{\partial h_1}{\partial w} \Delta w$$

$$A'B' \sin \phi = \frac{\partial h_1}{\partial z} \Delta z \quad A'C' \cos \theta = \frac{\partial g_1}{\partial w} \Delta w$$

 Probability Methods in  
Civil Engineering

Dr. Rajib Baiti, IIT Kharagpur

18

Similarly, that, so, thus the total area, that the area that we are talking about in this new, in this x y plane is that A prime B prime C prime D prime is nothing but the A prime B prime multiplied by A prime C prime sign of theta minus phi. So, there is a kind of distortion that you are taking through this. So, this A prime B prime cos phi so after this trigonometrical rearrangement, we can get that.

So, this A prime B prime cos phi is nothing but  $\frac{\partial g_1}{\partial z} \Delta z$  multiplied by  $\Delta z$ , and similarly, the other points can also be represented by this derivative their rate of change multiplied by their amount of total small change. So, this can be, again this figure can be referred to basically we are, **we are**, what we are obtaining is the total area, total area, total representative area that is on the plane x y. So, these are the values we got, and if we just put it back to this equation, we will get what is the total area  $\Delta i$ .

(Refer Slide Time: 33:56)

**Joint Density ...Contd.**

□ Therefore

$$\Delta_i = \left( \frac{\partial g_1}{\partial z} \frac{\partial h_1}{\partial w} - \frac{\partial g_1}{\partial w} \frac{\partial h_1}{\partial z} \right) \Delta z \Delta w$$

and

$$\frac{\Delta_i}{\Delta z \Delta w} = \left( \frac{\partial g_1}{\partial z} \frac{\partial h_1}{\partial w} - \frac{\partial g_1}{\partial w} \frac{\partial h_1}{\partial z} \right) = \begin{vmatrix} \frac{\partial g_1}{\partial z} & \frac{\partial g_1}{\partial w} \\ \frac{\partial h_1}{\partial z} & \frac{\partial h_1}{\partial w} \end{vmatrix}$$

□ The determinant on the right side of represents the absolute value of the Jacobian  $J(z, w)$  of the inverse transformation

 Probability Methods in Electrical Engineering: Dr. Rajib Baitty, IIT Kharagpur 19

This is exactly what is done here and we got this form. Now, what we are interested in now is that this  $\Delta_i$  by  $\Delta z \Delta w$ . So, this is the point that we got here. So, this one we just want to, want to obtain. So, this expression now can be defined through this one, that is, this will be cancelled and this  $\Delta_i$  which is the inverse function of this  $g_1$   $z$   $h_1$   $w$   $g_1$   $w$   $h_1$   $z$ .

Now, this can also be expressed in terms of the determinant of the matrix of this one. So, this multiplied by this minus this multiplied by this. So, this is the, now this determinant, if you see, this is the Jacobian of this, of this Jacobian represented by the  $z, w$ . Now, if we recall when we are, when we are interested to know the single function, then also we got the similar Jacobian consist of this only one element and that one element can be seen here as this one by one this one. So,  $g_1$   $z$ , so, which was the inverse function, inverse function, of that one and this determinant we use in case of this in this single random variable.

Now, when it is becoming that two random variables, two functions, then we are getting a 2 by 2 matrix for which the determinant is nothing but its Jacobian. Similarly, if there are three, three functions, then obviously, if there are three functions and three random variables, this will be your 3 by 3 matrix for which the determinant needs to be evaluated which is nothing but the Jacobian of, of the three random variables. So, here, we are just talking about two random variables.

(Refer Slide Time: 35:55)

### Joint Density ...Contd.

$$J(z, w) = \begin{vmatrix} \frac{\partial g_1}{\partial z} & \frac{\partial g_1}{\partial w} \\ \frac{\partial g_2}{\partial z} & \frac{\partial g_2}{\partial w} \end{vmatrix}$$

□ Substituting

$$f_{zw}(z, w) = \sum_i J(z, w) f_{xy}(x_i, y_i)$$

$$= \sum_i \frac{1}{|J(x_i, y_i)|} f_{xy}(x_i, y_i) \quad \text{since} \quad |J(z, w)| = \frac{1}{|J(x_i, y_i)|}$$

Probability Methods in Electrical Engineering: Dr. Rajib Baitty, IIT Kharagpur 20

So, I, we got that this is the Jacobean, and again from the same equation where we are just putting that is delta i divided by delta z multiplied by delta w that is replaced by this Jacobean. Now, to get that a close form, form. So, this is the joint density between this zw which is nothing but the, this joint density of this x y multiplied by its Jacobean and it is summing up for the all the possible solution, all the possible roots, and this one obviously we have to express in terms of this z and w that this x y, the joint density between x and y. So, this is the final form if we are having the two functions out of two random variables.

(Refer Slide Time: 36:45)

### Joint Density ...Contd.

□ Generalizing the one-to-one transformation can be represented as:

□ Let  $X_1, \dots, X_m$  be a multiple random variable with continuous pdf  $f_{X_1, \dots, X_m}(x_1, \dots, x_m)$ . The pdf of the multiple random variable  $Y_1, \dots, Y_n$  defined by a set of one-to-one transformations  $Y_i = g_i(X_1, \dots, X_m)$  for  $i = 1, \dots, m$  is given by

$$f_{Y_1, \dots, Y_n}(y_1, \dots, y_n) = |J| f_{X_1, \dots, X_m}[h_1(y_1, \dots, y_n), \dots, h_m(y_1, \dots, y_n)]$$

Probability Methods in Electrical Engineering: Dr. Rajib Baitty, IIT Kharagpur 21

Now, if we want to generalize, that is, one to one transformation, so, remember that what we forgot here. To mention that, this is a, this is their only for when we are talking that there are some one to one transformation, then what will happen? The, so, one to one transformation means there will be only one root, and that one when we are talking about that one to one root, so that means there is no need of this summation that this  $f_z w$  will be equals to the Jacobean multiplied by their that or joint density of the original random variable express in terms of  $z$  and  $w$ . That is important.

So, here, so, if let that  $x_1 x_2 \dots x_m$  be the multiple random variable with a continuous p d f and the continuous joint, **joint**, p d f which is  $f$  of  $x_1 x_2 \dots x_m$  express in terms of  $x_1 x_2$  up to  $x_m$  and the p d f of the multiple random variable  $y_1 y_2$  up to  $y_m$  defined by the set of one to one transformation. Say that  $y_1$  equals to  $g_1$ . This  $g_i$ , this is the function  $g_i$  of this  $x_1 x_2 \dots x_m$  for  $i$  equals to 1 to  $m$  and this is given by again from the same principle, that is, this new joint density is equals to the Jacobean multiplied by the original joint density function express in terms of their that  $y_1 y_2 \dots y_m$  that Jacobean look like this.

(Refer Slide Time: 38:16)

### Joint Density ...Contd.

where the inverse transformation is denote by:

$$x_1 = h_1(y_1, \dots, y_n), \dots, x_m = h_m(y_1, \dots, y_n)$$

and

$$J = \begin{vmatrix} \frac{\partial x_1}{\partial y_1} & \frac{\partial x_1}{\partial y_2} & \dots & \frac{\partial x_1}{\partial y_n} \\ \frac{\partial x_2}{\partial y_1} & \frac{\partial x_2}{\partial y_2} & \dots & \frac{\partial x_2}{\partial y_n} \\ \vdots & \vdots & \ddots & \vdots \\ \frac{\partial x_m}{\partial y_1} & \frac{\partial x_m}{\partial y_2} & \dots & \frac{\partial x_m}{\partial y_n} \end{vmatrix}$$

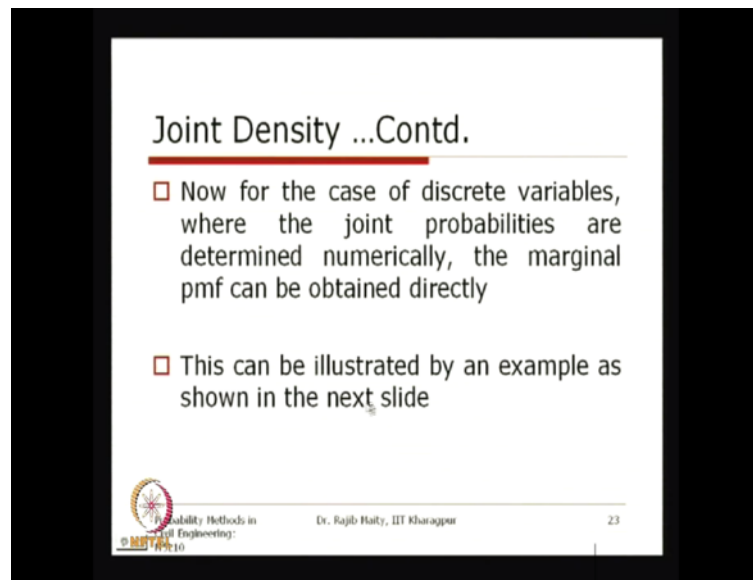

Probability Methods in  
Electrical Engineering

Dr. Rajib Halty, IIT Kharagpur

(Refer Slide Time: 38:30)

**Joint Density ...Contd.**

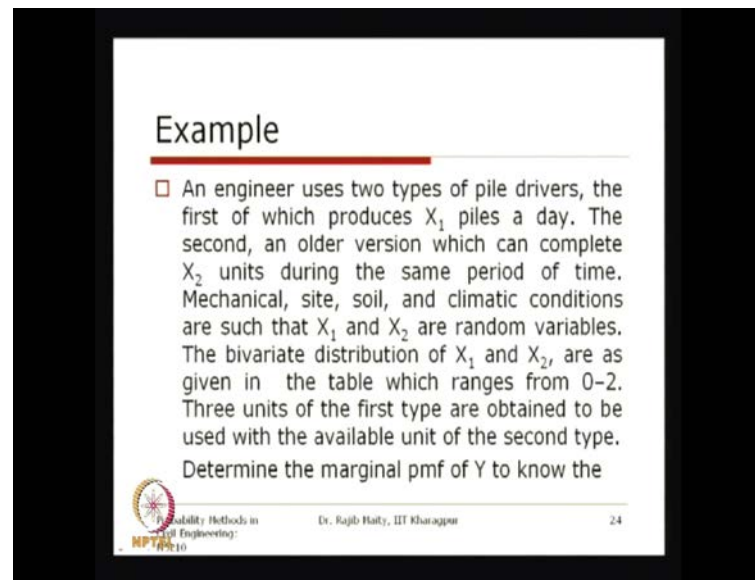

- Now for the case of discrete variables, where the joint probabilities are determined numerically, the marginal pmf can be obtained directly
- This can be illustrated by an example as shown in the next slide

Probability Methods in Electrical Engineering  
Dr. Rajib Halty, IIT Kharagpur  
23

So, these are the  $x_1, x_2, x_3$  are the original random variable and  $y_1, y_2$  are their function and this is the joint Jacobean and this Jacobean has been multiplied the, that absolute value of that Jacobean. Now, if we take the case of this discrete variable, that is, where the joint, joint, probabilities are the determined numerically and it is concentrated at some specific point.

The marginal pmf can be obtained directly, and how we do it? It will better explain in terms of one example, and after we just discuss this example of this, **of this**, discrete random variable that is to pmf. After that, we will take it for the case whatever in case of the continuous random variable what we have discussed now. Now, for this pmf, how we can do it? We have taken one example and we will see that, that case means the point to point basis we will just evaluate what is their, what is the distribution.

(Refer Slide Time: 39:26)

**Example**

□ An engineer uses two types of pile drivers, the first of which produces  $X_1$  piles a day. The second, an older version which can complete  $X_2$  units during the same period of time. Mechanical, site, soil, and climatic conditions are such that  $X_1$  and  $X_2$  are random variables. The bivariate distribution of  $X_1$  and  $X_2$ , are as given in the table which ranges from 0–2. Three units of the first type are obtained to be used with the available unit of the second type. Determine the marginal pmf of  $Y$  to know the

Reliability Methods in Engineering: MPTA 19910

Dr. Rajib Halty, IIT Kharagpur

24

So, we have taken one example here. An engineer uses two types of pile drivers, the first of which produce  $x_1$  pile a day, and the second and second one is an older version which can complete  $x_2$  unit during the same period of time. Mechanical conditions, site conditions, soil conditions, climatic conditions, all these conditions can influence on this  $x_1$  and  $x_2$  so that this  $x_1$  and  $x_2$  are treated as the random variable.

The bivariate distribution of this  $x_1$  between the  $x_1$  and  $x_2$  joint pmf are given in the table and which ranges from this 0 to 2. So, 0 to 2, two units. So,  $x_1$  can take the values 0, 1, 2 and  $x_2$  also can take the values 0, 1, 2 and their joint pmf is shown in the next slide. What we are interested? The three units of the first type are obtained to be used with the available unit of the second type. Determine the marginal pmf of  $y$  to know the distribution of the random variable  $y$  equals to  $3x_1$  plus  $x_2$ .

(Refer Slide Time: 40:38)

Example...Contd.

distribution of random variable  $Y = 3X_1 + X_2$ .

	$X_2 = 0$	$X_2 = 1$	$X_2 = 2$	$P_{X_1}(x)$
$X_1 = 0$	0.06	0.11	0.14	0.31
$X_1 = 1$	0.12	0.16	0.22	0.5
$X_1 = 2$	0.04	0.06	0.09	0.19
$P_{X_2}(x)$	0.22	0.33	0.45	$\Sigma = 1$

 Probability Methods in  
Civil Engineering:   
Dr. Rajib Hait, IIT Kharagpur 25

So, our function here is that  $3x_1 + x_2$ , and what is supplied is that there joint density is given here, that is, when  $x_1$  equals to 0 and  $x_2$  is also equals to 0, it is 0.06. When  $x_1$  equals to 0 and  $x_2$  equals to 1, it is 0.11. Like this 3 by 3 matrix is given here, and you know this last column is the marginal of this  $x_1$  and this is the marginal of the  $x_2$ . You know that total summation will be equals to 1.

So, now to know the distribution, the marginal distribution of this  $y$ , what we can do easily because this is only that 3 by 3 matrix only, what we can do is that we will take this specific value what the  $y$  can take. So, if  $x_1$  is 0 and  $x_2$  is 0, then the  $y$  also will be 0 and the maximum value of the  $y$  will be obtain when this  $x_2$  and  $x_1$  both are maximum, that is, the  $x_1$  equals to 2 and  $x_2$  equals to 2; that means, the  $y$  will be  $3 \times 2 + 2$ , so, 8. So,  $y$  can take a value from 0 to 8. So, these total nine discrete values can be taken by  $y$ . And what we are interested to know? What is the probability distribution that is the p.m.f for the  $y$ .

(Refer Slide Time: 42:10)

Example...Contd.

Sol.:

The marginal pmf of  $Y=3X_1+X_2$  from the output per day is as shown

Y	$X_1$	$X_2$	$P_Y(Y)$
0	0	0	0.06
1	0	1	0.11
2	0	2	0.14
3	1	0	0.12
4	1	1	0.16
5	1	2	0.22
6	2	0	0.04
7	2	1	0.06
8	2	2	0.09
$\Sigma=1$			

Dr. Rajib Hait, IIT Kharagpur

26

And now, if we just take it by their marginal p m f of they just 1 by 1, that is, when the y equals to 0, that means the x 1 equals to 0 and x 2 equals to 0, we know that their joint density is 0.6. Similarly, for the all such combination of this x 1 and x 2, we can, we know what is their joint probability and we know what is the value of the y.

So, when we are, **when we are**, interested to know what is the marginal distribution of y, so these values we should see, that is, y equals to 0, y equals to 1, y equals to 2 up to y equals to 8, and for this, what is their probability; for this, which is shown in the last column. So, this is the, **this is the**, p m f for the y and y can take nine discrete values and their probabilities corresponding probabilities are shown in the last column of this table. So, this is for the discrete case where this is a very small problem, where we can just pick up the corresponding values directly.

(Refer Slide Time: 43:11)

**Another Example**

Q. The benefits  $X$  and costs  $Y$  of a particular scheme are treated as random variables on account of numerous factors considered to be unpredictable. From some trial calculations based on past projects, the joint pdf is assumed to follow, bivariate negative exponential distribution:

$$f_{X,Y}(x,y) = e^{-(x+y)} \quad x, y \geq 0$$

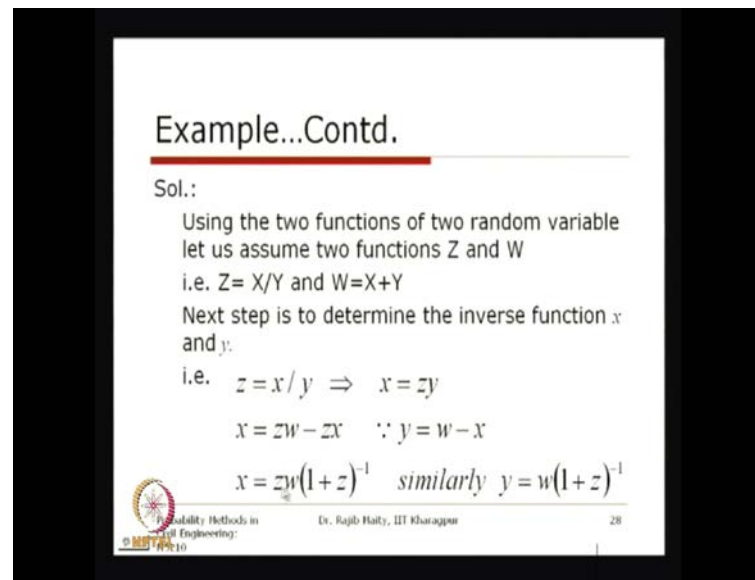

Determine the benefit-to-cost ratio  $X/Y$ .

Probability Methods in Civil Engineering: Dr. Rajib Halty, IIT Kharagpur 27

Now, if we take one problem which is where the, where the, random variables are continuous and we know their joint distribution and we want to know the joint distribution of the other two random variable which are the function of this original random variable. Once this example is taken through this cost benefit ratio of the project of some civil engineering project is the benefits  $x$  and the cost  $y$  of a particular scheme are treated as to be the random variable on the account of the numerous factors considered to be unpredictable.

From the trial calculation based on the first projects and the joint pdf is assume to follow a bivariate negative exponential distribution which is represented by this that  $f_{X,Y}(x,y)$  is equals to  $e^{-(x+y)}$ , where this  $x$  and  $y$  both are greater than equal to 0, and what we have to determine? Determine the density, probability density cost to benefit ratio, so,  $x$  by  $y$ . So, this one is the benefit is  $x$  and this  $y$  is the cost. Their joint density is this express in this form and we are interested to know what is the probability density of this benefit to cost ratio, that is,  $x$  by  $y$ . Now, see here, there, there, are two random variables -  $x$  and  $y$ , and one their joint distribution is given and we are looking for one function here.

(Refer Slide Time: 44:46)

**Example...Contd.**

**Sol.:**

Using the two functions of two random variable  
let us assume two functions Z and W  
i.e.  $Z = X/Y$  and  $W = X + Y$   
Next step is to determine the inverse function  $x$   
and  $y$ .  
i.e.  $z = x/y \Rightarrow x = zy$   
 $x = zw - zx \quad \therefore y = w - x$   
 $x = zw(1+z)^{-1} \quad \text{similarly } y = w(1+z)^{-1}$

Reliability Methods in  
Engineering: Dr. Rajib Halty, IIT Kharagpur 28

Now, as I wastelling before I start these two, two, functions. Sometimes this can also be done the way that we have done is there if there is only one function isasked for that. Whatever we have done earlier, that can be aused that theory to get what is the, what is their ratio, but we will just see through this example that, if we introduce another new randomvariable which may be not of our interest so far as the problem is concerned, but the problem can be solved very easily, because we will first find out their joint density, and from the joint density,we will find out what is the marginal distribution. This is what is explained through this problem is that.

So, one function, one function is the  $z$  equals to  $x$  by  $y$  and the other one we have just introduced is that  $w$  equals to  $x$  plus  $y$ . So, sometime the solution aremeans the joint, **joint**, density will depend on what is the new function that we have introduced, but so far as the marginal isconcerned, that marginal of this  $z$  that will remain same. So, generally a very simple function is assumed as this, as this function so far to make theit is calculationmake the calculation simple.

So, the next step is to determine the inversefunction of  $x$  and  $y$ , that is,  $z$  equals to  $x$  by  $y$ . So,  $x$  equals to  $z y$  and  $x$  equals to  $z w$  minus  $z x$ , that is,  $y$  equals to,  $y$  equals to  $w$  minus  $x$ . So,  $x$  equals to  $z w$  into  $1$  plus  $z$  minus  $1$ . Similarly,  $y$  is equals to  $w$  into  $1$  plus  $z$  y. So, what we have done? These are the two functions are there and we are, what we are doing

is, there we are getting the inverse function first because we know that we have to get this inverse function to get its Jacobean, **Jacobian**.

(Refer Slide Time: 46:40)

**Example...Contd.**

□ We have

$$\begin{aligned}
 f_{ZW}(z, w) &= |J| f_{XY}(x, y) \\
 &= |J| f_{XY}[zw(1+z)^{-1}, w(1+z)^{-1}] \\
 &= |J| e^{-[zw(1+z)^{-1} + w(1+z)^{-1}]} = |J| e^{-w}
 \end{aligned}$$

□  $|J|$  is:

$$J(z, w) = \begin{vmatrix} \frac{\partial x}{\partial z} & \frac{\partial x}{\partial w} \\ \frac{\partial y}{\partial z} & \frac{\partial y}{\partial w} \end{vmatrix} = \begin{vmatrix} w(1+z)^{-2} & z(1+z)^{-1} \\ -w(1+z)^{-2} & (1+z)^{-1} \end{vmatrix}$$

Probability Methods in Electrical Engineering: Dr. Rajib Halty, IIT Kharagpur 29

So, once we get this one, then we calculate what is their Jacobean. This is the final form that we have to obtain, that is,  $f_{ZW}$  is equal to their Jacobean multiplied by the original density, and so, this original, original density when we are talking, we have to express it in terms of the  $z$  and  $w$  that I mention.

So, this in place of the  $x$ , we are writing that  $z w (1 + z)^{-1}$  and  $w$  into  $(1 + z)^{-1}$ . So, which are getting from this  $x$  and  $y$  here and this is multiplied by this Jacobean and this joint density also we know that  $e^{-x+y}$ . So, this one plus this one which we can simplify to get that  $z$  equals to  $e^{-w}$ . So, what is pending is that we just want to know what is this Jacobean and Jacobean is you know that this is  $\frac{\partial x}{\partial z} \frac{\partial y}{\partial w} - \frac{\partial x}{\partial w} \frac{\partial y}{\partial z}$  and this Jacobean if we just solve, we will get this form.

(Refer Slide Time: 47:47)

### Example...Contd.

$$J(z, w) = \begin{vmatrix} w(1+z)^{-2} & z(1+z)^{-1} \\ -w(1+z)^{-2} & (1+z)^{-1} \end{vmatrix} = w(1+z)^{-4} + wz(1+z)^{-3} \\ = w(1+z)^{-2}$$

□ Therefore, the bivariate pdf of Z and W is given by:

$$f_{ZW}(z, w) = |J| e^{-w} \\ = w(1+z)^{-2} e^{-w}$$

Reliability Methods in  
Civil Engineering

Dr. Rajib Halty, IIT Kharagpur

30

And after doing this calculation, we will get. Finally, what we will get is the  $w$  into  $1$  plus  $z$  power minus  $2$ . So, this is the Jacobian so that, so that, joint distribution will be its Jacobian exponential minus  $w$ , so,  $w$  into  $1$  plus  $z$  power minus  $2$   $e$  power minus  $w$ . So, this is the joint density between  $z$  and  $w$ .

(Refer Slide Time: 48:13)

### Example...Contd.

□ The benefit-to-cost ratio can be given by the marginal pdf of Z:

$$f_Z(z) = \int_0^{\infty} w(1+z)^{-2} e^{-w} dw \\ = (1+z)^{-2} \left[ -(1+w)e^{-w} \right]_0^{\infty} \\ = (1+z)^{-2} \quad \text{for } z \geq 0 \\ = 0 \quad \text{elsewhere}$$

Reliability Methods in  
Civil Engineering

Dr. Rajib Halty, IIT Kharagpur

31

Now we are we want to know what is the, **what is the**, density of this  $z$  only because  $z$  is the benefit to cost ratio. So, we have to calculate its marginal. Now, when we are calculate this marginal that means, the other variable has to be margined out by integrating over its entire range which is 0 to infinity. So, when we are expressing this one, here we are, we are, suppose to write that this  $z$ ,  $w$  is should be greater their support. So,  $z$ ,  $w$  is greater than equal to 0. I hope it was mentioned earlier this form like this that  $x$ ,  $y$  is greater than equal to 0 this is its support.

So, we are just integrating out that  $w$  to get the marginal density of that  $z$ , and this is nothing but if we just do this integration, we will get the form as that 1 plus  $z$  power minus 2 for  $z$  is greater than equal to 0, and otherwise, it is 0. So, this marginal density of  $z$  equals to 1 plus  $z$  power minus 2. So, this is the density of this cost to benefit, that benefit to cost ratio that is  $x$  by  $y$ .

(Refer Slide Time: 49:25)

**Linear Function**

□ Let  $Z=aX+bY$  and  $W=cX+dY$  and if  $ad-bc \neq 0$ , then the linear function has one and only one solution:

$$x = Az+Bw \quad \text{and} \quad y = Cz+Dw$$

where  $A = d/(ad-bc)$ ,  $B = -b/(ad-bc)$ ,  
 $C = -c/(ad-bc)$ ,  $D = a/(ad-bc)$

□ Also  $J(x,y) = ad-bc$ , thus

$$f_{ZW}(z,w) = \frac{1}{|ad-bc|} f_{XY}(Az+Bw, Cz+Dw)$$

Probability Methods in Civil Engineering  
 Dr. Rajib Hatty, IIT Kharagpur  
 32

Now, we will take up some special cases where that through this two, two function. The first one is that linear, linear functions only. Now, linear functions means when there are, we are considering to adjust multiplying it by some constant and just there we are adding them up, this is the, **this is the**, linear function, and we will just see that for a linear function, how the final form looks like and also we will take upon one thing of this joint normality. If the original distribution is the is joint normal distribution, then what will happen to that, **to that**, to that, resulting joint distribution.

So, first this is the linear, linear function. Let that  $z$  equals to  $a x + b y$  and  $w$  equals to  $c x + d y$ , and if that  $d - b c$  is not equal to 0, this is one condition because this is what is the coefficient of  $x$  and coefficient of  $y$  minus the multiplication of the coefficient of  $y$  and coefficient of  $c$ . If this is not equal to 0, we will see in a minute why this is one requirement. Then the linear function has one and only one solution and this solution is that  $x$  equals to  $a z + b w$  and  $y$  equals to  $c z + d w$ , where this capital  $A B C D$  are the constant which can be expressed in terms of the lower case of this constant the  $A B C D$  through this expression.

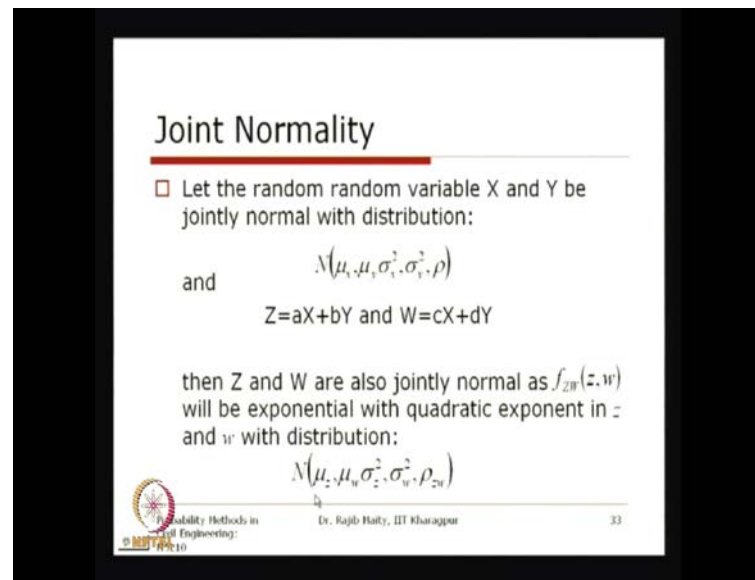

This is just basically what we are doing? We are getting their inverse function. So, once we know this inverse, one inverse function, and also we know that what is the Jacobean of this  $x y$  and this Jacobean of the  $x y$  will be we can just express that  $\det J_{x,y}$  which is  $d - b c$ .

So, thus this joint density is that  $z w$  is equals to  $1$  minus  $1$  by  $a d - b c$  and  $f(x, y) = \frac{1}{a d - b c} \exp(-a z - b w)$ . Remember here, here, we are using this Jacobean of  $x y$ . We can use the Jacobean of this  $z w$  also be depending on where we are putting this  $1$  by  $a, 1$  by this Jacobean that we are doing. In the earlier example, what we did is the, we just multiplied with the Jacobean and that Jacobean was between the function, that is, the  $z$  and  $w$ . So, based on that where we are putting this.

So, now, if we know these functions, so, if it is a linear function, we know their coefficient; we can easily calculate what is this capital  $A B C D$  and we can express in terms of their  $z$  and  $w$  and we will, and we will divide it by this function this Jacobean and that will give the joint density here. Now, you see, it is as this is in the denominator. So, if this is 0, then we will not get the solution which will be infinity. So, this if this is not equal to 0, then we can get their, **their**, solution at that, what is the joint density between  $z w$ ,  $z$  and  $w$ .

(Refer Slide Time: 52:29)

**Joint Normality**

□ Let the random variable  $X$  and  $Y$  be jointly normal with distribution:

$$N(\mu_x, \mu_y, \sigma_x^2, \sigma_y^2, \rho)$$

and

$$Z = aX + bY \text{ and } W = cX + dY$$

then  $Z$  and  $W$  are also jointly normal as  $f_{ZW}(z, w)$  will be exponential with quadratic exponent in  $z$  and  $w$  with distribution:

$$N(\mu_z, \mu_w, \sigma_z^2, \sigma_w^2, \rho_{zw})$$

Probability Methods in Civil Engineering: Dr. Rajib Baitty, IIT Kharagpur 33

Now, the joint normality let the random variables  $x$  and  $y$  be the jointly normal with the distribution. You know that it is  $\mu_x, \mu_y, \sigma_x^2, \sigma_y^2$  and  $\rho$ . So, this  $\mu_x$  is the mean of this random variable  $x$ ;  $\mu_y$  is the mean of the random variable  $y$ .  $\sigma_x^2$ 's square is the variance of the random variable  $x$  and  $\sigma_x \sigma_y$  square is the variance of the random variable  $y$  and  $\rho$  is the correlation coefficient between  $x$  and  $y$ . There will be a comma here between  $\mu_y$  and  $\sigma_x^2$ 's square.

So, this is a joint normal distribution and the functions that we are talking about the linear function again that  $a x + b y$  and  $w$  equals to  $c x + d y$ . If we have this function, then we can solve it to know that what is its joint distribution; then it can be shown that this  $z$  and  $w$  are also jointly normal as this  $f_{ZW}$  will be exponential and the quadratic exponent in this  $z$  and  $w$  with the distribution  $N(\mu_z, \mu_w, \sigma_z^2, \sigma_w^2, \rho_{zw})$ . So, this is the correlation between  $z$  and  $w$  variance of  $w$ . This is variance of  $z$ . This is mean of  $w$ ; this is mean of  $z$ ; obviously, again one comma will be there between  $\mu_w$  and  $\sigma_z^2$  square.

(Refer Slide Time: 54:05)

**Joint Normality...Contd.**

And these parameters are directly computed as:

$$\mu_z = a\mu_x + b\mu_y$$

$$\mu_w = c\mu_x + d\mu_y$$

$$\sigma_z^2 = a^2\sigma_x^2 + 2ab\rho\sigma_x\sigma_y + b^2\sigma_y^2$$

$$\sigma_w^2 = c^2\sigma_x^2 + 2cd\rho\sigma_x\sigma_y + d^2\sigma_y^2$$

$$\rho_{zw} = \frac{ac\sigma_x^2 + (ad+bc)\rho\sigma_x\sigma_y + bd\sigma_y^2}{\sigma_z\sigma_w}$$

Probability Methods in Civil Engineering  
Dr. Rajib Halty, IIT Kharagpur  
34

And to know that, what is this  $\mu_z$  and  $\mu_w$ ? If we just solve this one we can say that,  $\mu_z = a\mu_x + b\mu_y$ . Similarly means it is just you can see that here, the way we are just adding, it is very easy to remember that this  $a$  multiplied by this mean of this and  $b$  multiplied by the mean of mean of this. So, this is basically we are taking the expectation of the both the side.

So, this is the mean or this is the mean of this  $w$  and this is the sigma,  $\sigma_z^2$  square. The variance of this  $z$  is that you know that this is multiplied by this square of the coefficient  $a$  square  $\sigma_x^2$ 's square  $b$  square  $\sigma_y^2$  square multiplied by a factor. If they are not independent, then this  $2ab\rho$  times their product of their standard deviation. Similarly, for this  $\sigma_w^2$  square is expressed through this one and their  $\rho_{zw}$  can also be expressed through this expression using the correlation coefficient between  $x$  and  $y$  here.

So, we will take up a problem on this one maybe in the next class on this joint normality. In many cases, there are some random variables where we can say that these are jointly normally distributed and we know their some linear functions we have to use for some of the Civil Engineering problem.

And if we know this expression, then we can easily get what is the joint distribution of their, of the new random variables there. In the next class, we will be, we will take up some as I told some of the problems on this one that the theory, that we discussed in the

last, last on these two random variable, may be one or two problems. We have already discussed may be one or two problem we will take, and after that, we will take you through that copula which will be used for this multiple random variables to know their joint, joint distribution from their marginal distribution. Thank you.
